American Medical Association

A MEDICAL JOURNAL CONTAINING THE

OFFICIAL RECORD OF THE PROCEEDINGS OF THE ASSOCIATION, AND THE PAPERS READ AT THE ANNUAL SESSION, IN THE SEVERAL SECTIONS, TOGETHER WITH THE

MEDICAL LITERATURE OF THE PERIOD

EDITED FOR THE ASSOCIATION UNDER THE DIRECTION OF THE BOARD OF TRUSTEES

BY

GEORGE H. SIMMONS, M.D.

VOLUME XLIV

JANUARY—JUNE

1905

CHICAGO
AMERICAN MEDICAL ASSOCIATION PRESS.
1905.

"The American Medical Association, though formally accepting and publishing the reports of the various Standing Committees (and Sections), holds itself wholly irresponsible for the opinions, theories or criticisms therein contained, except when otherwise decided by special resolution."—TRANSACTIONS, 1851.

OFFICERS OF THE AMERICAN MEDICAL ASSOCIATION

1904-1905

GENERAL OFFICERS

President—John H. Musser - - - - - - - - - - - - - Philadelphia.

President-Elect—Lewis S. McMurtry - - - - - - - - Louisville, Ky.

First Vice-President—Edward Jackson - - - - - - - - - - Denver.

Second Vice-President—James Hall Bell - - - - - - San Antonio, Texas.

Third Vice-President—F. C. Shattuck - - - - - - - - - - Boston.

Fourth Vice-President—B. C. Pennington (deceased) - - - Atlantic City, N. J.

General Secretary and Editor—George H. Simmons - - 103 Dearborn Ave., Chicago.

Treasurer—Frank Billings - - - - - - - - - - - - - Chicago.

Chairman Committee of Arrangements—K. A. J. Mackenzie - - - Portland, Ore.

BOARD OF TRUSTEES.

E. E. Montgomery, Philadelphia, 1905.
H. L. E. Johnson, Washington, D. C., 1905.
A. L. Wright, Carroll, Iowa, 1905.
William H. Welch, Baltimore, 1906.
Miles F. Porter, Ft. Wayne, Ind., 1906.
M. L. Harris, Secretary, Chicago, 1906.
W. W. Grant, Denver, 1907.
T. J. Happel, Chairman, Trenton, Tenn., 1907.
Philip Marvel, Atlantic City, N. J., 1907.

JUDICIAL COUNCIL.

P. Maxwell Foshay, Illinois.
George Ben. Johnston, Virginia.
D. C. Peyton, Indiana.
W. B. Russ, Texas.
F. H. Wiggin, New York.

COUNCIL ON MEDICAL EDUCATION.

Arthur Dean Bevan, Illinois.
Victor C. Vaughan, Michigan.
W. T. Councilman, Massachusetts.
J. A. Witherspoon, Tennessee.
Charles H. Frazier, Pennsylvania.

SECTION OFFICERS

PRACTICE OF MEDICINE—Chairman, Richard C. Cabot, 190 Marlboro St., Boston; Secretary, J. L. Miller, 100 State St., Chicago. Executive Committee—Frank A. Jones, Memphis, Tenn.; W. S. Thayer, Baltimore; Alexander Lambert, New York City.*

OBSTETRICS AND DISEASES OF WOMEN—Chairman, C. L. Bonifield, 432 West Fourth St., Cincinnati, Ohio; Vice-Chairman, F. F. Lawrence, Columbus, Ohio; Secretary, W. P. Manton, Detroit, Mich. Executive Committee—J. H. Carstens, Detroit, Mich.; A. Palmer Dudley, New York City; L. H. Dunning, Indianapolis.

SURGERY AND ANATOMY—Chairman, Maurice H. Richardson, 224 Beacon St., Boston; Secretary, Floyd W. McRae, Atlanta, Ga. Executive Committee—DeForest Willard, Philadelphia; James E. Moore, Minneapolis; Charles A. Powers, Denver, Colo.

HYGIENE AND SANITARY SCIENCE—Chairman, John S. Fulton, 1809 St. Paul St., Baltimore; Secretary, M. L. Price, 1532 Linden Ave., Baltimore. Executive Committee—Arthur R. Reynolds, Chicago; H. M. Bracken, Minneapolis; G. T. Swarts, Providence, R. I.

OPHTHALMOLOGY—Chairman, C. R. Holmes, Cincinnati, Ohio; Secretary, Albert E. Bulson, Jr., 219 West Wayne St., Fort Wayne, Ind. Executive Committee—Frank Allport, Chicago; John E. Weeks, New York City; Robert L. Randolph, Baltimore.

DISEASES OF CHILDREN—Chairman, John Lovett Morse, 70 Bay-State Road, Boston; Vice-Chairman, W. E. Darnall, Atlantic City, N. J.; Secretary, J. Ross Snyder, Birmingham, Ala. Executive Committee—H. M. McClanahan, Omaha; John C. Cook, Chicago; Charles G. Kerley, New York City.

STOMATOLOGY—Chairman, Vida A. Latham, Rogers Park, Ill.; Vice-Chairman, Edward C. Briggs, 129 Marlboro St., Boston; Secretary, Eugene S. Talbot, 103 State St., Chicago. Executive Committee—A. H. Peck, Chicago; M. L. Rhein, New York City; G. F. Eames, Boston.

NERVOUS AND MENTAL DISEASES—Chairman, J. H. McBride, Pasadena, Cal.; Secretaray, David I. Wolfstein, 22 West Seventh St., Cincinnati. Executive Committee—Richard Dewey, Wauwatosa, Wis.; F. W. Langdon, Cincinnati; H. T. Pershing, Denver.

CUTANEOUS MEDICINE AND SURGERY—Chairman, Douglas W. Montgomery, 1301 Van Ness Ave., San Francisco; Secretary, R. R. Campbell, 204 Dearborn St., Chicago. Executive Committee—Henry W. Stelwagon, Philadelphia; John A. Fordyce, New York City; Henry G. Anthony, Chicago.

LARYNGOLOGY AND OTOLOGY—Chairman, Robert C. Myles, 46 West Thirty-eighth St., New York City; Secretary, Otto T. Freer, 288 Huron St., Chicago. Executive Committee—G. Hudson Makuen, Philadelphia; George L. Richards, Fall River, Mass.; John F. Barnhill, Indianapolis.

PHARMACOLOGY—Chairman, Heinrich Stern, 56 East Seventy-sixth St., New York City; Secretary, C. S. N. Hallberg, 358 Dearborn St., Chicago. Executive Committee—George F. Butler, Chicago; Solomon Solis-Cohen, Philadelphia; O. T. Osborne, New Haven, Conn.

PATHOLOGY AND PHYSIOLOGY—Chairman, Winfield S. Hall, 2421 Dearborn St., Chicago; Secretary, Henry A. Christian, Harvard Medical School, Boston. Executive Committee—Frank B. Wynn, Indianapolis; Victor C. Vaughan, Ann Arbor, Mich.; Joseph McFarland, Philadelphia.

Address.

HISTORY OF THE CLINICAL RECOGNITION OF GASTRIC ULCER.[*]

JOHN C. HEMMETER, M.D.

Professor of Physiology, and Clinical Professor of Medicine, University of Maryland, Baltimore.

BALTIMORE.

Succinct histories of the development of clinical conceptions on special diseases are very rare. This is partially explicable by the scarcity of historical data concerning early clinical thinking and by the confusion that has been brought into the accounts of the classical writers of medicine by the facts that the identical disease is designated with different names by different authors, and also that the exact diagnosis was rarely verified by operation or autopsy.

In the following sketch of the history of the clinical recognition of gastric ulcer, conclusions were based only on such cases as were substantiated in the manner just mentioned. In the writing of Hippocrates we find no statement which would justify us in concluding that the "Father of Medicine" was familiar with ulcer of the stomach as we conceive it to-day.

It is stated (Lebert) that Hippocrates treated Pericles for intense abdominal pain (gastralgia) by hellebore and flaxseed poultices.[1] I shall return to the Hippocratic literature on this subject in the latter part of this article.

A careful review of a German translation of Galen reveals no knowledge of peptic ulcer, though undoubtedly both Hippocrates and Galen give accounts of vomiting of blood in the sequence of digestive disturbances and abdominal pain.

It is impossible to personally scrutinize the writings of the historical clinicians for any statement that might be interpreted as a distinct clinical recognition of gastric ulcer. According to Lebert,[2] from whom also Welch[3] has derived most of his information concerning the history of clinical recognition of peptic ulcer, it is not until the sixteenth century that a clinical record available for our purpose can be found. It occurs in the writings of Johann Bauhin, the elder brother of Caspar Bauhin (1550-1624), and may be found in "Boneti Sepulchretum." It refers to a physician's wife, 18 years old, who suddenly showed symptoms of a perforation into the peritoneum, and died four days afterwards. In her abdomen was discovered besides gas, fluids and food remnants, a perforation in the middle of the stomach near the fundus; there were black contents in the stomach and clotted blood had been evacuated by the bowels.

From the second half of the sixteenth century dates another observation by Marcellus Donatus, which refers to a man 59 years old, who, after continued vomiting and pains in the stomach, was found at the postmortem examination to have near the pylorus at the lower end of the stomach an ulcer—*tunicam interiorem exesam*—a very graphic descriptive expression.

Courtial describes an oval opening in the anterior part of the stomach, with callous edges in a young woman who had suffered from gastric symptoms since her youth.

Littré found in the case of a man who had suffered from various affections of the stomach, and finally from hemorrhages, a round ulcer near the pylorus.

One of the first ulcers leading to a fistula in the stomach which is recorded in the literature so far known, seems to be associated with a case of Duverney. Similar observations were described in the first half of the previous century by van Swieten, Klein, Wenker, Iodac, Atkinson, Petit, Eckmuller, Cireaud, Helm, and Kade. It is not, however, quite certain to what the trouble in the various cases might rightly have been attributed, whether to the presence of a simple ulcer, or to a circumscribed abscess of the stomach region or a combination of both. The probabilities are, however, that the observation of van Swieten and Wenker were genuine cases of peptic ulcer.

Records of cases of healed ulcer of the stomach we already possess for the sixteenth and seventeenth centuries, by Forestus and Schenk von Grafenberg (1531 to 1598). In this connection should be mentioned an observation from the close of the preceding century by Reil, in which the scar of a healed gastric ulcer had become adherent to the mesenteric glands. The radiant formation of such a scar at the lesser curvature of the stomach has been aptly described according to a specimen in Meckel's collection. Older observations concerning abnormal conditions of the form of the stomach, with median contraction, by Blase, Mangold, Heister, Sandifort, Sömmering, Morgagni, etc., allude in a measure to such ulcers. In a number of cases symptoms of chronic stomach trouble existed beforehand, and frequently mention is made of callous bands, which would point to scars of earlier existing ulcers. In the last century mention is often made of adhesions of the stomach to adjacent parts (Mead, Murray, Santessen, Westring, etc.) of rupture of the stomach (principally through an ulcer), of death from excessive hemorrhage, also mainly attributable to a chronic peptic ulcer.

A good brief description, with excellent illustrations, was given at the close of the eighteenth century (in 1793) by Matthew Baillie. To Matthew Baillie unquestionably belongs the credit of having first accurately described, in 1793, the anatomic peculiarities of simple gastric ulcer.[4] At a later date he published three good engravings of this disease.[5] Baillie's concise and admirable description of the morbid anatomy of gastric ulcer was accompanied by clinical data, and seems to have had little or no influence in directing increased attention to this disease.

---

[*] Address before the American Gastroenterologic Association, Atlantic City, June, 1904.

[1] I have seen this statement quoted also by Talmage in an address to medical graduates, but have not been able to trace the source nor authority for same.—J. C. H.

[2] Krankheiten d. Magens, Tübingen, 1877, p. 180.

[3] Pepper's System of American Medicine, vol. ii.

By far the best description of this disease up to the date of its publication is by Voigtel, at the beginning of the eighteenth century. The following description is quoted from Lembert:[1] "Frequently ulcers are found in the membranes of the stomach. Oftener they progress from the interior to the exterior; they are merely superficial cancers or perforations. They have in common a peculiar appearance. Frequently they are surrounded by an inflammatory thickening and hardness, and then again it is not possible to detect near or around them any distinctive abnormal formation of the stomach. They appear as if "a piece of the stomach had been cut out with a knife," and the edges so healed as to make a smooth boundary all around the opening; at times the gastric tissue about the opening has condensed." The subsequent remarks point likewise to an admirable knowledge with the whole evolution of the disease on the part of Voigtel and his contemporaries, Meikel, Reil, etc. The words used by Voigtel in describing the appearance of this gastric lesion, namely: "As if a piece of the stomach had been cut out with a knife."—remind one of the expression of Rokitansky[6] used much later, and which is much oftener quoted, namely: "As if a piece of the stomach had been cut out with a punch."

Many observations, accompanied by diverse commentaries, are found in the early scientific literature concerning spontaneous perforations of the stomach, the greater part of which may rightly be classed here.

Toward the end of the eighteenth century we encounter Hunter's theory of the origin of gastric perforations, attributing them to the erosion by the gastric juice; although based on the authority of Spallanzani, this hypothesis lost ground very rapidly, notwithstanding the support given it by a number of important au- orities. Carswell managed to bring it again into sitory favor. In the year 1800 Joseph Morin stated perforation of the stomach was a result of a pro- acted local inflammation of the gastric membranes. He likewise speaks of stagnation in the blood vessels, with a change in the direction of the flow of the blood and autodigestion, as some of the causes. According to the very pretty historic compilation of Lefevre, Lerons and Chaussier, in the year 1808, presented to the Paris Medical Association reports of their observations of perforated gastric ulcers accompanied by adhesions of the spleen.

Very interesting history also is found in the defense of a person by Chaussier against the charge of poisoning, in 1818, when the latter proved that a perforation of the stomach had taken place after previous prolonged ulceration. Similar cases have come up frequently since that time. Cruveilhier relates that there was a movement on foot to attribute the death of one of his cases of chronic gastric ulcer to poisoning, when he proved that the true cause of the perforation in question had been a previously existing ulcer in the stomach. The dissertation of 1819 by Lainé offers for those times very sound opinions about this perforation, and describes the deleterious action of the digestive fluid as succeeding ulceration. He also emphasizes the importance of studying the antecedents of a case. The expression "perforation by erosion" from now on appears more frequently. Lainé also recommends, for forensic reasons, not only chemical inquiry, but also an examination of those parts of the anatomy through which the alleged poison is supposed to have passed into the stomach.

Rausch, in his classification of gastric ruptures, designates those incident to a real ulcer, often with callous edges, as one of the main groups. Similar results are reached by Ebermaier, who, in addition to his own, cites cases by Henkel, Mole, Baron, Gérard, Desgranges, Trinius, Besker, Spitta, and Thomissen. To all these cases he attributes a chronic, many times unknown course, frequently with easily discernible symptoms, especially cardiac symptoms. The frequency with which the rupture takes place near the pylorus is pointed out by him, but he seems to be unable to determine the cause of this phenomenon. Cancer and ordinary inflammation, however, are not regarded as having causal significance.

In 1824, Abercrombie published a brief, but for his time a very remarkable description of this disease. Some of his observations clearly refer to the ulcus simplex; indeed one of the cases reported to him by Wood refers to a perforated ulcer of the duodenum. His confusion of cases of gastric cancer and other malignant growths with those of simple ulcer, shows how undefined his views were.

We now have become acquainted with two phases of the history of chronic ulcer—the first being one of the isolated observations beginning with the tenth century, the second beginning with the close of the eighteenth and with the early part of the nineteenth century, and occupying itself with the establishing of a collection of those isolated observations as done by Voigtel, but emphasizing more of the pathologic anatomic point of view; on the clinical side, too, much attention is paid to the perforation itself.

Cruveilhier has the distinction of being the first to subject this disease both clinically as well as anatomically to a thorough and intelligent pathologic examination. The tenth issue of his great "Pathological Anatomy," from the beginning of the third decade of the nineteenth century, 1829-1835, gives evidence of an extensive personal experience on the subject.

Cruveilhier[6] in the first volume of his work on Pathologic Anatomy, published between the years 1829 and 1835, for the first time clearly distinguished ulcer of the stomach from cancer of the stomach and from ordinary gastritis. He gave an authoritative and full description of gastric ulcer from the anatomic, the clinical and the therapeutic points of view.

Among his observations are those concerning the Greek professor, Gall, from the end of the year 1828 and beginning of the next; one from December, 1829, about a charcoal burner, who died soon after the perforation of his stomach; one from the beginning of the year 1830, concerning the famous chemist, Darcet; one from the same year concerning a gastric ulcer which had cicatrized—and with respect to this case we learn from his twentieth issue that the person in question died in 1834 from a perforated stomach. Not only are the anatomic aspects—i. e., rapidly developing, chronic ulcer, closing up, scarring over, perforation, hemorrhage from the coronary artery of the stomach, from the splenic artery, malformation of the stomach, contraction of the pylorus through the agency of scarring—well described, but also a good foundation is laid for clinical and therapeutic work.

We thus emerge into the modern phase, in which a correct and broad interpretation of anatomic and clinical facts of the influence of hygiene, diet and therapeutics takes place, and thus order and understanding are introduced into this chaos of observations.

In Germany we are indebted to Rokitansky for a classical treatise on the peptic ulcer, based on a large clinical and pathological experience, well analyzed. This excellent work became rapidly known.

Next to Cruveilhier, Rokitansky has had the greatest influence on the modern conception of gastric ulcer. In 1839 this pathologist gave a description of the disease based on an analysis of 79 cases.[7] The anatomic part of his description has served as a model for all subsequent writers on this subject everywhere. A few years later von Jaksch extended the pathologic knowledge of the gastric ulcer (to be sure, more from his clinical experience than from a strict analysis of bedside records), by a series of thorough clinical investigations.

From 1830 to 1840 observations and compilations appear frequently in the medical literature of almost all countries. According to Lebert,[1] rich collections for causal interpretation are found in the *Bulletins de la Société anatomique de Paris,* also in *Archives générales de Médicine,* in the "Annual Reports" of the last 20 years of Canstatt,[8] the Proceedings of the London Pathological Society, etc. Among the older journal articles and dissertations that have appeared is the Thesis of Duval in the year 1852 (Paris), one of the earliest of the better French compilations. Lebert[1] also refers to the publications of one of his pupils, Bisseger, as containing his own views often expressed in the Zürich clinic, and also an analysis of its rich material, together with clinical histories.

After Virchow, in 1855, developed his views on the hemorrhage-necrotic origin of the simple peptic ulcer, a series of good dissertations appeared under his editorial supervision, among which especial mention should be made of those by Steiner, 1868, and Wollman, 1868. Among the English authors, Crisp, Ashborne, Chambers, Habershon, Handfield-Jones, etc., but especially Brinton, have done excellent work. From the latter emanated the largest compilation, with excellent anatomical and clinical data. Habershon has also made valuable clinical additions to our knowledge of this disease.

From the beginning of scientific inquiry cited in the preceding, to the year 1868, there is, as we have seen, a vast accumulation of clinical data, but out of all of this literature, according to Lebert, not 100 are of genuine objective merit.

Cruveilhier's work of 1856, made known in the *Archives Generales de Medicine,* contains for those times and for the present no new matter beyond what was presented in his previous publications, but impresses us with the great anatomic and clinical experience of this wonderful pathologist.

Trousseau, in his *Clinique Medicale,* gives a review of the essentials, which acts in a stimulating manner on medical thinkers, but is, of course, incomplete, which is to be expected of clinical lectures, however important they otherwise may be.

Bamberger's description is an excellent sketch of the subject. The work of Ziemssen (in his Encyclopedia, Ziemssen's *Handbuch d. spec. Path. u. Therap.*), on the treatment of chronic gastric ulcer, represents the best knowledge of the Münich clinic.

As early as 1845 Schiff shows that hemorrhagic localized infiltrations of the mucous membrane of the stomach result from an irritation of certain parts of the brain. After a number of other experiments, he published the results of his investigations in his "*Leçon sur la digestion.*" In 1852 Lebert became acquainted for the first time with the hemorrhagic type of the growth of chronic gastric ulcer. In 1855 Virchow made known his views on this matter, and brought into general favor the acceptance of a hemorrhagic necrotic origin of the peptic ulcer. Müller has the distinction of having proved, in 1859, that the ligation of the portal vein results in numerous hemorrhagic erosions of the stomach, particularly in the pyloric region. Pavy later on showed the same thing in the case of larger ulcers through ligation of branches of the gastric artery. For the best and most exhaustive experiments on the circumscribed hemorrhagic infiltrates in the mucous membrane of the stomach, we are indebted to Ebstein.

Since the ushering in by Cruveilhier and Rokitansky of the modern era in the history of the gastric ulcer, the era of exact objective investigation, medical literature abounds in articles on this disease. But it can not be said that the importance of these works is at all commensurate with their number or that they have added very materially to the classical descriptions given by Cruveilhier and by Rokitansky. Perhaps most worthy of mention of the works of this later era are the article by Jaksch relating to symptomatology and diagnosis, and of Virchow relating to etiology, the statistical analyses by Brinton, and the contribution to the treatment of the disease by Ziemssen and by Leube.[9] In 1860, Ludwig Müller[10] published an extensive monograph on gastric ulcer. The most modern literature on the subject is contained in the works of Riegel.[11] Prof. Wm. H. Welch[12] gives a short résumé of the history of the clinical recognition and pathology of gastric ulcer, taken largely from Lebert. In the new *Handbuch der Geschichte der Medicin,* by Neuberger and Pagel,[13] the history of gastric ulcer is rather neglectfully treated. It seems that the author, George Korn, had no knowledge of the interesting studies of Abercrombie, Voigtel, Littré, Matthew Baillie, Cruveilhier and the other clinical and pathologic workers mentioned in the preceding. The article is interesting for the histology and pathology of digestion, the history of the stomach tube, etc., but for the history of the development of clinical ideas on any single gastric disease, little help can be obtained from this otherwise very interesting article. On page 693 of this article, Korn asserts that Hippocrates already described some of the symptoms of gastric ulcer as a special disease which was called *"sphacelous disease,"* or *"morbus niger,"* because black masses in the form of clumps were either vomited or passed by the bowels. I have looked up this passage in Hippocrates[14] and, while there is great temptation to credit the "Father of Medical Literature" with the first trustworthy knowledge of gastric ulcer, I regret to report that his account is not even approximately correct for this disease, but would cover that also of gastric carcinoma and even of secondary gastric hemorrhage, due to cirrhosis of the liver. Some have thought the dietetic treatment which Hippocrates recommended for his *morbus niger* gave evidence that he recognized it to be the disease we know as gastric or peptic ulcer. But even this hope is destroyed by a *critical investigation of the diet of* Hippocrates *for this* purpose. In 1899 Rudolph Bandel, on the incentive of Prof. R. Fleischer, of Erlangen, investigated the writings of Hippocrates for his knowledge on dietetics. It is published in a small pamphlet entitled *"Ansichten u. Ausprüche des Hippokrates über die Ernährung vom Gesunden und Kranden, etc."* (Inaugural dissertation, Erlangen.) In this publication we find nothing to confirm the supposition that the diet of Hippocrates gave evidence of his knowledge of gastric ulcer. The term which Hippocrates gives to the vomited masses in *morbus niger* is *atra bilis* (black bile), which expression maintained itself in medical literature until 1740, when F. R. Hoffmann demonstrated that the seat of *morbus niger* is the stomach. His words are as follows: "Simultaneously with the destruction of the substance of the stomach, the vessels are corroded or broken open, and these open vessels furnish the blood which is expelled by vomiting. We have to assume that the vessels are corroded by sour and acid juices, when a sharp gastric pain precedes the vomiting, and when the vomited bloody masses are black and acid at the same time, make the teeth stand on edge, and irritate the mouth and gullet."

[12] American System of Medicine (edited by Pepper), vol. ii, p. 480.

[13] Vol. ii.

Morgagni (1682-1771), a contemporary of the promi- 'alian anatomists, a pupil of Valsalvas and Alber- l a friend of Lancissi, in his book on "The Seat e Causation of Diseases," does not agree with view of F. R. Hoffmann just expressed, but holds that patients who die of *morbus niger* were suffering from a kind of gangrene of the stomach; that they did not die of loss of blood, but of a kind of poisoning of the blood, which infected the brain. It is interesting to note here that Morgagni described in this work the condition known as "continuous gastric secretion" (gastric succorrhea) occurring in a German nobleman in Bologna, who died later with symptoms of gastric tetany.

The designation *ulcus ventriculi* was first used by the versatile Jena clinician, Johann Peter Frank (1745 to 1821.) It is regrettable that the writings of this scholarly asclepiad are being gradually forgotten, for the modern treatment of gastric ulcer dates from him. The insistance on absolute rest in bed, the application of snow or crushed ice to the stomach, the great regard for dieting (milk and bouillon in small portions), all show exceptional clinical experience. The best that is known on gastric ulcer and gastric diseases in general up to 1850 is presented in the work of William Brinton. Since the descriptions of Cruveilhier, Rokitansky and Virchow, the pathologic conception and the clinical conception of the gastric ulcer have received no notable advance. The further students of this disease, Trousseau, Kussmaul, Ziemssen, Leube, C. A. Ewald, von Mering, Fleiner, Boas, Rosenheim, Riegel, Penzoldt, furnished clinical elaborations, purely.

It might be mentioned before concluding, that the first surgical intervention for gastric ulcer was undertaken in 1881 by Rydygier. For further history of gastric surgery, see Hemmeter.[15]

BLINDNESS AND OCULOMOTOR PALSIES FROM INJURIES NOT INVOLVING THE OPTIC OR OCULOMOTOR NERVES.*

ALVIN A. HUBBELL, M.D., Ph.D.
BUFFALO, N. Y.

That the eye in its visual function and motility is disturbed by causes remote from it, has been known for centuries, and is also a matter of common observation to-day. Among these disturbing causes have been found certain injuries about the face and forehead, which have led to partial or complete loss of vision, usually of one eye, and paralysis, partial or complete, of some of the ocular nerves, these injuries not seeming to involve the particular nerves whose function was impaired or lost. In a large proportion of these cases the injuries have apparently been limited to the fifth nerve, or some of its branches. Hippocrates had noticed this, and it is recorded that he said "the sight is obscured in wounds which are inflicted on the eyebrow or a little higher."[1]

Blindness and ocular palsies following violent injuries of the face and head, and direct injuries of the optic and oculomotor nerves, have recently received careful study and consideration. Berlin[2] read a paper at the Heidelberg Congress, in 1879, in which he reported the statistics of Dr. von Hölder, comprising 124 cases of fracture of the cranium in which postmortems had been made, and in which the fracture, in 79, passed through the orbital vault; and of these 79, 63 involved the walls of the optic canal. He believes that such fractures and direct injuries to the nerves are essential factors in producing the blindness and paralysis often found after head injuries.

Among those who particularly adhere to the same theory are Nettleship,[3] who has studied a large number of gunshot injuries of and about the orbit; Callan,[4] who reported in 1893, 9 cases of orbital traumatism, and who, in a private letter to me a short time ago, said that up to the present time "it has been my fortune to see at least 25 cases of the same type"; Simeon Snell,[5] who has analyzed 18 cases of blindness following injury "chiefly of the anterior part of the head"; Purtscher,[6] who has collected 46 cases of traumatic paralysis of the abducens nerve; and Friedenwald,[7] who continued Purtscher's series by the addition of 11 more belonging to the same class.

[5] Snell: Transactions of the Ophthalmological Society of the United Kingdom, 1897, vol. xvii, p. 81.

I quite agree with the conclusions of these gentlemen that, in most of the cases which they have cited, the blindness or paralysis was due to injury, either direct or indirect, of the affected nerves. It is this class of cases that I would eliminate entirely from this discussion. I wish to reserve only those in which there has been no violent face or head injury, and, so far as can be seen or determined, no direct nor indirect involvement of the disabled nerve itself.

The question naturally arises, Do any such cases exist? To this question both affirmative and negative answers have been given. The negative answers I shall not analyze. On the affirmative side there have been many keen observers, both before the time of the use of the ophthalmoscope and since. The cases cited to sustain the affirmation during the pre-ophthalmoscopic period are by no means valueless, for the ophthalmoscope is not indispensable, always, to determine where an injury has been inflicted or whether an eye has been actually blinded or palsied. We might begin the citation of authorities with Hippocrates and continue it to the present time, and we should find that they include the most learned men and most discriminating observers of the medical world. Let me name a few of those of the past century who have recorded themselves on the affirmative side of this question: Beer,[8] Guthrie,[9] Wardrop,[10] Middlemore,[11] Hocken,[1] Chelius,[12] Lawrence,[13] Hutchinson,[14] de Wecker,[15] Badal,[16] Redard,[17] Norris,[18] Nuel,[19] Noyes,[20] Panas,[21] Chauvel,[22] Spaulding.[23] The list might be greatly extended, but this is sufficient to show the credibility and number of the witnesses. Many individual cases have otherwise been reported, which are said to be due to fracture involving the walls of the optic canal or orbit, but in which there is a possible doubt. For example, Snell,[5] in his report above referred to, included 2 cases, Nos. 2 and 3, of this class; Posey[24] also reported a case of the same kind to the College of Physicians of Philadelphia in 1899; and others have reported similar cases.

I can not reproduce the long list of individual cases which are scattered through medical and ophthalmologic literature, but must refer those interested to the various authorities who have recorded them, some of which I have already named. It seems to me that there is room, in those cases that I have studied, to doubt that there was fracture at the optic foramen or of the orbital walls, or injuries of the disabled nerves, either by laceration, contusion, concussion or extravasation of blood. In most of them the injury has been found to exist in some branch of the fifth or trifacial nerve alone, either the infraorbital, nasal, frontal or supraorbital, and not in the least to involve the optic or motoroculi nerves. That the results described might be indirect seems possible, when it is recalled that there are so many well-authenticated cases recorded, in which paralysis of the intraocular or extraocular muscles and blindness more or less complete have supervened on some disease (not injury) of the trifacial, and particularly of the branches distributed to the teeth. Furthermore, it should be remembered that this great nerve, with its extended distribution, has numerous and important relations, and it is not strange that authors should have concluded that disturbances originating in it may so react on the vasomotor nerves and nerve centers as to interfere with the nutrition of the eye, to check its movements, and even to suspend, partially or completely, temporarily or permanently, so delicate a function as vision.

This reaction has been acknowledged and studied by Brown-Séquard,[25] by Jonathan Hutchinson,[14] by Rondeau,[26] by Hughlings Jackson and by others, and they have designated it as "reflex." Furthermore, it has been claimed that these eye reflexes may originate elsewhere than in the branches of the fifth nerve, and particularly in the genital organs and the intestinal tract. Jonathan Hutchinson[14] says that these reflexes are probably due in many cases "to an influence exerted through the vasomotor nerves only, by which are induced alterations of blood supply to the affected part. It is probable, however, that nutritive alterations may be induced through the nervous system independently of any primary change in the caliber of the blood vessels."

When I recall the anatomy of the bony structures immediately surrounding the optic nerve, and the difficulty of fracturing the canal through which this nerve enters the orbit, and when I stop to think that it is most difficult to implicate any of the other orbital nerves in a fracture that would involve either the sphenoidal fissure or the orbital walls, I am led to question the sufficiency of the fracture theory in the class of cases which I am discussing, and am inclined to accept, at present, for want of a more satisfactory explanation, the reflex theory.

I shall now detail from my own experience a few cases which have appeared to me not to be easily accounted for on the fracture or injury theory.

CASE 1.—Paralysis of the right superior levator palpebræ, and partial paralysis of the right superior rectus muscles following a punctured wound on the right side of the nose, at the inner angle of the eye; recovery.

tient.—J. V. B., male, aged 24, laborer, consulted me on 1, 1903, for inability to raise the right upper lid.

story.—Ten days previously when fishing, a comrade threw hpole toward him, and the small end struck him on the side of the nose in the region of the lachrymal sac, pro- g a puncture of the skin. He was very sure that the pole ot pierce the orbit. Neither the upper eyelid nor the eye- was injured at any point. The eye was dressed and ban- ed over night, and the next morning, on removing the ings he found that he could not raise the upper eyelid.

amination.—At the time of this consultation there was lete ptosis of this eyelid. On raising it with my finger, id there was slight diplopia on turning the eyes upward o the left, but in the primary position he saw singly. In- ion seemed to indicate unrestricted and normal rotation e eye in all directions except upward. The pupil was al in size, and responded normally to light. Vision was al. Iodid of potassium was given internally.

gust 29. The ptosis had nearly disappeared, but he con- d to see double on turning the eyes upward.

tember 12. The function of the levator palpebræ and su- r rectus muscles was fully restored, and the ptosis had en- disappeared.

SE 2.—Paralysis of the left third cranial nerve following from a bicycle.

tient.—P. M., male, aged 23. Referred to me by Dr. le, Nov. 3, 1898.

tory.—On August 27, preceding, he fell from his bicycle truck his head on the pavement. There was no external d nor injury of the eyeball but he was unconscious for l hours. On recovering consciousness there was found total paralysis of the left third cranial nerve, with the ding symptoms of ptosis, divergent strabismus, dilated , etc. For some time afterward there was confusion of ntellect and impairment of memory.

atment.—At the date of consultation the paralysis was improved, and the vision of each eye was five-fifths, ugh both optic discs seemed rather pale. I suggested the al use of iodid of potassium, and the local application ctricity. I have never seen the patient since.

SE 3.—Paralysis of the external rectus muscle of the right llowing a blow over the eye; persisted at the end of four .

ient.—I. B., male, aged 13. Referred to me by Drs. W. reene and E. Clark, Feb. 21, 1898.

tory.—Four years previously he was struck over the eye with a small tin can attached to a string, which ier boy was playing with and swinging. The eyeball was njured. Immediately afterward the right eye began to rge, and has remained convergent up to the present time. as unable to turn the eye outward beyond the median .

amination.—Vision equaled fingers at one to two feet. reacted well to light and was of normal size. Nothing mal could be found in the fundus, even after dilating upil with homatropin. The vision of the left eye equaled fths. No treatment was advised, and the patient was een again.

SE 4.—Paralysis of the right external rectus muscle fol- g a fall and striking on the back of the head; recovery.

ient.—R. M., male, aged 15. Referred to me by Dr. A. lton, July 23, 1903.

story.—About three weeks previously was run down by a le, and in falling struck, as he says, the back of his head. as unconscious for a short time, and afterwards had se- headache. He at once began to see double, and the right as found to be convergent.

amination.—At the time of consultation there was al- complete paralysis of the external rectus muscle of the eye. The vision was normal in each eye, and so was each s. The eyeball had not been injured, and there was no nce of intracranial hemorrhage.

tment.—I advised iodid of potassium to be given internally, and the covering of one eye until the paralysis disappeared.

August 27. Paralysis was much improved. Advised the continuance of the same treatment.

Later, I was informed that the case had entirely recovered.

CASE 5.—Paralysis of the external rectus muscle of the right eye following a slight bruise over the eye; recovery.

Patient.—H. B., male, aged 50, railroad employe, consulted me on March 27, 1897.

History.—He fell out of the door of a baggage car a few days previously, and struck his head against an object, leaving a slight bruise over the right eye near the hair of the scalp. There was no loss of consciousness and no dizziness. Immediately after the injury he began to see double.

Examination.—On examination I found that the right external rectus muscle was partially paralyzed, leaving a pronounced convergent strabismus. Fundi of both eyes were normal.

Treatment.—After correcting a slight hypermetropia the vision of each eye equaled five-fifths. Strychnia was given internally, and the paralysis disappeared after a few weeks.

CASE 6.—Paralysis of the external rectus muscle of the right eye, following an operation in the nose; recovery.

Patient.—E. H., woman, aged 23. On Jan. 24, 1898, I was called in consultation to see the patient by Dr. Horace Clark, and obtained the following history:

History.—On January 17, the physician removed the right middle turbinated bone, and then proceeding some distance backward and upward, undertook to remove further bony obstruction with a gouge by making light taps on it with a mallet. This did not seem sufficient, so he gave it a harder tap, when she at once complained of severe pain on the right side of the head and forehead, which continued for about an hour. Immediately after the onset of the pain she began to see double, and the physician noted that the right eye was convergent from paralysis of the external rectus muscle. Two days afterward a distinct ecchymosis was observed in the right lower lid, and there was also a slight ecchymosis of the conjunctiva of the eyeball on the lower and outer side. It was not possible, the physician said, for the chisel to have pierced the floor or apex of the orbit at any point. Dr. Lucien Howe had also seen the case.

Examination.—Examination showed that the vision of the eye seemed to be normal, although test letters were not used. There was still some ecchymosis of the lid and conjunctiva, but otherwise the structural appearances of the eye were normal. The ophthalmoscope showed an unusual redness of the optic disc, which perhaps was normal, as the same appearance was present in the other eye. I expressed the opinion that the case was one of reflex paralysis of the external rectus muscle, and gave a favorable prognosis.

February 2.—On examination at my office, the paralysis was somewhat improved. There was refractive error in each eye, and without correction vision equaled five-sixths each. With correction it was five-fifths each. With the ophthalmoscope there was seen the same unusual redness of both optic discs. Ordered the correcting glasses.

April 9.—The right external rectus muscle had entirely recovered its normal strength, and the convergence had disappeared.

CASE 7.—Blindness following cut over the left eye, extending through the eyebrow and into the base of the orbit.

Patient.—C. C. H., male, aged 23, musician, consulted me on Nov. 17, 1896.

History.—Three days before, when in a house of ill-fame, he was attacked by one of the girls and struck with a case-knife, inflicting a wound over the left eye which extended through the eyebrow from above, downward and outward into the orbit. He was taken to the Emergency Hospital on Michigan street, and attended by Dr. Francis J. Carr, who closed the wound with sutures and on the third day sent him to me.

Examination.—I found some swelling of the eyelid and of the orbital tissues. The pupil was dilated, and vision in this eye was totally lost, even to the strongest light. There was no injury of the eyeball. The ophthalmoscope showed that the refractive media were clear, and the fundus normal.

Treatment and Result.—The case was treated with cold applications over the parts, and medium-sized doses of iodid of potassium were given internally.

On December 1, the swelling had entirely disappeared, there was some conjunctival and lid ecchymosis, and the movements of the eye were normal, except in the outward direction. There was no vision, and the ophthalmoscopic appearances were the same as before.

On December 21 the movements of the eye were normal except outward, and this was improved. Pupil was a little dilated when the right eye was covered, but responded consensually to light acting on the other eye. The ophthalmoscope showed that the optic disc was becoming a little pale. The potassium, internally, was continued.

February 1. The optic disc had continued to grow pale and the retinal vessels were smaller than normal. The external rectus muscle was still semi-paralyzed, but the patient was able to turn the eye outward considerably beyond the median plane. Vision remained *nil.*

The vision of the other eye was normal.

CASE 8.—Blindness of right eye following a fall.

Patient.—F. M., male, aged 11.

History.—On Nov. 1, 1901, he was riding on horseback, when the horse stumbled and he was thrown to the ground, striking his head on the right side and cutting the skin over the right eyebrow. There was no bleeding from the nose or ears. He was dazed for ten or fifteen minutes, after which he was taken to Dr. G. H. Grant, who dressed the wound and applied a bandage so as to cover both the wound and that eye. The dressing was kept on for a week or ten days. On removing it he found that he could barely distinguish light from darkness with that eye. He had severe headaches for several days after the injury.

Examination.—On November 26, Dr. Grant brought him to me, when the examination showed that the pupil did not respond to light, except in harmony with the light reflex of the other eye. With the ophthalmoscope the optic disc of that eye had a slightly waxy white color, but the retinal vessels were normal in size, and there were no lesions elsewhere in the fundus. The vision was totally lost, even to the strongest light. The vision of the left eye was five-fifths. Potassium iodid was ordered to be given internally, but the prognosis as to vision was unfavorable.

Result.—The optic disc of the right eye gradually passed into complete atrophy, and at the present time the eye is totally blind.

CASE 9.—Injury above and below the left eye followed by blindness after three or four days.

Patient.—L. B., male, aged 21.

History.—On May 26, 1900, while riding on his bicycle, he collided with another bicyclist and fell and struck his head in such a manner as to bruise his nose and face and to produce a cut through the outer part of the left eyebrow. He was unconscious for about an hour, and delirious for about two hours more. He had profuse nose bleed after the fall. Much swelling over and around the eye followed, and for several days it was with much difficulty that the lids could be opened. He thought that on the day following the injury he could see a little, but in three or four days the vision was entirely lost. He also said that there was a sense of numbness in the left side of his face and upper jaw, including the teeth on that side. He was treated by Dr. Borden in consultation with Dr. Lake of Gowanda, N. Y., who referred him to me.

Examination.—On June 11, when I saw the case, I found the wound of the eyebrow healed. There was no swelling of the tissues of the orbit, but there was a small conjunctival chemosis on the outer side of the eye. The movements of the eyeball were normal and unrestricted in all directions. The pupil reacted consentaneously with the other, but did not respond to light when it alone was exposed, and was dilated when the right eye was covered. There was entire absence of perception of the strongest light. The ophthalmoscope showed nothing abnormal, except, perhaps, that the retinal veins were a little distended. The numbness in the left side of face and jaw was still perceptible.

Treatment.—Prognosis, so far as vision was concerned, was pronounced unfavorable. Advised the continued use of iodid of potassium and strychnia internally.

July 3. No vision of the left eye, and optic disc of that eye was pale and waxy in appearance. Continued treatment as before for a few weeks.

April 29, 1903. Optic disc of left eye had become atrophic and blindness continued. The vision of the other eye was normal.

CASE 10.—Immediate blindness of left eye following an injury at the base of the orbit, at the lower and inner portion.

Patient.—T. K., male, aged 36, occupation, foreman in a metallic bedstead manufactory; was brought to me by Dr. Charles P. Chapin of Buffalo on Aug. 30, 1903.

History.—The right eye had been blind for three years with cataract, caused by being struck with a piece of iron. Two days previously (August 28), while working in the manufactory, he bent over to reach for something and struck a projecting wire, the end piercing the lower lid of the left eye sidewise from without, inward, and slightly, but not directly, backward. The skin was torn for perhaps a third of an inch at a point just above the lower margin of the orbit, and a little beyond the center of the lid toward the nose. Patient insisted that the wire did not penetrate more than one-half inch, if it did to that extent, even. Immediately after the injury he found himself totally blind in the left eye, and, having been blind from cataract in the other eye before this, the outside world was now entirely closed to him so far as his vision was concerned. There was not the slightest disturbance of consciousness or equilibrium. He was taken to a physician nearby who closed the external wound with a suture, and declared to him that the eyeball was not injured, and that he thought that the vision would return after a few days.

Examination.—When first examined by me, August 30, there was no swelling of the lids, no effusion nor swelling of the cellular tissue of the orbit at any point. There was, however, some ecchymosis of the lower lid, and a very small ecchymosis of the conjunctiva of the lower part of the eyeball. I examined very carefully for evidence of a wound of the eyeball, but I did not find the slightest. Neither was there any evidence of deep penetration of the orbit. Patient said that the hemorrhage from the wound was very slight, and that there was no bleeding from the nose. There had been no pain since the injury was inflicted. Further examination of the eye showed that the pupil was dilated when the other eye was covered, and that it did not respond to light. It did, however, contract consensually on exposure of the right eye to light. The refractive media were absolutely clear, and the fundus was distinctly seen. Not the slightest change in the eyeground could be found, unless it was that the retinal veins were a little more distended than normally, alhough this, even, was questionable. There was not the faintest perception of the strongest light. I predicted permanent blindness of this eye with subsequent atrophy of the optic nerve.

Treatment.—I at once took steps to restore the vision of the right eye which had been injured three years ago by being struck with a chip of steel. Examination of it revealed the presence of a small piece of iron lodged in the iris on the nasal side about half way between the pupillary and peripheral margins. The lens was fully opaque and the iris was adherent to it at the point of injury. Pupil responded fairly well to light, and vision equaled good perception of light throughout the visual field. The presence of the steel was shown both by inspection and by its being attracted by the electro-magnet. On September 1, I made an incision through the cornea at the inner margin and loosened the steel with a Sweet electro-magnet, and withdrew it from the anterior chamber with a small iris forceps. The eye recovered rapidly from the operation, and on September 15 I extracted the cataract without iridectomy. The recovery from this operation was also rapid, but the capsule was left in a thickened and opaque condition. On October 12, I lit the capsule with two needles, leaving a good central pening. On October 26, with + 14.00 D.S., vision equaled ve-sixths and with + 3.00 D.S. added, vision equaled Jaeger o. 1 at fourteen inches. Glasses were ordered accordingly, nd he resumed his occupation.

At the present time the vision of the left eye remains to-lly lost, and the optic nerve has become quite atrophic. ith the right eye he sees as before.

Of these 10 cases, 6 are paralysis of the extraocular uscles, without any evidence of the muscles themselves r their nerve supply being directly injured, either by contusion, compression or hemorrhage, and 4 are ses of unilateral blindness which vary somewhat in e nature of the injury. In Cases 7 and 10 it seems npossible to account for the blindness, on the assumption that the optic nerve was injured directly, or by ompression through fracture of the optic foramen. n the one it does not seem to me that the knife could ave penetrated to the apex of the orbit, and cut or ruised the optic nerve without seriously injuring, also, ther important orbital structures, or that the sphenoid one could have been fractured at the optic foramen rough impact on the vault of the orbit. In the other se we have the positive statement of the patient that wire did not penetrate deeply into the orbit, and e symptoms following the injury, so far as the orbital tructures are concerned, are opposed to such a supposition. In the other 2 cases the injuries were more violent, and while I can not see how they could cause a racture at the optic foramen, yet I am not prepared say that such an occurrence was not possible. My resent opinion, however, is that none of these ten cases clearly explainable on the fracture or direct injury eory. Are they not all reflex?

DISCUSSION.

Dr. S. D. Risley, Philadephia, said that he is not quite willing to accept the theory of reflex origin of the blindness in the ses mentioned. He has never been able to grasp a satisfying comprehension of the reflex origin of a disease; particurly of one so serious as to cause blindness, though there are rtain clinical facts which seem to bear out this theory. The te Dr. Flagg *several years ago published in the Dental Cosos* a report of a case of total blindness which was brought him for inspection of the teeth. Dr. Flagg found that placıg a piece of ice on a certain tooth demonstrated excessive nsibility to cold in that tooth. Extraction of the tooth was llowed by almost immediate restoration in sight. The upils, which had been widely dilated, contracted and vision turned to normal. A curious deposit was found in the pulp vity of the tooth. Pressure on the dental branch of the rve seemed to have this marked effect on vision. *Dr. Risley* entioned the case of a man who had a high degree of mixed stigmatism and who had worn glasses for several years with uch comfort, but finally came back with a great deal of discomfort. On investigating the mouth Dr. Risley found that e premolar was double and that the first tooth had not been rown off. After extraction of the deciduous teeth there was omplete relief from headache and from impaired vision. Dr. isley has seen eight cases, six of which were totally blind in e eye involved, one partially blind in both eyes and in the ther paralysis of the third pair of nerves, the man having een injured by being thrown from his buggy by a train. In is case the eyelid was paralyzed afterward and with no inry to the nerve. A *carter was thrown from his cart*, striking on the left superior orbital rim and went blind in six eeks from atrophy of the optic nerve on the side of the inry. A small child fell and struck the *inferior orbital* rim gainst the end of a stick she was carrying in her hand, aparently not causing any very serious injury. A few days ter she complained of impaired sight and went blind with atrophy of the optic nerve. Another case, a man, was struck on the top of the head *anteriorly with a piece of scantling* and in a few days noticed impairment of sight and recovered finally with only 1/10 vision. These were very interesting cases to Dr. Risley, but so far from regarding the blindness of reflex origin he has been inclined to think that the optic nerve itself had been injured, the force of the blow being conducted along the walls of the orbit and pressing the nerve, whether there had been a fracture of the foramen or not; or in the case of paralysis of the oculomotor that the nerve had been *injured in the sphenoidal fissure*. While on a visit in the west Dr. Risley saw a case of a farmer who was thrown from his horse-rake, sustaining a fracture of the temporal wall of the left orbit. There was profuse intraocular hemorrhage and total blindness ensued with optic atrophy in the injured eye.

Dr. G. E. de Schweinitz, Philadelphia, regretted that Dr. Hubbell should lend the weight of his authority to a theory which rests on so slight a foundation as that of reflex blindness. Dr. de Schweinitz said that while it is not always possible to state with accuracy the underlying pathologic conditions which cause loss of sight under the circumstances which Dr. Hubbell has detailed, and while there is often no clinical evidence, *at first, at least, of injury to the optic nerve*, it seems to him that most of these cases can be explained without an appeal to a reflex theory. Certainly some are due to hemorrhage *in the sheath of the optic nerve*, and recent investigations have shown that after comparatively slight blows on the head there may be fracture of the base of the skull, or a fissure running into the optic canal, which of itself would cause to be thrown out much inflammatory *material* and so make pressure on the nerve, or be the cause of a hemorrhage *into the optic nerve sheath*. Dr. de Schweinitz considers that some of these cases may be due to an *infection*, perhaps, of the optic nerve sheath, precisely as an infection may be caused in the pleura by the removal of a stitch, or from a wound on or above the brow. Finally, if there should be a sustained vasomotor alteration affecting the retinal circulation, such as probably takes place with certain toxic agents in the system, the *ganglion* cells of the retina are starved and degenerate and cause an ascending atrophy of the optic nerve.

Dr. Alvin A. Hubbell said that he does not think that Dr. de Schweinitz has explained away the reflex theory. He should be glad to accept the fracture or injury theory, if it *seemed sufficient*, but in many cases it does not. Moreover, the reflex theory appeals to him, as there are cases of blindness and oculomotor paralysis in which there has been no injury of any kind, and which were the result, apparently, of disease remote from the eye itself. Many such can be gathered from both American and European authorities. Dr. Hubbell confessed that the reflex theory has its difficulties, and he desires further enlightenment. *After eliminating cases of* undoubted traumatic involvement of the ocular nerves whose *function is impaired or lost, there seems to remain a residuum* of cases in which the injury *does not reach to or implicate* them, and that belong to that class heretofore known as reflex.

CONTRACTION OF THE VISUAL FIELD;

A SYMPTOM OF ANESTHESIA OF THE RETINA IN CHILDREN.*

L. WEBSTER FOX, A.M., M.D.
PHILADELPHIA.

The term retinal anesthesia is usually employed to designate a rather vague condition in which the function of the retina is temporarily suspended or its sensibility greatly diminished. In many text-books it is included in retinal diseases only for consistency's sake and to describe a possibility of the occurrence of such a condition. But from the descriptions usually given it would seem that authors had never encountered the affection as a purely independent disease having definite symptoms, treatment and prognosis. It is my purpose in this paper to present the features of this condition as I have met with it and to substantiate my statements with brief histories of my cases. This retinal anesthesia, in my experience, is characterized by a reduction in the acuity of vision and marked contraction of the visual fields, with no reversal in the color fields. There are no other symptoms, and the eyeground is normal in every respect. The affection is by no means infrequent and is usually observed in children from six to fourteen years of age of both sexes, being most common in children of the better class of people. The acuity of vision is rather suddenly diminished, and this diminution is first manifested by the child becoming awkward and by stumbling over objects not in the direct line of vision. An inability to read except in very strong light makes its appearance in a very short time, and soon distant vision also becomes reduced. At this stage of the affection the ophthalmologist is usually consulted and a careful examination of the visual field will reveal marked contraction, varying from 30 to 55 degrees in both the vertical and horizontal meridians, and a reduction of vision to one-fifth normal or less. The color fields are contracted proportionately and maintain their relation to each other. Visual scotomata are absent. The ophthalmoscopic examination reveals nothing abnormal. The pupils are semi-dilated and somewhat inactive. The patients are usually in good health and complain of no symptoms other than the great loss of vision.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

The treatment which I employ in these cases is the daily application of a weak constant electric current, one or two milliamperes "voltaic alternatives." The negative pole should be placed over the eyeball and the positive pole over the opposite temple or nape of the neck. The sitting should be of about ten minutes' duration. The fields should be taken daily during the treatment and marked improvement will be observed within a few days. Recovery is prompt. As in other ocular conditions, the state of the refraction should be ascertained, but any error present should not be corrected until after a thorough course of electric treatment. The refraction should not be considered as an essential portion of the treatment for reasons I shall give later. The total number of cases under observation have been twenty-four.

CASE 1.—A. B., girl, aged 9 years, was brought to me in December, 1887, with a history of general awkwardness and diminution of vision, which in examination by test letters was found to be R. E. 20/70, L. E. 20/50 (one letter). The visual field was shown by the perimeter to be markedly contracted. The eyeground was normal with the possible exception that the veins were dilated and tortuous. The refraction was examined and Sph. plus 0.25 was found for each eye; glasses were not prescribed. The patient was referred to Dr. G. G. Faught for electrical treatment as described, and after five applications the visual fields and vision were restored to normal. The patient was then discharged. She was again seen by me in November, 1894, but had had no recurrence up to that date.

CASE 2.—F. H., boy, aged 10 years, consulted me in February, 1894, with a similar history, and the additional symptom of headache. Examination of the visual fields also showed marked contraction to 10 degrees in all meridians. Hyperopic astigmatism was detected at this time (Cyl. plus 0.50, ax. 90), confirmed by retinoscopy and trial lenses. The electrical treatment was employed four times, and nine days after the first visit to me the fields were found normal. The astigmatic correction was refused at this time. When seen in April, 1904, he stated that he had had no recurrence. Examination of the fundus showed the optic nerve to be red and excessive pigment in the choroidal coat. The ametropia under atropin, and confirmed by retinoscopy at this time, was R. E. Sph. —3.00, L. E. Sph. —1.00, which were prescribed, a change from hyperopic astigmatism cyl. plus 0.50 ax. 90 in both eyes to present condition of myopia which had developed during the past ten years.

CASE 3.—H. P., a boy, aged 10 years, came under my observation August, 1895, with visual disturbances and slight headache. The fields were found contracted irregularly to 10 to 20 degrees. Mixed astigmatism was detected and corrected. Sph. plus 0.25, cyl. —0.50, ax. 180; L. E., Sph. plus 0.37, cyl. —0.50, ax. 180. After several applications the field became normal in extent and the patient was discharged. In February, 1897, the patient again consulted me, and a slight contraction of the lower field was detected. No change required in the glasses. In January, 1904, I again saw the patient, at which date the fields were normal, and no change required in the glasses.

CASE 4.—C. N., female, aged 12 years, was seen by me in January, 1896, with the complaint of failing vision, which by means of test letters was shown to be 20/100 in both eyes. The correcting lenses (B. E. Sph. plus 0.50) served to increase the vision to 20/50. The fields were found to be contracted to 10 degrees in all meridians, but were restored promptly to normal after eight electrical treatments, combined with rest. Vision, both eyes, 20/20. In April, 1899, there was a slight recurrence, possibly owing to her greatly weakened condition. The patient died of pernicious anemia in November, 1896.

CASE 5.—H. C., girl, aged 10 years, came under my professional care in October, 1897, with vision R. E. 5/100, L. E. 20/200, and fields contracted to 20 degrees in the principal meridians. There was a history of a blow on the head. As there was no change in the color of the optic nerves, I did not think that the blow caused any change in the vision or fields. The electrical treatment was instituted, and within four weeks the left field was normal, but the right was still contracted. Three months later, however, the right field was normal. Myopia (Sph. —1.00) was present. In March, 1904, a recurrence occurred, due, in all probability, to excessive study. The refraction was examined and high myopic astigmatism detected and corrected (R. E., Sph. —4.25, cyl. —0.50, ax. 5; L. E., Sph. —4.50, cyl. —1.25, ax. 180).

CASE 6.—H. S., a girl, aged 11 years, was brought to me Feb. 25, 1899, with failing vision (20/200), both eyes, and contracted fields to 15 degrees without obvious cause. Lenses cyl. —0.50, ax. 180, both eyes, failed to improve vision more than 20/70. After five electrical treatments the fields became normal, and concave (cyl. —0.50, axis 180) cylindrical lenses were accepted, with vision restored to 20/20. No recurrence.

CASE 7.—J. G., a boy, aged 10 years, consulted me in November, 1899, with failing vision, 20/200, which lenses failed to improve. There were no structural changes to account for this loss of visual acuity. The perimeter demonstrated contraction of the fields to 30 degrees. After eight electric treatments the fields became normal and visual acuity increased to 20/20. There was no recurrence to my knowledge.

CASE 8.—J. J. D., boy, aged 9 years, complained of failing vision Feb. 21, 1899. The fields were found contracted to 30 degress, vision 20/100, and the optic nerves pale. Glasses afforded no improvement. The electrical treatment was employed twice, when the visual fields and vision were found to be normal.

CASE 9.—B. H., girl, aged 11 years, was brought to me Oct. 12, 1900, because of loss of vision. Examination by means of test letters showed the vision to be 20/70 in the right eye and 20/100 in the left eye. The fields were contracted to 10 degrees in the vertical and 20 degrees in the horizontal meridian. There was a very small degree of simple hyperopia. Seven electric applications restored the fields to normal, and vision 20/20.

CASE 10.—S. P., a boy, aged 8 years, complained of failing vision Oct. 21, 1898. No other subjective symptoms were present. The fields were found contracted to 20 degrees in both meridians and vision 20/100. Slight error of refraction was detected, but lenses afforded no improvement. Restoration of fields and vision occurred after nine electric applications.

Case 15.—Indian girl, aged 12 years, complained of failing sion, November, 1902. R. E. 20/100, L. E. 20/40. A slight ror of refraction (Sph. plus 0.25) was present, but glasses ere not worn. Fields contracted to, R. E. 30 degrees, L. E. 40 grees, in both meridians. Improvement followed seven applitions of electricity. She had all the characteristics of her ce, being a pure-blooded Sioux, strong and robust.

This is the only case among the red race I have ever und, having examined thirty-five hundred children.

The other thirteen cases were similar in character— e same contracted fields, with loss of vision; good relts obtained by the use of electricity. Two cases are der treatment at the present time.

In presenting these cases, the points to which I wish lay great emphasis are the occurrence of contracted sual fields in children between the ages of 8 and 16 ars having unaccountable diminution of vision and e prompt restoration to normal vision and enlargeent of the visual fields, after the use of the constant ectric current (voltaic alternatives). These observans I believe to be original with myself. A few other lmologists have closely approached them, how- W. F. Southard[1] observed in 1896 a case occura delicate woman, 26 years of age, in which e was a history of headache and diplopia for a riod of three months, followed by sudden blindness. fields were contracted and there were hemiopia and te scotoma of fixation in the right eye. Examn of the refraction revealed the following error: . C—1.75 ax. 180 L. E. C.—1.25 ax. 180. The earing of correcting lenses increased the vision. Improvement also occurred under the influence of rest, but recurrences of the blindness were common. Hysteria s excluded as an etiologic factor. P. B. Wing of acoma[2] observed a case in a robust, well-nourished y of 8 years, of failing vision, which lenses failed to lieve. It became progressively worse, and the fields came contracted. The condition was attributed to ffee, which the patient consumed at the rate of six to ght cups daily. One month after the institution of oper treatment vision was normal and the fields full.

The cases I have described I believe to belong to the ass of functional disorders of the retina termed retinal esthesia, as there seems undoubtedly to be a temporary spension of sensibility in that structure. Apparently seems to be a condition of fatigue due to overwork the time of life when the sensory elements are least epared for any strain. It will be recalled that these ses occurred between the ages of 8 and 16 years, and ostly in robust individuals, and not limited to the te race alone, as I have mentioned one case where is condition was found in a robust Indian girl.

Hysteria, however, I think, may readily be excluded om the etiology. The patients usually possessed no ncomitant signs, the color fields were not inverted, r were there any of the ordinary ocular symptoms of steria. Eyestrain has been suggested as a possible use, but it will be remembered that in only three were ere any of the ordinary asthenopic manifestations. hile errors of refraction were corrected in most cases, ere were seven instances in which the current was ed alone, and the response was prompt as usual and ere were no recurrences. Frequently the correction cepted during the affection was rejected when the elds and vision were restored. The only case in which ere was a complete return of the condition was one ving myopia, which was carefully corrected during the first attack, but required a change of lenses at the time of the subsequent attack; as this was a case of progressive myopia, the change in the glasses was due to this alone. In one case vision was normal and the fields contracted. Glasses were not called for, and recovery was prompt by the use of electricity.

The manner in which the electric current brings about its beneficial effects in these cases is not clear. It has been suggested to me that the constant current redirects the proper nerve impulses to the retina, and at the same time it would seem that these treatments served to increase the blood supply, and consequently the nutrition of the affected structure. In all of the cases mentioned, general rest from study was of value, showing that in large part the affection was nutritional in origin, despite the fact that the patients were apparently well nourished and healthy.

It gives me great pleasure to quote Dr. G. Granville Faught's experiences in the evolution of this treatment:

"Twenty years ago electrotherapeutics was mainly a matter of empiricism, and in no department was it more so than in that of the eye. Erb of Leipzig, in a publication dated 1883, says: 'We are thus compelled to acknowledge the deficiency of the theoretical basis of our electrotherapeutic knowledge; now, as formerly, it must be studied on an empirical basis.'"

As to the eye, Erbe says: "To my regret I must admit that very little is known with regard to the pathologic relations of the electrical irritability of the retina and optic nerve." In the use of the electric current at this time, Erb particularly advises that "sudden interruptions or reversal of the current should be avoided"; and, again, "do not make any interruptions or changes of polarity." Strümpell (Vickery, Knapp, Shattuck), writing in 1887, follows the teaching of Erb, and on the treatment of ocular paralysis says: "Of other remedies galvanic treatment gives the speediest relief. We pass weak currents transversely through the temples, or, what is usually better, put the anode on the back of the head and apply the labile kathode to the closed eye. Great caution, weak currents, and the avoidance of any great variations in the current are, of course, necessary; the current should not be too strong, and there should be no abrupt changes in it."

It was at this time and under these conditions that Dr. Fox and myself began the study of electrotherapeutics in relation to the eye. Among many other cases, my attention was early directed by Dr. Fox to those of retinal anesthesia, and in connection with these I conducted a considerable experimenture. In many cases a definite result was obtained by the ordinary application of the galvanic current, but not sufficiently speedy and certain to be satisfactory, so that I was finally led to consider the subject of Volta's alternatives. From the days of Volta it has been a well-determined fact that "if the current has been closed for some time in one direction, the irritability of the nerve is increased to opening in the same direction or closure in the opposite." However well known, no use was made of this in the matter of therapeutics until I took it up in connection with the treatment of retinal anesthesia. I was sure that what was eminently true as to motor phenomena would prove equally true in connection with sensory conditions, and my belief has been abundantly confirmed. After several years of experimenture, I affected a method of therapy which I designated as "Voltaic Alternatives" (Houston, Dictionary, "a term used in medical electricity to indicate sudden reversals in

---

1. Pacific Med. Journal, May, 1902.
2. Annals of Ophthal., April, 1903.

the polarity of the electrodes of a Voltaic battery"), and I devised a "pole-changing handle."[3]

I regret to state that little or nothing has been done since then in this matter of voltaic alternatives. Dr. Fox and myself have had eminent success in numerous lesions of the eye, vitreous opacities, retinitis-pigmentosa, chorio-retinitis and choroiditis, by this method, and it is to be hoped that this article will lead others to follow in our footsteps.

In ordinary usage I employ a current of 2 milliamperes, and reverse it at intervals of two seconds, continuing the treatment to a period of ten minutes.

DISCUSSION.

DR. WALTER L. PYLE, Philadelphia, said that he believes this affection to be a reflex inhibitory paresis of the peripheral visual cells in the retina, acting in the same manner as a reflex paralysis of the orbicularis in certain cases of uncorrected or improperly corrected ametropic eye-strain. He has often noticed the deficient vision without sufficient ophthalmoscopic changes in ametropic young persons, particularly school girls, and he has seen speedy restoration of full visual acuity by the simple use of the ametropic correction. He has never measured the visual fields in these cases, and thinks that full credit should be given to Dr. Fox for calling attention to the perimetric findings. Dr. Pyle thinks that overwork is undoubtedly the main factor. In younger persons, malnutrition is probably an important cause. It is often due to ametropic eye-strain, and after proper refraction most of the patients recover without the application of electricity. The constant current probably overcomes the reflex inhibitory influence and undoubtedly greatly hastens the recovery of visual acuity. However, the careful correction of even very low degrees of refractive error is of great importance. Small amounts of astigmatism, particularly at oblique axes, should be looked for.

DR. E. E. HOLT, Portland, Me., stated that he has observed several of these cases. On taking the field of vision it is found to be markedly contracted. His experience has coincided with that of Dr. Fox, that electricity restores normal vision, and he has not found that they relapsed. The condition, he thinks, is brought about by overwork.

DR. G. E. DE SCHWEINITZ, Philadelphia, asked what is the distinction between the cases reported by Dr. Fox and those which have been described many times by various writers under the names of retinal asthenopia, retinal anesthesia and nervous weakness of sight, the inappropriateness of which he recognizes. These conditions occur in young subjects, usually school girls near the age of puberty, who present reduction of acuity of vision unimproved by optical therapeutics, contraction of the visual field, and normal ophthalmoscopic appearances. They recover under proper hygienic treatment. Dr. de Schweinitz agreed with Dr. Fox that they do not in the least represent hysterical manifestations because the ordinary signs of the hysteric field are not present, that is, permanent contraction and frequent inversion of the color lines. They do present, however, an unstable contraction of the visual field, and sometimes the so-called oscillating field. They seem dependent on some instability of the whole nervous mechanism.

DR. L. WEBSTER FOX said that there is a suspension of function in the retina and that it is not a hysteric one, he is sure. The contraction of the color fields corresponds to the field of vision at the time. If the normal field is down to 10, then all colors are visible up to that point. There has seemed to be no reversion of the fields, and therein it differs from the other class of cases (hysteric). In 1884 it was discovered that by changing the current rapidly in a motor nerve function could be restored where otherwise it could not be done. Dr. Faught was the first to adopt the idea in the treatment of a sensory nerve, and it is the rapid alteration that seems to bring about the result. He has invented a little handle by which this can be done very nicely. It is marvelous what one or two applications can do in some of these cases.

AN EXACT AND SECURE TUCKING OPERATION FOR ADVANCING AN OCULAR MUSCLE.*

FRANK C. TODD, M.D.
Professor of Ophthalmology and Otology, University of Minnesota.
MINNEAPOLIS.

The fact that many advancement operations have been devised is evidence that there is dissatisfaction with the various methods. Many of these operations are very similar, and if the different descriptions are placed side by side it will be found that they could be arranged in such a manner as to show only slight variations, and yet, like the colors of the spectrum which merge from one into another, the two extremes will be found to be very different and many new principles may be detected which have gradually been introduced. The evolution is slow but upward, those new principles which have proven of value remaining while those not practical and false have been discarded.

I desire to demonstrate† my method of performing this operation, but before doing so wish to call attention to other operations of like character, i. e., muscle-folding operations, in order that those who have done original work in this field may be given due credit.

HISTORY OF FOLDING OPERATIONS.

Knapp[1] gives credit to J. F. Noyes[2] of Detroit for having been first to describe an operation for shortening of the muscle by folding (1874). "The tendon is divided near its insertion, and the distal end brought forward under the proximal end, lapped, and sutured. At the same time a portion of the tendon may be or may not be cut off. The point of insertion of the tendon is not changed in this method. The folding of a piece has, of course, the same effect as if so much of the tendon had been excised." This operation, while having enough points of resemblance to be included in a description of the evolution of shortening operations, is not a tucking operation, as the tendon was cut.

De Wecker[3] performed a folding of the capsule and tendon, which was described in 1885. He makes a vertical incision in the conjunctiva over the tendon and undermines the conjunctiva toward and around the cornea as far as the vertical meridian, opens Tenon's capsule at the lower border of the tendon, passes a hook under the tendon, incising the capsule where it emerges on the upper side. He then inserts one suture into the episcleral tissue above the cornea, and the other end through the opening in the capsule into the upper edge of the muscle on through the conjunctiva, and then ties this suture. A like suture is passed through the lower edge of the muscle and the episcleral tissue below the cornea.

Knapp[4] did a similar operation, which was described in 1886 as an improvement on de Wecker's. Knapp's modification consists in the use of one or two additional sutures inserted in a similar manner between these two tures. In both of these operations the tendon and psule were folded on themselves and not divided.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

† The operation was demonstrated at the meeting on a large manikin.

[4] H. Knapp: Advancement of Tenon's Capsule. Transactions of the American Ophthalmological Society, July, 1886.

In 1892 Lagleize[5] of Buenos Ayres described a fold-g operation *in which the tendon is folded on itself*, or ther the muscle is folded on the tendon. In his opera-on a piece of conjunctiva is excised over the tendon, a ook is passed under the tendon near its insertion and nother under the muscle. One needle of a doubly-ed suture is passed through the muscle and con-nctiva from within outward near the posterior hook, millimeter from the upper border of the muscle, hile the other needle is passed in the same manner one illimeter from the lower border. Both needles are carried under the conjunctiva to the cornea, into e episcleral tissue, and the threads tied, causing the uscle to be folded on the tendon. The tighter the reads are pulled the greater the effect. The tendon in is operation is not severed.

Savage[6] published, in 1893, the description of his peration. *The conjunctiva, and then Tenon's capsule,* cut just below the lower border of the muscle (when perating on a lateral muscle). Through this hole two abismus hooks are placed; one hook is pushed forward the insertion of the tendon and the other backward ward the belly of the muscle. One needle of a doubly-rmed silk suture is passed through the cut beneath the don and forced through the tendon near the upper order, close to the scleral attachment. The second dle is passed through the cut beneath the muscle lly, through the upper border of the muscle, then rough the capsule and conjunctiva; the same needle is sed back through conjunctiva, capsule and muscle di-ly under the last point pierced and near the lower order of the muscle, then passed forward under the uscle, to again emerge through the tendon at its inser-*ion just under the point pierced by the first needle.* Both hooks having been removed, the two ends of the suture are tied over the Price suture plate, thus producing the fold. The distinctive feature of this operation, which was not practiced in any operation described previous, is the folding of the tendon on itself by introducing sutures only in the muscle and tendon, and not into the sclera, and the use of the Price suture plate to prevent cutting of sutures.

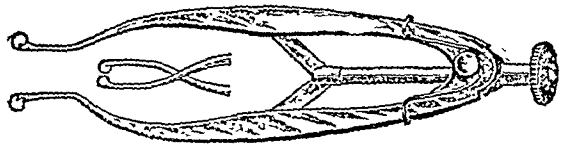

Fig. 1.—Author's tendon tucker.

Tenney of Boston devised in 1894 an instrument to aid in the performance of Savage's operation.

Grandclément's operation,[7] described in 1893, is as follows: With a pair of fixation forceps he raises a vertical fold through which he passes the needles of a doubly-armed suture (through the conjunctiva capsule and tendon), making a loop.

Valk,[8] working independently, described his method in 1895. After dissecting Tenon's capsule, he lifts the tendon with his pair of twin strabismus hooks, carries a catgut suture through the tendon from without inward, close to the sclerotic, passes backward under the muscle through the muscle from within outward; crossing the *muscle, the suture* is reinserted from without inward through the muscle back to a point above or below the place at which the suture was first inserted. Thus the suture is placed like that of Savage. When tied, the tuck is taken. Valk was the first to suggest the use of an absorbable suture.

Greene[9] described a tendon-tucker and his method of tucking in 1899. He says: "I have tried several expedients to get rid of the objectionable features of the operation which I have already mentioned, when, several years ago, I conceived the idea of taking a tuck in the tendon, which I did several times by the use of sutures. I thought it a new idea, but on searching the literature on the subject I found it had been done before by J. F. Noyes of Detroit, in 1874, and Lagleize, in 1892." Greene objected to the use of the conjunctival sutures, and, after producing the tuck, introduced one catgut suture, binding the middle of three layers of tendon; thus he followed the practice of Savage and Valk in introducing his sutures only through the tendon and muscle. His tendon-tucker was an ingenious device, and I am of the opinion that he deserves more credit than he claims for having thus facilitated the performance of this operation.

In a paper published April, 1902, Colburn[10] describes an operation which he performed, and he states that it was first described by him in a discussion at the session of the American Medical Association in 1888: "The *suture* was *introduced, passing through the* tendon at its point of attachment, thence beneath the capsule along the upper margin of the tendon, and backward to the point of entrance. The single suture is then drawn and tied, the conjunctival flap returned to its place and held by a suture." Colburn also describes various other methods of tucking a tendon and shows a cut of a double hook he had used, shaped out of another instrument, and also a crude device made from a pair of ear forceps, to aid in taking the tuck. In addition to the above-described methods, there are others who have done work along similar lines.

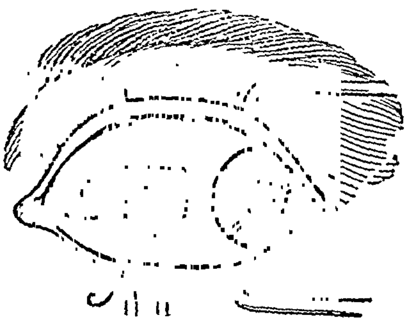

Fig. 2.—Tucker Introduced.

In February, 1902, my method[11] was described, but I have since improved it by the incorporation of certain details. This reason, and the additional fact that many ophthalmologists have written requesting a more detailed explanation, induces me to present this description.

DESCRIPTION OF AUTHOR'S METHOD OF PERFORMING THE TUCKING OPERATION.

To avoid confusion and to enable the reader to secure a more definite idea of the operation, the tucking of an internal rectus will be described. In many cases the external rectus is first tenotomized, then a flap of conjunctiva is dissected up and turned back toward the internal canthus, and Tenon's capsule is freely opened so as to clearly expose the tendon of the internal rectus from its insertion backward for a quarter of an inch. A strabismus hook is now placed under the tendon from above and made to emerge below; the tendon is lifted from the globe to facilitate the introduction of the tucker.[12] The prongs of the tendon-tucker being crossed, the one toward the internal canthus, being uppermost, is placed under the tendon (passing it in at the lower border of the tendon); the strabismus hook is now removed (Fig. 2), the screw head at the distal end of the instrument is turned to the right, causing the upper prong to pass toward the cornea as the lower prong passes toward the internal canthus; this produces the tuck in the tendon as the prongs are separating and causes the eye to turn inward. The tuck should be large enough to secure the desired effect.[13] Catgut sutures are now placed in the two layers of tendon midway between the prongs as follows: *Carry the needle of one suture under the upper border nearly to the middle of the tendon, bring it outward through the two layers and tie it; place another suture in the same manner, including nearly the lower half of the two layers of tendon (Fig. 3), and tie it.*[14] This leaves the nutrient artery undisturbed between these two ligatures. Now carry the needle of a doubly armed silk suture through the two layers of tendon just back of the *upper* catgut ligature from within outward, then up through the conjunctival flap from within outward; pass another similar doubly-armed silk suture just back of the *lower* catgut ligature from within outward and through the conjunctival flap; pass the needle at the other end of the *upper* silk suture underneath the conjunctiva into the episcleral tissues (above and internal to the cornea), bringing it out through the conjunctiva; now tie with only one knot (*so that it can be regulated later*) these two ends of this *upper* silk suture (Fig. 4). While an assistant holds the two ends of this suture, release the tucker (loosening it by turning the screw head) and remove it. Now insert the second needle of the *lower* silk ligature below the cornea into the episcleral tissues and tie in one knot the two ends of this *lower* suture in the same manner as the *upper* suture was tied. The pressure on the eyeball exerted by the tendon-tucker disturbs for the time being the exact position of the eyeball; *it now having been removed*, the two eyes may be compared and measured and the silk sutures tightened until the desired effect has been secured. These sutures will not slip as they pull against the catgut ligatures at one end, and are inserted into firm scleral tissue at the other. *After the desired effect is secured the second knots are tied* (Fig. 5).[15] *It will be observed that these regulating silk sutures also serve to stitch the conjunctival flap into place.*

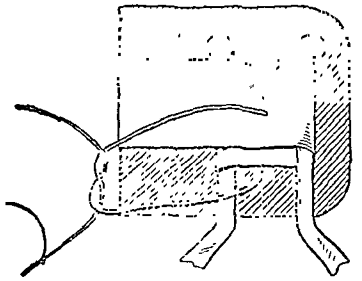

Fig. 3.—Placing of catgut ligatures after tuck has been made.

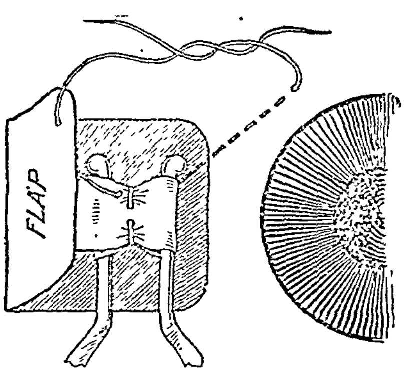

Fig. 4.—Showing placing of upper regulating (or retention) suture.

This operation is adapted to any case where an advancement operation is indicated and is found of especial service in those rather difficult cases where strabismus has resulted from an overcorrection of an opposite strabismus.

It is preferable to use cocain anesthesia for all muscle operations, as general anesthesia disturbs the physiologic balance; for instance, in a case of convergent strabismus, the eyes may diverge when the patient is asleep and the operator can not, therefore, determine the effect *of his operation until the patient is awake.* The surgeon can, however, perform this tucking operation, inserting the sutures and tying only one knot in the silk *regulating sutures, and when the patient is thoroughly awake, under cocain anesthesia, these regulating sutures may be adjusted so as to secure parallelism and the second knot may then be tied.*

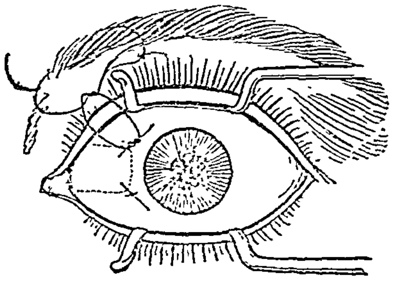

Fig. 5.—Tying of silk sutures.

The advantages of the tucking operation over any advancement operation when the muscle is severed, as given by Savage,[16] are: "First, it is easier of accomplishment; second, its plane of rotation is less likely to be changed when there is no indication for changing it;

---

[12] This instrument is universal, i. e., it can be used on any of the recti muscles. Many of the instruments have been imperfectly made, the *commonest fault* being a sharp point and inefficient hook at the ends of the prongs so that the instrument slips out during the operation. If correct, the instrument will cause no such annoyance.

[13] Chromicized catgut is best to use, as ordinary catgut sometimes absorbs too quickly.

[14] The needle is easily introduced through the two layers of tendon by tilting the tendon-tucker so as to lift the prong nearest the cornea.

[15] A bowknot may be tied and the ends brought out through the nearer canthus where they may be fastened to the cheek or nose with collodion, thus allowing for more regulation by tightening or loosening the next day or later.

[16] G. C. Savage: Ophthalmic Myology.

third, the stitch is not so likely to cut its way out, and, and if it does so, or if the knot should become untied, the case would be no worse than before operation; whereas, if either of these accidents should happen to an advancement, before adhesion has formed, the recession of the muscle might be farther back than its original attachment."

In addition to these advantages, I claim for my method:

1. Exactness. Perfect adjustment of the eye may be secured at the time of operation when tying the silk sutures after the tuck has been taken. (In nearly all advancement operations the operator is obliged to estimate the amount of the effect desired and does not know until his operation has been completed the exact amount of effect that has been produced.)

2. Security. When the operation is completed the stitches can not slip and the tendon will remain where it has been placed.

3. Ease. The operation is very easy of performance, made so by the use of the instrument.

4. Flexibility. The smallest or the greatest amount of deviation may be produced.

5. Strabismus of high degree. The greatest degree of effect can be produced when accompanied by a tenotomy of the opposing muscle, and thus a strabismus of the highest degree can be corrected by operation on one eye alone if desired.

DISCUSSION.

Dr. G. C. Savage, Nashville, Tenn.—My operation differs from Dr. Todd's in several respects, one being that there is less trauma in mine. Dr. Todd's operation is a combination of my tucking operation and the Laglieze lapping advancement operation. These three operations are the only ones that should be done for giving added power to a muscle. In neither of these operations is the tendon of the muscle severed. Again I wish to be recorded as saying that no rectus muscle should ever be cut entirely loose from the globe, either for setting back its attachment or as a preliminary for advancing it. It would frighten me if I were to cut a tendon entirely across. My muscle shortening operation can be done with the aid of the Todd tucker, or the Tenney or Valk folder, but I prefer to use two large strabismus hooks. The technic of my operation is simple and the traumatism is slight. I make a cut near to, and parallel with, a border (lower if the muscle is an externus or an internus) of the muscle, through the conjunctiva and capsule. Through this incision I pass one of the large hooks beneath the tendon, carrying it forward to the insertion. Lifting the tendon with this hook, I pass one of the two needles (the suture is armed with two needles) through the incision and make it penetrate the tendon near its upper border and at its insertion, and pass it on through capsule and conjunctiva. An assistant then inserts the second hook and carries it back beneath the belly of the muscle as far as possible and now slightly raises the muscle. Still holding the first hook, I now pass the second needle through the incision to a point of the muscle similarly related to the muscle plane with the point of puncture of first needle, and at such a distance behind the attachment as may be judged necessary; the needle is now pushed through muscle, capsule and conjunctiva and the part of the suture under the muscle is drawn into position parallel with it. The same needle is now passed through the conjunctiva, capsule and muscle near its lower border, immediately beneath the second puncture, and is brought out through the cut. The thread is now drawn on until the loop rests against the conjunctiva. The second hook is now removed and I now pass the same needle through the incision, beneath the tendon, and push it through the tendon near its lower border and at its insertion, and on through capsule and conjunctiva, being careful that the third and fourth punctures are in a plane parallel with the rotation plane of the muscle. I now pass the two needles through the two holes in the suture plate and complete the operation by tying a surgeon's knot on the silver plate; and in doing so I draw that part of the muscle beneath the loop into contact with the tendon at its insertion, thus shortening the muscle to that extent. It is a simple operation, easily done and efficient. The muscle capsule and conjunctiva are all included in the stitch. The knuckle of tissue thus formed needs no stitch to flatten it, for it soon disappears by absorption. This suture needs no anchoring sutures to strengthen it.

A mistake made in this operation and in other operations requiring a stitch is in allowing the suture to remain in too long. The stitch should be removed on the fifth day, even a day earlier if there is too much irritation excited by its presence. I always use silk. In the Laglieze operation the conjunctiva is incised over the tendon and turned back. A strabismus hook is passed beneath the tendon for the purpose of lifting it, when one needle of the double-armed suture is passed through the muscle after the manner of sewing on goods, thus placing a loop of thread beneath the belly of the muscle. Each of the two needles is now passed into the scleral tissue just as far in advance of the insertion of the tendon as the loop already taken is behind the insertion. The scleral punctures must be related, ordinarily, to the plane of rotation as are the puncture and counter-puncture in the muscle. In tying the surgeon's knot that part of the tendon and muscle between the insertion and the loop is drawn over the insertion to the scleral stitches, and is kept flat against the globe. This done, the conjunctival wound is closed by one or more sutures. The scleral stitch should be taken parallel with the canal of Schlemm, and behind it.

It is now clear that the operation shown on the manikin by Dr. Todd is a combination, with some modifications, of my muscle-shortening operation and the Laglieze lapping attachment operation. My objection to the tucker shown by Dr. Todd is that, if one wishes to change the plane of rotation of the muscle to cure a complicating cyclophoria it would be hard to accomplish, whereas it is easily done when the strabismus hooks are used. The Todd operation is a good one, the chief objection being the amount of trauma inflicted. More effect can be gotten from the Laglieze operation than from mine or Todd's.

Dr. Wendell Reber, Philadelphia—I am compelled to say that I do not think advancement is an easy operation. One must be doing a great many of them to make it at all easy. All the gentlemen with whom I have talked would rather do any other operation than an advancement. Tenotomy is easy; as to the result one gets, that is different. Whether a muscle is or is not to be cut away from its attachment depends on whether we aim at cosmetic effect or binocular vision; if for cosmetic effect it does not make any difference. It is generally done for that purpose and binocular vision is not a frequent result. That operation which enables us most clearly to see what we are doing seems to me the most commendable. The Worth operation is one to be carefully considered. I find it comparatively easy to do, and the effect secured at the operation is not lost. I confess that Dr. Todd's operation has one element to make it desirable and that is the ease with which the effect can be regulated after the anesthesia has worn off. When Dr. Todd brought out his first tucker I used it in three or four cases, and while we were not enthusiastic about it, we thought that perhaps we had not used it enough to become proficient; I felt that the tucker was in the way all the time and that the effect was likely to be a temporary one. All the sutures should be fast so that the operation may be made more definite. I think the Worth operation is to be preferred; the reaction is slight and the effect is permanent.

Dr. L. Webster Fox, Philadelphia—I had the pleasure of having Dr. Todd demonstrate his tucker operation in my clinic last Monday. I had attempted the operation several times, but the result was not satisfactory. Dr. Todd explained to me that the instrument I was using was not made correctly. I failed to bring about a good result by an improperly made instrument, so that it is not fair to condemn an operation until you have seen the surgeon who devised it, use the instrument himself. Dr. Todd performed the operation in my clinic very successfully, even with the very inferior instrument in my possession.

DR. OSCAR WILKINSON, Washington—I have been with Dr. Worth in a great many of his operations and have watched the results, and in my own practice no other advancement operation has given such good results. The operation depends largely, of course, on the object we wish to obtain and the amount of defect to be corrected. Where there is a large defect I should be skeptical as to the results of the tucking operation. It may be very valuable where the defect is slight, and it is certainly an ingenious idea.

DR. MARK D. STEVENSON, Akron, Ohio—I make a long, vertically curved incision through the conjunctiva, the center nearly touching the limbus, the ends curving away from the cornea. Tenon's capsule is next opened and the conjunctiva and capsule being pushed well back the muscle is seized by my advancement forceps and then cut free from the sclera. A sharp needle on a silk suture is next passed from without inward through the junction of the upper and middle third of the tendon and is then passed outward through the upper margin of tendon, and again passed through the tendon just behind the first point of entrance. It is then carried near the edge of the cornea and passed deep through episcleral tissue into the sclera. The needle on the other end of the suture is likewise used on the lower portion of the tendon and the two being first tied in a single knot, are tightened until effect required is secured, when a surgeon's knot may be made. All superfluous tissue should be removed. By this suture the upper and lower portions of the tendon are securely held, while the middle portion also affords support by the cross piece of the suture. The circulation in the middle portion is not interrupted, however, and only one knot is necessary.

DR. JOHN E. WEEKS, New York City—Any operation that necessitates doubling the tendon or muscle into a cord is certainly theoretically imperfect. The operation of Dr. Savage is such an operation. That difficulty has been avoided to some extent by the last speaker. The ideal operation is one that will maintain the normal width of the tendon, in addition to accomplishing the result desired. In order to maintain the width of the tendon, sutures must be entered at the upper and lower borders of the tendon. If only two sutures are used the middle portion can not be fastened as it should be, but with three sutures the width of the tendon can be controlled perfectly. My experience has led me to the conclusion that deviation of the muscle in any way imperils the result of the operation. For some years I used the advancement by tucking as devised by de Wecker, with very good results. One can not tell by half a millimeter the amount of the effect that will be produced by any operation. Another thing that is detrimental is the strangling of a portion of the tendon. That is done when the middle or the sides of the tendon are tied. It can be avoided by quilting the sutures. It is important to go well into the scleral tissue in passing the bulbar sutures. Another thing, do not delude yourselves in believing that a sufficient plastic process will be set up in four or five days to retain the advanced muscle. It ordinarily requires a longer time. Leave the sutures in from seven to ten days in order to be assured of the permanent retention of the tendon in the position in which it is placed at the time of operation.

DR. W. E. LAMBERT, New York City—I should like to substantiate what Dr. Weeks has just said. I am not an advocate of the tucking operation. I find advancements, or resections and tenotomies perfectly satisfactory.

DR. J. L. BORSCH, Philadelphia—Dr. Todd in his paper says that he can overcome a secondary strabismus by tucking the muscle that allowed the eye to deviate. The tendon, in a secondary strabismus, is so retracted that in most cases it can hardly be found; and what is advanced is the capsule, and the eye is thus straightened. It has been my privilege to assist de Wecker in many operations for capsular advancement, and have performed many myself, and fail to understand why an operation so simple and so effective should be modified. The manner of placing the sutures, it has been said, prevents their slipping; if the sutures are of the proper kind this will not occur. Dr. Todd assures, you can regulate the effect exactly with his method. This can also be done by grasping the capsule in the broad forceps, but in the majority of operations one must overcorrect a few degrees for a day or two. As for judging the amount of deviation corrected, I wish to say, that by using the de Wecker strabometer, which is extremely simple and portable, you can measure the exact deviation of the eyes and regulate the operation accordingly. I venture to say that the fraternity who do many operations will bear me out in the statement that we must simplify and not complicate operations in ocular surgery. For myself I am not ready to abandon the de Wecker operation.

DR. F. C. TODD—The great number of operations that have been described is evidence that we are not satisfied with what has been done so far in this work. As to Dr. Savage's criticism that torsion could not be effected by my operation, I would say that that is one of the advantages of the use of the instrument; the torsion can be easily regulated. In the second case I operated on I was obliged to produce torsion. By changing the axis of the instrument and inserting the scleral sutures above or below, as the case may be, the desired effect may be readily produced. Of course, the idea of the ligatures above and below is to prevent the cutting of the suture along the fibers of the tendon, which takes place in many of these operations and, as it seems to me, would take place in Dr. Savage's operation. I would remind Dr. Weeks that while he cuts off that portion of the tendon I ligate it, and I san not see that it makes any difference whether it is removed by atrophy or cutting; the results are the same; we do not care to preserve that portion of the tendon. Another advantage of this method is that the flap lies down and makes a smaller lump, which later disappears. In regard to the administration of chloroform, in these cases I rarely use chloroform; I prefer not to. As to the matter of pain, of course, many of these operations are somewhat painful, but that depends largely on the pulling of the muscle. With this instrument the pull is gradual and steady, while the pain is caused mostly by jerking the muscle. Now someone has spoken of doing a tenotomy. Each case must be treated on its merits. I would suggest that where one eye is involved it might be wise to do a tenotomy and an advancement, but where you have an alternating strabismus or where the movement of the two eyes is about equal we might desire to do two advancement operations.

THE PASSAGE OF DIFFERENT FOODSTUFFS FROM THE STOMACH.*

WALTER B. CANNON.
Assistant Professor of Physiology, Harvard Medical School.
BOSTON.

In the transfer of food from the stomach to the intestine two factors are concerned, the gastric waves of peristalsis and the pyloric sphincter. It is now known that under normal conditions the peristaltic waves course from the middle of the stomach to the pylorus without interruption during the whole of a digestive period. How the waves will affect the food is determined by the action of the pylorus. If the pylorus remains closed, the repeated waves over and over again churn the food with the gastric secretions; if the pylorus opens, these same waves act as the motive power to force the food onward.

The determinative function of the pylorus was recognized by the fathers of medicine, for they gave the ancient terms *pylorus* (keeper of the gate), *rector* and *janitor* to the sphincter, and assumed that it possessed a "will" which fixed the fate of ingested food. Van Helmont, in the days when the learned confused mysticism with science, presented his reasons for believing that the pylorus was the seat of the soul. It is certain that this wonderful sphincter holds the chances for good and evil in many of the most essential processes of digestion. The retention of food in the stomach to undergo gastric digestion, the gradual delivery of food from the gastric reservoir into the region of intestinal digestion, so gradual that the important digestive processes near the pancreas shall proceed regularly and without disturbance; the checking of irritants in their onward passage through the alimentary canal—all these functions are in the control of the pyloric sphincter.

---

*Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Pathology and Physiology.

Differing views of the way in which the pylorus opens and permits the food to pass have been set forth. Oppenheimer,[1] in 1889, and Rossbach,[2] in the next year, declared the food was all thoroughly mixed with the gastric juice, and that only four hours or more after eating did the sphincter relax and allow the stomach to empty. These observations, however, have not been substantiated; the errors in them probably were due to the nature of the method employed, for both clinical findings with the stomach tube, as Ewald and Boas[3] have demonstrated, and studies with the *x*-rays on the undisturbed subject,[4] prove that the stomach is not emptied all at once at the end of gastric digestion, but progressively during the period. In an investigation of the passage of food from the stomach we have, therefore, to consider agencies maintaining an intermittent closure of the pylorus, agencies which usually keep the channel closed, yet occasionally open it to permit portions of the digested food to advance.

Both mechanical and chemical agents have been supposed to determine the emptying of the stomach. Rossbach,[2] for example, thought that the stomach emptied only at the completion of gastric digestion, because the muscular contractions at that time were (under the conditions of his observations) more intense than before. enzoldt,[5] after an extensive study of the periods during iich various foods remain in the stomach, noted that ch foods as delayed the appearance of free hydrochloric acid remained longest in the stomach. Verhaegen,[6] on the other hand, declared that it mattered little in the passage through the pylorus whether the food was acid or neutral. In criticism of these statements, it may be said that Rossbach's observations were made on morphinized animals, with opened abdomen, conditions known to disturb the normal activities of the digestive tract; and in Penzoldt's[5] studies, although the amounts of food are stated, no attempt was made to have these amounts uniform, or to have the food of the same consistency. Furthermore, Penzoldt was dependent on securing remnants of the food by means of the stomach tube, a procedure which furnished no data concerning the rate at which the stomach was emptied, and was also objectionable in interfering with the digestive processes. This method, moreover, leaves the investigator in doubt as to which of the factors, the gastric peristalsis or the pylorus, caused the retardation of the food. Verhaegen's[6] conclusions are based on observations with the stomach tube on only four individuals, two of whom were admittedly pathologic. In the presence of strong evidence against his conclusions, the small number of cases observed by him must furnish him inadequate support.

Because of the differences of opinion which the above discussion has shown to exist, and because of the importance which the passage of food from the stomach bears both to physiology and to practical medicine, further investigation of the factors concerned in the process is desirable.

THE METHOD OF INVESTIGATION.

In studying the agencies controlling the pyloric passage, it is well, for the sake of simplicity of conditions, to employ foods predominantly proteid, fat or carbohydrate. Such foods were used in this investigation. Boiled beef, free from fat, boiled whitefish and the white meat of fowl are examples of proteids which were fed; beef suet, mutton and pork fat are representatives of the fats; starch paste, rice, and potatoes, of the carbohydrates. In all cases full-grown cats, deprived of food for the twenty-four or thirty hours previous to the experiment, served for the observations. The food was invariably given in uniform amount, 25 cubic centimeters, and with uniform consistency, the consistency of thick mush. Before the food was given to the animals it was mixed with 5 grams of subnitrate of bismuth. Comparison of subnitrate of bismuth with other insoluble heavy salts has shown that it has no peculiar effects on the movements of the alimentary canal; and clinical studies by Schüle[7] have proved that the addition of subnitrate of bismuth to food does not interfere with gastric motility. The animal thus fed with food mixed with bismuth subnitrate was exposed to the *x*-rays, and the movements of the food in the stomach and small intestine observed by means of the shadows cast on a fluorescent screen. The observations were recorded at regular intervals, one-half hour, one hour, and every hour thereafter for seven hours following the feeding. The records consisted of outlines of the shadows of the food, traced on transparent tissue paper laid over the fluorescent surface. Inasmuch as the diameter of the intestines varies only slightly, the area of cross-section of the contents may be disregarded, and the aggregate length of the shadows of the food in the small intestine may be taken to indicate the amount present. By comparing the aggregate lengths of the shadows cast by the intestinal contents it is possible to know the relative amounts of food in the intestine at different times as well as the relative amounts of different foods present in the intestines of different animals at the same time after eating.

It is obvious that the method has defects. For example, loops of intestine are not always parallel to the screen, and the loops not parallel may not always form the same angles with the screen, and they would, therefore, be variously foreshortened. It may be said in answer to this objection that the animals were stretched on their backs and the abdominal wall flattened both by the stretching and by the pressure of the fluorescent screen, so that the loops must lie nearly parallel to the screen, except, possibly, at short dorsoventral turns from one loop to another. That these turns were not a serious source of error was proved by massage of the abdomen, which rearranged the coils; tracings made before and after such treatment showed only slight variations in the aggregate length of the shadows. Another possible defect of the method arises from such overlapping of the loops that two loops, or parts of two loops, cast a single shadow. Care was always taken to obviate this error by separating by pressure with the finger loops lying close together. Still further faults of the method are found in the variations in the thickness of the food masses in the intestine, and the changes due to absorption, which proceeds at different rates with the different foods. But these defects must be regarded as slight, especially in the early stages of intestinal digestion, when compared with the great and characteristic differences in the amounts of food present in the intestine when carbohydrates, fats and proteids are separately fed.

What these differences in the treatment of the three kinds of foodstuffs by the stomach are, will now be stated. The results here set forth are based on between 600 and 700 observations on 80 to 90 cases.

RESULTS.

The characteristic differences in the aggregate length (in centimeters) of the intestinal content with the various foodstuffs at definite times after eating are illustrated by the following average figures:

Hours after feeding.	0-½	1	2	3	4	5	6	7
Fats (15 cases)	5	9	14	17	16	13	13	9
Proteids (10 cases)	1	5	18	21	23	19	17	14
Carbohydrates (14 cases)	8	30	39	33	25	19	14	6

Note that the carbohydrates and fats both begin leaving the stomach soon after they are ingested; but the carbohydrates leave rapidly, while the fats leave slowly. The curve representing the carbohydrate rapidity of passage would have a quick rise to a high maximum at the end of two hours, then a slow drop; the curve for fats would be a long, low curve, with no prominent maximum point. The figures for proteids are of especial interest, for they show that the proteids begin to pass out much later than either carbohydrates or fats (in many cases of proteid-feeding nothing left the stomach during the first half hour, and frequently nothing was out at the end of an hour, though peristaltic waves were running regularly from the beginning), and, moreover, after the proteids begin to leave the stomach, they leave slowly. The curve for proteids would show a slow rise to a maximum at the end of four hours, and then a gradual fall.

Many confirmations of these figures have been secured. For example, when proteids are fed first and carbohydrates later, the proteids are pressed more into the pyloric while the carbohydrates lie more in the cardiac end of the stomach. Under these circumstances, the presence of the proteids near the pylorus delays the discharge of the carbohydrates, as the following comparison of average figures in two such cases with the average proteid figures will clearly show:

Hours after feeding.	0-½	1	2	3	4	5	6	7
Proteids (10 cases)	1	5	18	21	23	19	17	14
Proteid first, carbohydrate second	2	6	15	21	29	34	28	22

On the other hand, when carbohydrates are fed first and proteids second, the presence of the proteids in the cardiac end of the stomach does not materially check the exit of the carbohydrates. A comparison of average figures in two such cases with the average carbohydrate figures will make this relation clear:

Hours after feeding.	0-½	1	2	3	4	5	6	7
Carbohydrates (14 cases)	8	30	39	33	25	19	14	6
Carbohydrates first, proteids second	4	23	35	28	25	18	14	7

The most significant feature of the above tables is undoubtedly the remarkable difference between the figures for carbohydrates and for proteids. Why are the carbohydrates, which are not digested by the gastric juices, permitted to go quickly onward into the intestines, where they are digested, while the proteids, digested in the stomach, are retained there to undergo digestion? What fine mechanism of the digestive economy could see to it that the gastric part performs its function well when food it acts on is present, and lets it waste but little time or energy with food it can not change? Such apparently purposive functioning recalls the ancient attribution of a "will" to the pylorus, supposed to control the movements of material through the channel with deference to the body's welfare. Is there, however, a more simple and direct explanation of these activities?

If the presence of free acid in the stomach and near the pylorus is a stimulus to the relaxation of the pyloric sphincter, the interesting mechanism is largely explained. Both carbohydrate food and proteid stimulate the gastric secretion in abundance, as researches on dogs by Pawlow and his pupils,[8] and as clinical studies on man, have shown.

Now, inasmuch as carbohydrates provoke an acid secretion and do not unite chemically with it, free acid is at once present in the stomach; whereas with proteids, since they join with the acid secretion to form acid proteids, free acid does not make its appearance for some time. Thus the carbohydrates would begin almost immediately to pass through the pylorus. Thus proteids would be delayed.

The hypothesis that the presence of free acid in the stomach opens the pylorus can be tested. Feeding a carbohydrate mixed with an alkaline fluid would delay the appearance of free acid in the stomach, and, according to hypothesis, should also delay the passage of the food. The similarity between the average figures from two cases fed on crackers moistened with 1 per cent. sodium bicarbonate, and the average figures for proteid, shows how closely the addition of the alkaline fluid makes the figures approximate.

Hours after feeding.	0-½	1	2	3	4	5	6	7
Proteids (10 cases)	1	5	18	21	23	19	17	14
Alkaline carbohydrate	0	4.5	19	28	31	29	25	21

The converse of this process also was tried. Proteids changed to acid proteids, and freed from all excess of acid were fed and the rate of discharge recorded. The following average figures of three cases of acid proteid (lean beef acid with hydrochloric acid), compared with the average figures for carbohydrates, show a remarkably close relation throughout:

Hours after feeding.	0-½	1	2	3	4	5	6	7
Carbohydrates (14 cases)	8	30	39	33	25	19	14	6
Acid proteid	6	30	43	39	28	21	14	10

These two tables show that alkaline carbohydrate, like ordinary proteid, leaves the stomach slowly, while acid proteid leaves the stomach quite as rapidly as carbohydrate food. All cases which have been tested harmonize with the idea that conditions delaying the appearance of free acid in the stomach delay the discharge of the food, and conditions favoring its appearance hasten the discharge.

At first thought it might seem that acid added to carbohydrate food would still further increase the rapidity of the discharge. Such, however, is not the fact. When 0.4 per cent. hydrochloric acid is added to crackers in sufficient quantity to make a thick mush, the figures secured do not vary much from those secured when crackers and water are fed:

Hours after feeding.	0-½	1	2	3	4	5	6	7
Crackers and water	10	23	43	46	43	30	19	5
Crackers and 0.4 per cent. HCl	8	18	41	51	45	25	21	17

But if free acid is the stimulus to the opening of the pylorus, why does not the addition of free acid to the food open the pylorus and hasten the emptying of the stomach? How is the paradox to be explained? It is here that the reflexes from the duodenum must be considered.

In 1893 Hirsch[9] observed that the introduction of acid into the duodenum through a duodenal fistula inhibited for a time the passage of food by the opening. Serdjukow,[10] one of Pawlow's students, confirmed the work of Hirsch. It was impossible to tell by the methods these investigators employed whether the acid in the duodenum checked the gastric peristalsis, or compelled a prolonged contraction of the pyloric sphincter. Observations with the *x*-rays show that, although there is no cessation of gastric peristalsis after the advance of acid food into the duodenum, the pylorus does not for some moments relax. The duodenal reflex of Hirsch and Serdjukow must, therefore, affect the pyloric sphincter.

---

[8] Pawlow: The Work of the Digestive Glands. English translation, London, 1902, p. 35.

[9] Hirsch: Centralblatt für klin. Medicin. 1893, xiv, p. 73.

It is now possible to explain the slow passage of fats from the stomach. Fats are unlike either proteids or carbohydrates in that they are seldom eaten as a pure, or even predominant, foodstuff. When fats in almost pure form are fed to animals the gastric peristalsis is often observed to be slight, and, according to Pawlow, the flow of gastric juice is not stimulated. When fats enter the duodenum, however, they cause the same reflex that acid causes.[11] Thus, by a diminution of the influence opening the pylorus, and by a continuance of the influence closing it, the fats are long retained in the stomach, and only slowly passed along.

THEORY OF THE ACTION OF THE PYLORUS.

Evidence has been presented in the foregoing paragraphs which would explain the remarkable activities of the pylorus in the presence of food as largely due to chemical stimulation. The degree of contraction of the pyloric sphincter when at rest varies,[12] but the effect of particles of food in keeping the sphincter contracted[4] indicates that the mere mechanical presence of food in the stomach will produce a closure of the pylorus. After food has reached the stomach all evidence points to the probability that the signal for a movement onward into the intestine is the appearance of free acid. Free acid on the stomach side of the pylorus would thus be the stimulus to open the pylorus and initiate the chemical control of the sphincter. The opening of the pylorus permits the exit of a portion of the acid chyme. There is proof that acid in the duodenum closes the pylorus and keeps it closed. Thus the acid chyme would go forth from the stomach, and, with its acid, close the gate behind it. But acid in the duodenum is known to be the stimulus for the flow of the alkaline secretions of the pancreas.[13] No inorganic acid is normally present beyond the first few inches of the small intestine.[14] The acid, therefore, is here neutralized. As the neutralizing of the acid proceeds the stimulus to the closure of the pylorus is weakened, until the acid in the stomach can again open the pylorus. Again the food would pass out and the gate close till the duodenal changes finish their slower course.

Thus, automatically, carbohydrates, on which the stomach works no change, would go early and quickly into the intestine, where they meet their proper ferment; thus, automatically, proteids would be retained in the stomach to suffer alteration by the gastric juice, and only after such alteration be permitted to go on; thus, automatically, the intestine would be saved from oppression by overwhelming discharges from the gastric reservoir; and, by this same automatic mechanism, the gastric secretion, harmful to the action of the intestinal ferments, is rendered innocuous because of its admission, little by little, into the duodenum.

DISCUSSION.

Dr. Winfield S. Hall, Chicago—I will note in a few words the relation between Dr. Cannon's findings and something that I have discovered in my experiments in dietetics in my department, namely: Patients with acute gastritis can take with comfort egg lemonade earlier than they can take any other form of food, and it is our custom to give that at the beginning of feeding after they have had the period of rest that Nature is calling for in an acute case of gastritis. The earliest food that we can give is very small doses of egg lemonade every two hours. Dr. Cannon's discoveries regarding the influence of acid make it evident that this egg lemonade, being in the condition of acid albumin and already half digested, passes readily right on through the stomach, without exciting or irritating it, and down into the duodenum, where its digestion is completed.

Dr. Charles Harrington, Boston—Did the gluten curve take that form on account of the presence of carbohydrates, which are commonly found in large amounts in commercial glutens?

Dr. D. H. Bergey, Philadelphia—How does Dr. Cannon account for the prolonged time of absorption from the stomach? Our usual idea has been, I think, that food passes from the stomach in a much shorter time than his curves indicate. Does he believe that the food really remains in the stomach for that length of time, or is it due to the shadows cast by the subnitrate of bismuth remaining on the mucous membrane?

Dr. Fenton B. Turck, Chicago—One interesting point that Dr. Cannon has brought out here is that the presence of acid or alkali does not materially influence the peristaltic motion and that the chemical composition of the food does not influence the motions of the stomach. The peristaltic waves he found extending over to the pylorus were independent of the character of the stomach contents. In this difference between starch and proteid, the more rapid passage of the starch was not due to increased peristaltic waves caused by carbohydrates, nor to lessened peristaltic waves influenced by diminished stimulatory action of the proteid on the muscle fibers of the gastric wall, but to difference in the opening or closure of the pylorus. This somewhat corresponds with my own observations, published last year, on the influence of various chemical bodies on the gastric mucosa. To the entire mucosa were applied various chemical bodies—acids, alkalies, varieties of food, such as bouillon, peptones, starch—and they did not seem to influence the peristaltic motions a particle; but as soon as tension was brought to bear on the muscle wall of the stomach by distending the stomach with air or water, introduced directly, or indirectly in a rubber bag inserted in the stomach, it promptly caused rhythmical contractions—peristaltic waves. The degree of tension or intermittent tension, within limits, increased these peristaltic waves proportionally. By prolonged and excessive tension, lasting several hours, the gastric muscle of the dog became fatigued and resulted in dilatation of the stomach. I also observed, as Dr. Cannon has done, the influence of acid on the mucosa of the stomach and duodenum, causing the opening and closing of the pyloric door; and this work that Dr. Cannon has brought out in another direction not only confirms my observation of the negative effect of chemical stimulation or excitation of stomach movements, but goes further and gives an explanation of the manner in which the pyloric door is opened. Does this, then, conflict with the popular theoretical idea that excessive acid in the stomach causes spasm and a closure of the pylorus, as is held by clinicians? I am impressed more with the physical and mechanical effect of the stomach contents in causing rhythmical contractions, which necessarily includes relaxation as well as contraction. The acidity may be an incident indirectly influencing the passage of food through the pylorus.

Dr. Claude A. Smith, Atlanta, Ga.—Has Dr. Cannon made any observations on the effect of exercise on the passage of these different foods from the stomach?

Dr. W. B. Cannon—In order to find the reason for gluten leaving the stomach early and in large amounts, just as carbohydrates do, I took equal amounts of gluten paste and of the proteid (meat proteid) which I had been using, and put into each the same amount of 0.4 per cent. hydrochloric acid. In about thirty minutes the free hydrochloric acid had entirely disappeared from the meat, but the free hydrochloric acid was still present in the gluten paste twenty hours after being introduced. Evidently this gluten does not readily unite with the acid; so that, if acid is poured out on the gluten in the stomach, free acid must be present immediately, just as it is in the case of carbohydrates. I used Dr. Johnson's gluten, and I understand that a large amount of starch is present in it. The figures I have presented do not show the amount of food in the stomach. The figures show the amount of food in the small intestine. The stomach may be empty while food is still present in the small intestine. It is true, as Dr. Turck has suggested, that I have seen no considerable variation in the peristalsis. Gastric peristalsis runs regularly from the beginning to the end of digestion unless stopped by emotional disturbances. I have not examined the effect of exercise, but one of my students is at the present time at work on the effect of exercise and other factors.

THE DIAGNOSIS OF ENLARGED BRONCHIAL LYMPH NODES.*

ALFRED FRIEDLANDER, M.D.,
CINCINNATI.

Among the phenomena of the developmental period of childhood, there is none more striking perhaps, than the activity for the lymphatic system. The lymph glands constitute an apparatus for filtration. Given the factors of rapid growth, on the one hand, and of poorly developed powers of resistance, on the other, and it can readily be seen that the period of childhood must necessarily be accompanied by marked reactive irritation and inflammation of the entire glandular system. During this period the mucous membranes are prone to irritation, with resulting inflammation. Added to this, there is the disposition, often hereditary, not infrequently aggravated by faulty conditions of development and hygiene, to chronic inflammation of mucous membrane, skin and bone. Under such conditions it is not surprising that the filter system should be taxed to its utmost capacity—hardly less astonishing that we should find very often, in the inability of this system to hold the various poisons localized—an avenue for general systemic infection.

From the nature of things we should expect to find inflammation of the tracheobronchial glands to be enormously common. The three groups of these glands—the tracheal, the tracheobronchial and the peribronchial intercommunicate freely. They receive the lymphatics of the trachea, the bronchi and the lungs and the pleuræ. But, more than this, through the deep lymphatics of the neck, lying both in front of and behind the carotid sheath, they are in direct communication with the cervical glands. Again, these glands are directly connected with the mesenteric lymph nodes.

It will thus be apparent that very many different factors and very diverse conditions may induce inflammation of these glands. Of these factors there are many that are particularly frequent in childhood. Diseases of the nasopharynx and irritation of the bronchial mucosa are excessively common. Indeed, if we consider the morbidity of but two diseases, which invariably cause a good deal of irritation of the bronchial mucosa and thus of the bronchial glands, namely, measles and pertussis, the frequency of the condition can not be doubted.

SIMPLE ADENITIS.

Simple adenitis of these glands is very frequently only the precursor of the far more serious tubercular involvement. There is no need to quote many figures as to the frequency of such tubercular infection. As long ago as 1865 Steiner and Neuritter showed that in 302 autopsies in tuberculous children, the bronchial lymph nodes were affected 275 times (91 per cent.). And the oft-quoted figures of Northrup, who found the nodes tubercular in every case, in a series of 125 autopsies, irrespective of the cause of death, hardly need comment. It is not only true that tubercular bronchial adenitis is present in at least four-fifths of all cases of tuberculosis in children, but—and this is the more important—it is certain that in the majority of these cases, it is the primary lesion.

There can be no doubt that many cases of enlarged bronchial glands tend to recovery, without subsequent tubercular infection. The danger of such infection, however, is always present, and it is, after all, this factor which adds so greatly to the gravity of the condition.

If we consider that the morbidity of measles is probably greater than that of any other infectious disease; if we add to this the enormous frequency of pertussis, influenza and of such forms of irritation as adenoid vegetations, the statement that almost every child, at some time or other, exhibits a bronchial adenitis, does not seem exaggerated. Of course, in many cases, such a simple adenitis recedes with the disappearance of its cause. With the subsidence of the special infection, the strong and otherwise healthy child recovers, and is to all intents perfectly well again. Yet every adenitis of this sort is but a preparation of the soil whereon, under proper condition of diminished vitality and lowered bodily resistance, the ubiquitous tubercle bacillus may grow and flourish. And other things being equal, the longer such adenitis persists, the greater the danger of tubercular infiltration.

TUBERCULAR ADENITIS.

Yet, even though it be admitted that tubercular disease of these glands is enormously common, it is not to be forgotten that this form of tuberculosis—so long as it remains localized—is still decidedly amenable to treatment. Indeed, tuberculosis, in infancy and childhood, is essentially a disease of lymphatic structures. It may remain so localized for months and years, gradually progressing to other and more incurable forms. There is, it is true, the ever-present danger of general infection; and owing to the anatomic peculiarities, to the peculiarly intimate relation of these glands to other lymphatic systems, such infection is particularly apt to occur in the form under consideration, namely, enlargement of the bronchial glands. A recent writer insists on "the predominating influence of the tracheobronchial glands, as compared with any other lymph glands, in the origination of tubercular processes elsewhere in the body."

DIAGNOSIS OF ENLARGED BRONCHIAL GLANDS.

From the viewpoint of prophylaxis, as well as of direct therapy, it is thus very desirable that we should be able to make a definite diagnosis of enlargement

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

The percentage of lymphocytes is here practically normal, although the eosinophile count is very high—without new demonstrable cause for the eosinophilia. Indeed a subsequent count showed normal proportions of eosinophiles. Without exception, in all of the cases studied, there has been the distinct picture of lymphocytosis—usually very well marked—when the clinical condition allowed a diagnosis of enlarged bronchial glands to be made.

In this connection it may be permissible to refer to the figures of a count, previously reported, of a case of so-called pertussoid, following influenza, in an infant of 8 months. In this case the percentage of lymphocytes was 69.6 per cent. the polymorphonuclears numbering only 30 per cent of the whites. A certain degree of lymphocytosis is, of course, to be expected in infancy, but figures reported in this case are certainly suggestive.

The number of cases studied (10) is not large enough to warrant the drawing of any absolute conclusions. Nevertheless, the fact that each of these cases showed a lymphocytosis, stands out prominently. And its significance is enhanced by the fact that in the cases which could be followed up, the lymphocytosis disappeared, to a degree, with the subsidence of the symptoms.

It is indeed not unreasonable to expect that, where there is marked irritation or inflammation of the lymph glands—we should see a reactive lymphocytosis. The best illustration of this we see in lymphatic leukemia. But this is not an isolated example. Thus in typhoid there is relative lymphocytosis, and as we know, marked inflammation of the mesenteric lymph glands. Again, in the early stages of syphilis, with acute adenitis, lymphocytosis is the rule. On the other hand, we know that all forms of adenitis are not accompanied by lymphocytosis. In Hodgkin's disease, for instance, lymphocytosis is only occasionally found. So, too, in the adenitis accompanying malignant disease there is ordinarily no lymphocytosis.

With reference to the blood find in general tuberculosis it may be said that, except for a reduction in hemoglobin, there are no important blood changes—unless there be secondary infection. As Cabot says, "whether or not tuberculosis of the abdominal or other internal lymph glands affects the blood, I am unable to say."

CONCLUSIONS.

In the absence of more extended series of observations than the present one, too much theorizing is certainly out of place. Yet it seems fair to emphasize the fact that in two diseases where we know clinically that a tracheobronchial adenitis exists, namely, pertussis and measles, there is a constant lymphocytosis. And in the 10 cases of enlarged bronchial glands studied, lymphocytosis was found in every case. In the light of these cases it seems fair to assume that the lymphocytosis of pertussis and measles is to be explained by the irritation of the tracheobronchial gland.

If after further investigation and after study of a much larger series of cases, the observation of constant lymphocytosis be confirmed, we shall have an additional sign—and I believe a valuable one—looking to the more definite diagnosis, and, therefore, to the more successful treatment of the condition of enlarged bronchial glands.

22 West Seventh Street.

DISCUSSION.

Dr. R. B. Gilbert, Louisville, considers that the situation of these bronchial glands at the bifurcation, and against the posterior wall of the trachea, renders them, when they are enlarged, a potent source of irritation. They are enlarged more or less in every case of bronchopneumonia, and especially in measles. The method followed by Dr. Gilbert in cases of persistent cough following measles, and which ordinary cough remedies fail to relieve, is to give full doses of potassium iodid, and if the cough is due to the irritation caused by enlarged bronchial lymph nodes, it will frequently be rapidly relieved by the administration of this remedy. These conditions are most likely to be met in persons with a syphilitic or scrofulo-tubercular diathesis.

Dr. George N. Jack, Depew, N. Y., said that it seems strange to him that such an ancient disease as asthma, as well as other common respiratory conditions, should be attributed to a spasmodic contraction of the air tubes, as the anatomist has clearly demonstrated that it is absolutely impossible for one of these tubes to contract. Therefore, the condition must be due to direct obstruction. The bronchial lymphatic glands are the dumping grounds of the blood. The blood passes through them and rids itself of its impurities. If, then, the blood is loaded with waste and useless material while in the lungs for oxygenation and purification, it will naturally deposit as much as possible of this useless substance in the bronchial lymphatic glands. The blood, stool, urine and clinical history of the patient must be our chief guides in diagnosis.

Dr. Theron W. Kilmer, New York City, is of the opinion that the bridge of tissue sometimes formed after the removal of adenoids as the result of adhesions, and which gives the same symptoms as the adenoids themselves, should be broken down with the finger, a month after the adenectomy. He has never observed pseudo-pertussis or pertussoid forms of cough and is inclined to look on them as myths. He has never found bronchial lymph nodes during life. Even if the diagnosis is made, he knows of no efficacious treatment to promote their reduction.

Dr. Louis J. Lautenbach, Philadelphia, emphasized the fact that peculiar malformations of the bony structure of the palate are often associated with these obstructions in the posterior nares. This peculiar condition of the bony structure may escape attention unless it is looked for. He also referred to the frequent occurrence of deafness resulting from nasal disease, catarrhal deafness being practically always so caused. In cases where adenoids are said to recur after removal it is often not a true recurrence, but a new growth brought about by the same underlying conditions which produced the first enlargement.

Dr. Alfred Friedlander said that it is perhaps going a little too far to assert that the coughs Dr. Gilbert referred to are always due to adenoids. He has seen many improve without removal of the adenoids, and thinks that when there is tracheobronchial adenitis a primary localized tuberculosis is present and it is surprising that more of these cases do not develop a generalized tuberculosis. He considered it our duty to treat these cases precisely as we would treat a localized tuberculosis elsewhere. Even when there is only a suspicion of such a condition, the patient should be given the benefit of the doubt and treated accordingly. The importance of removing adenoids in children is appreciated, but too much stress should not be laid on this one factor alone. It has become the rule to ascribe all the ills of children to adenoids, but it is a fair assumption that sometimes the illnesses are not due to this condition.

Domestic Opium.—In his annual report Secretary Wilson of the Department of Agriculture states that opium poppies have been grown successfully in Vermont, both the white-seeded and the blue-seeded varieties yielding good crops. Experiments are now being carried on to ascertain the possibility of obtaining morphin directly from the plant. If the experiments prove successful, the American product may replace the oriental opium as a source of morphin.

THE IMPORTANCE OF AN EARLY AURAL EXAMINATION IN ACUTE DISEASES OF CHILDREN.*

JAMES F. McKERNON, M.D.
NEW YORK CITY.

The prominence of aural disease has been brought very frequently before the profession for the past decade; but I know of nothing in aural disease of children of greater importance than an early recognition and treatment of some of the conditions I shall enumerate.

It is more particularly to call your attention to certain forms of aural disease, especially in children, not easily recognized by the pediatrist or general practitioner, and therefore all the more important, or if recognized, usually too late to be of value from a prophylactic standpoint, that this paper is written.

You are all familiar with the complications frequently accompanying the acute exanthemata, but usually your first intimation of an aural condition is to have the little patient complain of earache, or if it be a young infant, you expect him to pull or tug at the affected ear, and cry out with pain, thus drawing your attention to the local condition. That such manifestations do take place in a certain number of cases, there can be no gainsaying; but this number is small in comparison with the number of cases that never complain, nor give the slightest evidence of any ear trouble being present until a discharge is noticed coming from the external auditory canal.

It is of these cases that I wish to speak more in detail, and of how important it is that frequent otoscopic examinations be made that we may early recognize and treat any pathologic conditions found, and thus prevent the patient from undergoing a long and dangerous sickness that might be caused directly or indirectly by such an aural condition.

TECHNIC OF EXAMINATION.

Otoscopic examination in very young children is by no means an easy matter to those not constantly practicing it; in the first place, the specula used are too large; secondly, the auricle is drawn upward, backward and outward, and in this way the major portion of the lumen of the canal is shut off from our view—whereas if we draw the auricle gently downward and backward, we open the canal and expose to view the deeper structures.

Then, too, we will oftentimes find the circumference of the meatus lined with cerumen, and if we attempt to force the speculum beyond this, we not only hurt the patient, but our view is obstructed by a speculum, the distal end of which is filled with wax. In these cases it is always well to syringe the canal with warm, sterile water, and remove the obstructing cerumen before we attempt a further examination.

CONDITIONS OF TYMPANIC MEMBRANE.

In many cases, on inspecting the drum membrane, when middle ear disease is suspected, we see a white, rather prominent looking drum, showing not the slightest vestige of congestion, but if we here bring to our aid a cotton tipped probe, and gently brush the surface of the drum membrane with it, the white looking drum will be replaced by a bulging, reddened and angry looking surface, which shows the true condition of the middle ear. The pressure behind the drum having been so great as to cause a rapid exfoliation of the external epithelial layer; and this on inspection can easily be mistaken for a drum membrane free from involvement.

Such an error is made again and again, and then when pus suddenly appears in the canal a few hours after the examination, the observer is surprised at such a rapid infection, and wonders how so large an accumulation of fluid or pus can form in such a short time, when in reality it was present all the time.

Another picture, the otoscope examination reveals in cases complicating the exanthemata, is that of the upper half of the drum membrane looking normal save for a slight tinge of congestion along the superior border of Shrapnell's membrane, while the lower half, and particularly that portion of the drum corresponding to the tubal opening in the middle ear looks lustreless; and has a grayish, mottled appearance. This shows that already the mucous membrane of the tube and that portion around the tubal entrance is swollen and pouring forth a serous exudate which demands an immediate evacuation through an opening in the drum if we wish to cut short the process, and prevent the disease from attacking structures higher up.

Another picture frequently seen, and when present usually accompanied by severe earache, is that of a drum membrane showing decided congestion of the whole upper third; the lower two-thirds retaining its lustre; neither bulging nor fullness is present, but the superior and posterior portion of the membranous canal is intensely reddened; the excessive pain being no doubt due to the involvement of this connective tissue fold in the membranous canal.

Here early incision is advisable, even before bulging takes place in order that we may prevent extensive attic involvement.

AURAL COMPLICATIONS OF THE EXANTHEMATA.

In young children suffering from the acute exanthemata, it is, I believe, just as important that their ears should be examined each day, as it is that they should be seen for their general condition, for, after all, the mortality is quite as large in these diseases from the aural complications as from any other; and many of the cases of deaf mutes, as well as the legion of chronic purulent ears with their sequelæ might be avoided if in the future this precaution were taken. The usual time for an aural condition to develop, complicating these acute diseases, is any time after the third day, and it is all the more important that these aural examinations be made frequently, for in a large number of the cases, there is no symptom pointing to an aural condition until after the damage has occurred, namely, a spontaneous rupture with destruction of a portion of the drum membrane, which might easily have been avoided, had otoscopy been practiced frequently.

When the general practitioner or pediatrist is treating any of the acute inflammatory diseases, and the disease is subsiding, and the existing temperature is high and out of all proportion to that stage of the disease, it is wise to perform otoscopy, as in many of these cases here will be found the cause of the temperature, and a speedy relief from anxiety will follow as the fever drops when the ear is appropriately treated.

AURAL COMPLICATIONS IN OTHER DISEASES.

Gastrointestinal Diseases.—This condition occurs frequently in diseases other than the exanthemata; as for example, complicating an acute gastrointestinal condition, where the local symptoms are fast disappearing and yet the child is fretful, uneasy, and the temperature remains high. All other conditions excluded, if the are examined quite frequently, the cause for the child's latent symptoms is found here. Again, take a patient convalescing from pneumonia or the "grippe," when the temperature varies and remains high, and the physician for several days can not locate the cause of the existing fever, but thinks it is a latent "grippe" or an incomplete or delayed resolution, or that that much maligned disease, malaria, is at work on the patient's system again—if when such conditions present themselves, the ears be examined carefully many times, here will be found the cause of the disturbance, when, before examination, it was not even suspected.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

Follicular Tonsillitis.—It is also advisable that frequent examinations of the ear be practiced during an attack of acute follicular tonsillitis, though here pain is usually a prominent symptom in children owing to the fact that there is usually lymphoid hypertrophy present in the naso-pharynx, and the swelling existing here causes pressure on the eustachian tubes, and the pain is at once referred to the ear.

A prophylactic measure of the greatest importance in young children, is to see that all adenoid tissue be removed before the winter months, as the presence of this tissue is very often the exciting cause of an acute middle ear suppuration, and very frequently such a suppuration will not cease until the exciting cause, namely, the adenoids, has been removed. It is then often astonishing to see how rapidly resolution will take place without any local treatment whatever directed to the , after this source of irritation has been removed; or if it does not clear up quickly the treatment necessary to bring about a favorable result will occupy a much shorter period of time.

Hypertrophied Tonsils.—Hypertrophied tonsils should also be sacrificed when there is a history of frequent attacks of ear trouble in children, as enlargement in this region causes engorgement around the orifice of the eustachian tubes, and this is an exciting factor, even though somewhat remote from the seat of the disease.

Coryza.—Another condition in children requiring toscopic examination is when an acute coryza is pres , for here, with the frequent and forcible blowing of the nose, bacteria-laden mucus is often forced into the opening of the tube, with the result that an acute condition of the middle ear is speedily established, and frequent examinations reveal to us the disease in its very earliest stages, thus enabling us to check the process without impairment of audition or any of the unpleasant sequelæ coincident with middle ear suppuration.

Nasopharyngeal Catarrh.—In many cases of mild sopharyngeal catarrh, where all the symptoms are ractically absent, save temperature, if the ear be examined here will be found the cause of this temperature, for toscopy will show us acute middle ear changes taking place and this condition is not infrequently found where no adjacent local manifestations are present, not even a imple cold.

Typhoid.—Another disease, and one often overlooked, where otoscopic examinations are necessary, is typhoid fever; for here the aural complications when they do exist, if overlooked, leave the audition permanently impaired. There is rarely a symptom present in this disease to call one's attention to the ear, and many a case of labyrinthine disease owes its origin to an attack of typhoid fever.

Mastoiditis.—One of the complications of acute middle ear suppuration in young children, mastoiditis, may, think, be appropriately mentioned here, as in the minds of many practitioners, such a complication does not exist unless the ear is found to be displaced forward, and a swelling of more or less magnitude, with edema, is found over the mastoid.

Given a case of acute middle ear suppuration following any one of the many diseases which it may complicate, and this disease having subsided, we have a running ear to treat, with one other symptom present, namely, temperature. This temperature is usually not high, but varies from 99 to 100.5, continuing for several days with morning remissions and evening exacerbations, without any apparent change in the character of the secretion coming from the ear, except a slight diminution in quantity. We find also on cleansing the external auditory canal, and wiping away the secretion from the point of perforation in the drum membrane that pus oozes through this opening drop by drop as we wipe it away. In such a condition as this, delay is extremely dangerous, for there is already an infiltration of pus throughout the mastoid structure and an operation for mastoiditis here is imperative, for if allowed to progress, in a few days the case will present the gross physical signs described above.

It is very difficult, and frequently impossible, to elicit the slightest evidence of pain in young children when we press on the mastoid process, even though the mastoid be filled with pus, for these little patients will scream quite as much when the normal side is being examined, as they do when the diseased side is gone over; and if one waits for the appearance of edema over the mastoid, as an indication for operation in these young children, he is increasing the danger tenfold by inviting one or more of the complications to take place.

Another fallacy in connection with this phase of aural complications, is, that when a swelling takes place behind the ear in young children, and there is a subperiosteal accumulation of pus present, that it is quite sufficient to make an incision, the so-called Wilde's, in the soft parts over the swelling, evacuate the pus, pack it, and believe nature will do the rest. A condition like this treated in such a way almost invariably leads the patient into danger from the complications arising thereafter, to say nothing of the permanent impairment of the hearing, for a chronic aural discharge will be the result of such treatment.

Abundant clinical evidence has been brought to bear on this point, from all modern otologists, and the importance of opening the mastoid, and draining the middle ear in these cases has, in my experience, been amply demonstrated during the past two years. In a large hospital service, 57 cases of subperiosteal abscess were present in young children ranging from 5 weeks to 6½ years of age; in all of these the mastoid was opened and the middle ear drained posteriorly, and 56 of the mastoids contained pus. In the one in which pus was not present, granulation tissue was found throughout, and the structure was just on the point of breaking down.

In these cases do not be content with a simple incision and evacuation, for if this only be done a dangerous legacy is left these little patients, and one to which unfortunately, all too many succumb. Even though in many cases the external evidences have disappeared, the ear still continues to discharge, because it has not been properly drained, and this discharge is the result of the mastoid necrosis, which is still progressing, and sooner or later he who is treating such a case is brought to face a still more serious condition, namely, that of one or more of the frequent intracranial complications of otitic origin.

Another serious complication of acute aural suppuration which is by no means infrequent in young children, is that of a primary involvement of the jugular bulb, without disease of any of the mastoid structure. Here the principal symptom is mainly one of temperature, which ranges all the way from normal to 107 F. The rises are rapid and the remissions to normal or near it, quite as abrupt. In adults, we usually associate such a condition with more or less well defined symptoms, the principal one, aside from the temperature, being the presence of a chill or chilly sensation. In young children, we hardly ever observe this symptom, but in the place of it the little patients have cold hands and feet preceding the rise in temperature. These with a discharging ear may be the only symptoms present for several days, until the child gradually becomes septic. When the observer suddenly awakens to this fact, it is usually too late to save the life of his patient.

The question may be asked, "How can a primary involvment of the jugular bulb take place, without first involving the mastoid structure?"

It can take place very easily under the following conditions:

With an active, virulent infection of the middle ear cavity, and the presence of a large irregularly shaped bulb encroaching on it, and these two spaces separated by only a thin, parchment-like wall of bone, it becomes a very easy matter for the infection to pass through this thin plate of bone, and poison the blood current, before such infection would have time to travel its usual pathway, namely: Through the mastoid structure. That such a complication is not infrequent, can be readily comprehended, when in my experience alone, five such cases have been encountered during the past six months. The successful treatment of this condition is an early operative procedure.

Eczema of the External Auditory Canal.—Another condition where an otoscopic examination is indicated is where we find an eczema present of the external auditory canal and meatus, and sometimes extending over nearly the whole auricle, and down the side of the face. This condition is caused in nearly all the cases by a scanty serous discharge coming from the middle ear, and this moisture lies in the canal until an exfoliation of the superficial epithelial layer takes place, and the little patient's first symptom is an intense itching at the meatus, accompanied by a very natural desire to scratch, which is indulged in with the result that in a very short space of time, a well-developed eczematous area is present. Even though this complication be treated faithfully and conscientiously, it will recur from time to time, because the etiologic factor in its production has not been discovered, namely, the scanty acrid discharge from the middle ear. Had an examination of the ear been made on the appearance of the eczema, these little sufferers might have been spared weeks of pain and annoyance, instead of enduring the torture they are allowed to undergo.

A rather infrequent complication of this eczematous state in young children is the appearance of a diffuse circumscribed external otitis or furuncle, caused by scratching the meatus. When this condition is present and well developed, it many times is mistaken for mastoiditis, owing to the large amount of swelling which is present over and around the mastoid process. An aural examination will always clear this up and the true cause be discovered in the external auditory canal and meatus.

CONCLUSION.

I would in no sense be understood as always advocating the calling in of an aurist for the making of these frequent examinations, but in each case, when the general practitioner or specialist in children's diseases is first called to examine the case, the physical examination is an incomplete one unless the ears are included. It is a simple matter for those not accustomed to perform otoscopy, by a little practice, to be able to do it well enough for all practical purposes.

To the general practitioner of the future will belong the credit of a decrease in the number of cases of chronic purulent ear disease with their sequelæ, for if recognized and treated early, an acute condition need never reach the chronic stage. If, however, a chronic ear disease be encountered, no time should be lost in an attempt to rectify the pathologic condition, so that the patient may retain his audition; and also to prevent the possibility of an intracranial condition occurring later.

62 West Fifty-second Street.

DISCUSSION.

DR. HERMAN JARECKY, New York City, stated that the routine examination of every child suffering from an acute condition should always include a careful inspection of the ear. Recently Dr. Kerley was called to see a child that was being treated for empyema. On examination, Dr. Kerley found that the case was one of acute middle ear disease. Dr. Jarecky saw the patient on the following day and did a paracentesis: the temperature dropped to normal and all the symptoms of the supposed empyema disappeared. Dr. Jarecky said that, in the adult, a view of the drum membrane is obtained by pulling the auricle upward and backward, in infants it must be drawn downward and backward, and in older children simply backward.

Acute middle ear disease during the acute exanthemata is particularly liable to affect children who are suffering from adenoids, because the drainage is imperfect. In typhoid fever the ear complication is probably frequently overlooked on account of the general apathetic condition. In every case in which the ears are involved with bulging of the drum membrane, paracentesis should be done without delay. The simple operation can be done by the general practitioner as well as by the specialist. The ear should be properly irrigated with bichlorid solution or peroxid, and the drum membrane incised. In cases in which the posterior part of the wall is involved, we should not wait for bulging before incising the drum membrane.

DR. SAMUEL J. WALKER, Chicago, emphasized the necessity for examination of the ear in acute infectious diseases in children, and that middle ear disease may simulate almost any disease of childhood, such as meningitis, typhoid fever or pneumonia. He was called recently to see a child three years of age that was seemingly very ill. The child's father was a physician and had made a diagnosis of probable pneumonia. The patient was carefully examined, but Dr. Walker was unable to find any objective sign of pneumonia. On the following day the child's father was inclined to believe that the case was one of typhoid fever, but this diagnosis was practically excluded by the result of a blood count, which showed a leucocytosis of 28,000. On this second day the chest finding was still negative, so that pneumonia could probably be excluded. An ear specialist was called in, examined both ears, and pronounced them practically normal. The child, however, continued to show severe symptoms of acute infection. On the third day the ear man again saw the patient. At this time he found some redness and bulging of the membrane in both ears. Paracentesis was performed and there was a free discharge of pus followed by a rapid subsidence of all symptoms.

DR. SAMUEL MCC. HAMILL, Philadelphia, said that in his wards at the hospital, three out of seven cases of typhoid fever developed a complicating otitis media. In the majority of instances of this kind that he has seen the diagnosis was not made until the drum membrane had ruptured spontaneously. Most of these cases were in children, and in the majority of instances with which he has come in contact the complication has occurred almost at the point of defervescence in the course of the typhoid fever.

Dr. Theron W. Kilmer, New York City, asked Dr. McKernon if he advocates paracentesis in every case of bulging of the drum. Dr. Kilmer has seen the inflammation disappear in these cases under the use of douches of hot boracic acid solution, and without incision.

Dr. Louis Fischer, New York City, has found the temperature in suppurative conditions of the middle ear a rather uncertain guide. A child with scarlet fever, while progressing satisfactorily, is suddenly "restless during the night:" the temperature is 99; pulse, 120. The next day there is a discharge from the ear. Excluding the restlessness there is sometimes no indication of a suppurative process going on. He has come to look on the temperature as a not very positive symptom in acute suppurative otitis, especially during the infectious diseases. Many cases of suppuration of the middle ear are the result of mechanical infection through the nose and eustachian tubes by irrigation, etc. He believes that if we leave the nose alone, and do not irrigate, as is so frequently done in the acute infectious diseases, there will be fewer cases of acute otitis media.

Dr. S. W. S. Toms, Nyack, N. Y., emphasized the possibility of nasal cleansing setting up middle ear disease. About two years ago he saw a child with a purulent rhinitis, and made an effort to cleanse the nose by irrigations. The following morning the child developed a temperature of 104, and he found the left ear drum bulging. The temperature rose to 107 within three hours, and the child was in a desperate condition, the pulse being 186 and the respirations 84. An aural specialist was called in, who incised the left ear drum, evacuating no pus, but some bloody serum. The drum of the opposite ear was apparently perfectly normal. The child's general condition decidedly improved after the paracentesis, but the temperature did not drop more than one degree. The respirations and pulse also remained high. Dr. Toms frequently examined the right ear drum during the night, and the next morning found that it distinctly bulged. The otologist was again sent for and incised the membrane, evacuating a little bloody serum. Within three hours after this second paracentesis the temperature dropped to 100, and the child's further recovery was uneventful. Since this case, Dr. Toms has carried a head-mirror and speculum with him, and to examine the ears as a routine measure in case of acute disease in a child.

Dr. Thomas S. Southworth, New York City, said that in the acute infectious diseases, a number of patients will develop middle ear trouble, whether the nose is irrigated or not. He thinks that if the irrigation is done carefully and as much as possible of the septic material in the naso-pharynx is removed, the number of cases of complicating ear disease ill be decreased rather than increased. The aurist sees only the irrigated cases which develop otitis, but he does not see the larger number saved from otitis by irrigation. Of course, the irrigations should be made very gently, preferably by fluid poured into the nose from a spoon.

Dr. F. L. Smith, Bridgeport, Conn., said that it has often been very difficult for him to decide just what to do and when to operate. Not long ago he saw a patient who complained of an earache. He examined the drum membrane, and from its appearance did not suspect any serious middle ear trouble. During the night the drum ruptured spontaneously, and there was a purulent discharge from the ear.

Dr. Charles G. Kerley, New York City, said that he gave his experience with 51 cases in a paper at the recent meeting of the American Pediatric Society in Detroit. In 34 there was no pain nor other local manifestation of ear involvement. The only symptom indicating the middle ear as the seat of the trouble was the elevation of temperature. In the treatment of children it is just as important to make a careful examination of the ear as of the heart or lungs.

Dr. J. F. McKernon agreed with Dr. Walker that middle ear disease may simulate almost any disease in the category. In typhoid fever the ear symptoms are most commonly observed during the stage of defervescence. If typhoid patients could have the ears examined systematically after the first week, Dr. McKernon believes that we could often prevent serious middle ear trouble, with resulting labyrinthine disease, and the dry catarrhal form, in which the prognosis is so absolutely bad as a sequela of typhoid fever.

Dr. McKernon said that he would incise the drum membrane in every case if it were bulging, and in a certain number of cases he would even make the incision when the bulging was absent, depending on the physical signs and symptoms presenting. He disagreed with Dr. Fischer in regard to the temperature in middle ear disease. There are a certain number of cases where there is no temperature at the time we see the patients; these patients may have had a temperature before we saw them, or may be patients who are more or less resistant to temperature changes, but in the vast majority of cases the temperature is one of the predominating features throughout. In streptococcus infection the temperature is usually high and continuous until the pus is evacuated, whereas in the mixed infection with the pneumococcus the temperature is not so high. In staphylococcus infection the temperature is not very high. In adults the temperature is not so predominating a factor as in children. He has not used a douche in the nose nor nasopharynx for ten years. If the child is old enough, he holds its head sideways, and allows the fluid to run through gently. If there is much secretion in the nose it can be wiped out with a cotton-tipped probe. He never uses the douche nor spray, and disapproves of their use in diphtheria or scarlet fever. In the acute middle ear diseases in children, the presence of pus is not always necessary. There may be infected serum just as well as pus, and the former calls for evacuation quite as much as the latter. It is well known that many of these cases apparently recover without surgical interference, but a large proportion will show evidences of pronounced impairment of hearing in future years.

SOME PHYSICAL SIGNS IN INFANTS AND CHILDREN NOT SUFFICIENTLY EMPHASIZED.*

SAMUEL McC. HAMILL, M.D.
AND
THEODORE LE BOUTILLIER, M.D.
PHILADELPHIA.

Several years ago we began a systematic examination of the heart and lungs of infants and children in our out-patient services in the Howard and Polyclinic Hospitals, with a view to confirming certain observations which we had made, some of which had not been sufficiently emphasized in the literature, and others of which were at variance with the results reported.

CONDITIONS IN THE LUNGS.

Our observations relate exclusively to normal or functional conditions. In relation to the lungs, they are three in number: First, an area of impaired resonance under the left clavicle. Second, the area of transmission of the bronchial type of breathing as heard over the root of the lung. Third, the influence of position on the percussion note in infants.

An Area of Impaired Resonance Under the Left Clavicle.—This sign was first noted accidentally by one of us in a child convalescent from bronchopneumonia. In this instance, owing to the absence of all other signs of pulmonary consolidation it was interpreted as probably indicating enlargement of some of the lymphatic glands. In the study of subsequent cases of bronchopneumonia, this same area of impaired resonance was observed and found to persist until the patients passed from under observation. The constancy of its presence led us to search for it in the chests of infants and children free from pulmonary diseases. These studies, which have extended over a period of two years, have convinced us that this is a normal manifestation, constantly present up to the age of nine or ten years, and not infrequently as late as the thirteenth year. The degree of impairment varies in different individuals. It is difficult to elicit in early infancy. It is always present under the inner third of the clavicle. It occasionally extends outward to the midclavicular line, gradually fading as this point is approached; it extends in a downward direction to the first interspace and not infrequently blends into the cardiac dullness.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

Unfortunately, we are not able to give an entirely satisfactory explanation for its presence. In a few postmortem studies, which we have made with the idea of elucidating this point, the only feature noted, which may have some bearing on its production, was the exposed condition of the great vessels. The left lung in early life lies more posteriorly than in the adult. The anterior border, in not extending so far forward, leaves the great vessels, as it does the heart, in more intimate contact with the chest wall, which naturally results in producing a higher pitched note over the portion of the chest immediately overlying. This probably does not account for the instances in which the impairment extends as far to the left as the midclavicular line, unless it be that the relatively extensive area of contact with the solid organs—the great vessels and heart—reduces the elasticity of the chest wall sufficiently to partially deaden the pulmonic resonance for a limited distance beyond the point of contact with these solid organs.

The importance of this observation is manifest. We have been taught, heretofore, that if there is any difference in percussion resonance over the apices, it is somewhat higher over the right. On the basis of this teaching, one would naturally look on an area of impaired resonance under the left clavicle as indicating some abnormality of the lungs, great vessels or lymphatic glands. It also has an important bearing on the determination of the upper area of cardiac dullness. In many instances, as stated, it blends into it, and in these, renders impossible its definite delimitation.

The Area of Transmission of the Bronchial Type of Breathing.—This is ordinarily heard over the root of the lungs, and varies greatly in different children. Posteriorly, it is usually limited to the interscapular space and supraspinous fossæ. It is often conveyed to the entire scapular area and it can sometimes be heard just above and in front of the angle of the scapula, about in the posterior axillary line—as a high-pitched, distant, bronchial murmur, which is sometimes so misleading that we have seen it mistaken for the bronchial breathing of consolidation. When heard here, it is usually bilateral, assuming that the child is examined in a position which renders breathing equal on the two sides. It is much more common in children under six years of age, although we have noted it after this period. Dr. D. L. Edsall tells us that he has sometimes noted the same thing in the examination of the adult chest, as well as in that of the child.

The Influence of Position on the Percussion Note in Infants.—It has been indefinitely stated in text-books, that placing a child on pillows or even in contact with the ordinary mattress, will, to some extent, deaden the sound produced by percussion of the chest. We have not, however, seen emphasized in the literature the striking differences on the two sides of the infant's chest, when it is examined lying on its side with the dependent lateral surface of the chest wall in intimate contact with the bedding—an incorrrect position which is commonly employed in the examination of the chest. Under these circumstances, the elasticity of the chest wall is destroyed, the lung is compressed, air enters it inadequately and, in consequence, there results a striking increase in the height of the pitch of the percussion note, which, when compared with the note on the opposite side, proves very misleading, unless one determines its origin by examining the infant with both sides of the chest free and symmetrical.

THE HEART.

In the study of the heart, we have considered: First, the position of the apex beat. Second, the outlines of the heart. Third, the venous hum. Fourth, the functional murmur. These subjects have been much under discussion and the opinions regarding them are much at variance.

The Apex Beat.—In studying the position of the apex beat, we have examined the children in the upright position, recording as the apex the point farthest to the left and lowest down, at which it was impossible for us to obtain any cardiac impulse. We found that the area formerly described as representing the apex beat, namely, the point of maximum intensity of the impulse, was so variable in its position and frequently so far removed from the left border of cardiac dullness, as to give a very definite idea of the position of the point of the heart. There is considerable variation in the position of the apex, as we have determined it, but it is much less than the variation of the point of maximum impulse.

We have always believed that the point of the heart remains in the fourth space and near to the midclavicular line for a longer period than is ordinarily supposed, and that after descending from the fourth to the fifth space, it almost constantly finds itself in the midclavicular line and occasionally outside of it; the approach to the normal position of the adult being made on a horizontal plane from this point. The results of our work have confirmed these views.

In a series of seventy-one infants under three years of age, examined in our dispensary services, we found the apex beat in the fourth space fifty-seven times. In seventeen of these it was just without the midclavicular line; in three, one-half inch without; in twenty-five, in the midclavicular line, and in twelve just within the midclavicular line. In fourteen cases, it was in the fifth space, just within the midclavicular line four times; one-half inch without the midclavicular line three times; just without once, and in the midclavicular line six times.

In a series of thirty-six cases, studied during the fourth and fifth years, the apex was in the fourth space twenty times; just without twice; in the midclavicular line seven times; and just within the midclavicular line eleven times. It was found in the fifth space thirteen times—once without the midclavicular line; eight times in the midclavicular line; three times just within, and once one-half inch within the midclavicular line. Three times it was apparently behind the fifth rib in the midclavicular line. Up to the end of the fifth year, therefore, the apex is found much more frequently in the fourth space than in the fifth space. During the following year, however, there comes a very abrupt change.

Thus, in thirty cases, it was found in the fourth space but eight times—once one-half inch outside the midclavicular line; twice in the midclavicular line; four times just within the midclavicular line, and once one-half inch within. It was noted twenty-two times in the fifth space—appearing twice one-half inch without the midclavicular line, eight times in the midclavicular line. six times just within the midclavicular line, and six times one-half inch within the midclavicular line.

In one hundred and thirty-eight cases, studied from the sixth to the twelfth year, it was noted but thirty-three times in the fourth space—most frequently in the midclavicular line, (eighteen times in the midclavicular line, seven times just within the midclavicular line, eight times one-half inch within the midclavicular line). In the remaining one hundred and five cases it was found in the fifth space—and again most frequently in the midclavicular line, namely, thirty-six times; twenty-eight times it was just within the midclavicular line, twenty-two times one-half inch within and nine times (during the eleventh and twelfth years) one inch within the midclavicular line.

It is worthy of note that, in none of the eleven cases observed in the twelfth year, was the apex beat found in the fourth space.

As the result of the examination of these two hundred and seventy-five cases, therefore. it may be concluded that, up to the sixth year, the apex beat is ound much more commonly in the fourth intercostal ace and in the midclavicular line and that, after this eriod, it is usually in the fifth space, in or just within e midclavicular line. Occasionally, however, it conues to beat in the fourth space even up to the elfth year.

Area of Cardiac Dullness.—With reference to deterning the outline of the normal heart, we have examd a series of one hundred and ninety-one cases. The ients have been examined almost entirely in the ight position. In infants under one year of age, the imbent posture was maintained because we found the results of outlining the heart with them in upright position was extremely unsatisfactory. Inr as we were able to compare the results in the positions, at this period of life, they were not very rent. The hands were used for both plexor and meter and the percussion stroke was made exely light—an absolute necessity in the outlining ese hearts, if one desires to obtain accurate re-

Probably the term accurate is not appropriately ed to the outlining of the heart of infants and ren. We do not agree with those who believe it is easier to outline the heart in children than ults. In the first place, the heart lies freer in est in early than in adult life, and consequently, re readily displaced. Aside from this, infants hildren are much more liable to extreme distenf the abdomen, which, in pushing up the agm, tends to push the heart upward and to the nd, what is probably still more important, the ely greater size of the liver and its frequent enents. give rise to an area of impaired resonance right of the sternum, which it is often impossible rentiate from the right border of cardiac dullness. We have endeavored, insofar as possible, to eliminate cases in which these conditions might have interfered with our results, but, notwithstanding these precautions, we submit our conclusions with a certain amount of trepidation. We are quite willing to adopt the words of Clifford Allbutt, in relation to this subject, which are as follows: "The facility with which modern physicians delineate and record the varying dimensions of the heart excites my admiration—a skill I can not hope to attain; the conditions of physical diagnosis seem to me indeed to be too inconstant for such appraisements."

In fifty-one cases, examined during the first three years of life, the upper border corresponded to the second rib thirty-four times, to the second space ten times, and to the upper edge of the third rib seven times. The right border was at the midsternum twenty-nine times, at its right edge fourteen times, and at its left edge eight times. The left border was in the midclavicular line sixteen times, just without twenty-one times, and one-half inch without fourteen times.

During the fourth, fifth and sixth years, in forty-one cases, the upper border corresponded to the second rib ten times, to the second space eleven times, and to the upper border of the third rib twenty times.

The right border extended to the left edge of the sternum once, to the mid sternum twenty-four times, to the right edge of the sternum fourteen times, and one-half inch beyond its right edge twice.

The left border extended one-half inch without the midclavicular line three times, just without sixteen times, and was in the midclavicular line twenty-two times.

During the seventh, eighth and ninth years, in fifty-five cases observed, the upper border was over the second rib eight times, the second space thirteen times, and the upper border of the third rib thirty-four times.

The right border corresponded to the left edge of the sternum five times, to the mid sternum twenty-two times, to its right edge twenty-three times, and was one-half inch beyond its right edge five times.

The left border was found one-half inch outside the midclavicular line fifteen times, in the midclavicular line thirty-six times and just within four times.

During the tenth, eleventh and twelfth years, in forty-three cases studied, the upper border corresponded to the second rib five times, to the second space eleven times, to the third rib twenty-seven times.

The right border was over the left edge of the sternum twice, over the mid sternum twenty-seven times, the right edge eleven times, just beyond the right edge once, and in two instances one-half inch beyond.

The left border was seven times one-half inch outside the midclavicular line, seven times just without the midclavicular line, twenty-nine times in the midclavicular line.

In the light of the above figures we conclude that the average outline of the heart for children under three years of age is as follows: Upper border, second rib; right border, mid sternum; left border, just without the midclavicular line.

From the third to the sixth year: Upper border, the upper border of the third rib: right border. mid sternum; left border, in or just without the midclavicular line.

From the sixth to the twelfth year: Upper border, third rib; right border, from the mid sternum to the right edge of the sternum; left border, most commonly in the midclavicular line.

The two remaining points to be considered, the venous hum and functional murmur, are of much more importance than the determination of the cardiac outline.

The communications in the text-books on these subjects are very scant. A considerable number have been contributed to the literature in the form of theses and essays, and in these one finds a very remarkable and inexplicable diversity of opinion as to the frequency, etiology, nature, time, distribution, and significance of these murmurs. Only a few observers admit that they are present, except with the greatest rarity, during the first four years of life; for instance, such a careful observer as Hochsinger[1] makes the statement that "during the first three years, systolic murmurs heard over the precordia are certainly of organic origin."

It is for the purpose of refuting statements such as these and with a view to elucidating some of the points above referred to, that we have made a careful, systematic study of a large number of children. We have examined children of all ages up to the twelfth year. We have accepted the general run of dispensary cases, excluding all febrile cases, those having deformities of the chest and those in whom the heart's action was abnormally rapid. We have not, in these cases, made systematic examinations of the blood. Where anemia was manifest on observation, it was recorded in our notes. The majority of our patients were asthenic children, with a degree of anemia, not manifest in the appearance. We recognize the unreliability of this method of excluding anemia, and it is very probable, that in many, and perhaps the majority of our cases, there may have been a slight degree present. But we do not believe that the anemia was the main factor in the production of the murmurs. We have noted marked anemias without murmurs and found them present in patients with a normal hemoglobin percentage. We are much more inclined to believe that these murmurs bear a closer relationship to the general nervous tone of the individual, which extends itself to the nervous mechanism controlling the condition of tone of the heart and vessels—conditions which may be secondary to any of the infectious or nutritional disturbances. What the possibilities of a diminution in the bulk of blood in children of this type are, we do not attempt to determine. If the defective conditions of hygiene under which they exist can yield such a result, it is possible that this may have some etiologic significance.

The Venous Hum.—In the study of the venous hum, we have made it essential that the hum should be present when the patient was examined with the head fixed in the median line. Turning the head away from the side under examination will always augment the murmurs and sometimes produce them where they had not previously existed. We have used a double stethoscope, with a chest piece three-quarters of an inch in diameter, and in its application used only sufficient pressure to bring its circumference in complete contact with the underlying surface. We have examined all of our patients in both the upright and recumbent postures.

In the two hundred and twenty-six cases in which we studied the venous hum, twenty-four occurred during the first three years of life, four of these being in the first twelve months. Following this, the number of cases was about the same in each year. In all but thirty-six, the hum was best heard over the right jugular vein. In the thirty-six in which this was not so it was best heard over the left. It was heard alone on the right side sixty-four times and alone on the left twelve times. In eighty-nine cases it was heard over both the right and left, being best heard in the right side seventy-seven times and in the left twelve. In thirty-eight instances the distribution was more extensive, the following being the most common: Over the right jugular, the intensity being greatest at this point, under the right clavicle, in the suprasternal notch, over the manubrium sterni and over the left jugular. Occasionally it was heard only over the right jugular and under the right clavicle. In several instances, the murmur was distinctly audible along the right edge of the sternum as low as the second costal cartilage, and in two instances, we heard it over the second left costal cartilage.

The murmur, as heard over the right jugular, was continuous in the vast majority of cases, having its *maximum intensity during the systolic period.* There was usually some reduction in the loudness of the sound during the end of systole with some augmentation in volume during diastole. In but six of these two hundred and twenty-six cases was the hum audible in systole alone, and in no instance did we hear it alone in diastole.

The influence of posture on the sound was striking. In only ten instances was the murmur audible when the patient was recumbent and in all of these it was much louder when the upright position was assumed.

The presence of this murmur over the manubrium sterni has interested us, in its relation to Eustace Smith's sign of enlargement of the bronchial glands. While the murmur disappeared in these cases when the patient was recumbent, it was again produced if the head was extended and sometimes when there was no hum present over the manubrium sterni in the upright position, it could be induced by having the head fully extended when the child was recumbent. The frequency of this phenomenon in cases in which there was an entire absence of other signs of enlargement of the glands, has led us to place very little reliance on this sign.

The extensive area of distribution of the venous hum may result in its being mistaken for murmurs at the base of the heart, or possibly for murmurs produced by lesions of the vessels. As has been noted in several instances, the murmur was audible as low as the aortic area and in two instances we have observed it in the pulmonary area. It is quite true that in all of these, if the patient was examined in the upright position, the murmur had the peculiar, humming, continuous sound which is characteristic of the venous hum, but in several instances, when the patient was placed in the recumbent posture, there persisted during systole a faint systolic whiff, which might readily have been mistaken for a murmur produced by lesions of the aortic or pulmonary orifice, or more probably, for a functional cardiac murmur. In the sub-joined study of inorganic heart murmurs we have noted a murmur, systolic in time, in the aortic area, which we believe to have been produced in this manner.

Functional Heart Murmurs.—We have studied these murmurs in two hundred and sixty-seven cases. Of this number, twenty-three occurred during the first three years of life (of these twenty-three, four having been noted during the first year, nine during the second and the remainder during the third). The figures during the remaining years are as follows:

---

[1] Allgemein. Wein. Med. Zeit., 1888.

4th year	20	9th year	27
5th year	19	10th year	32
6th year	36	11th year	23
7th year	35	12th year	13
8th year	39		

These figures probably do not indicate the relative frequency of these murmurs at the various ages indicated, for the reason that, in our dispensary service, the number of children treated between the ages of three and ten years is relatively greater than the number treated during the first two or the eleventh and twelfth year. Aside from this, the difficulties attendant on the satisfactory examination of infants in a large dispensary service are too great to make the recognition of faint murmurs possible.

The murmur was best heard, in the majority of instances, in the pulmonary area—in one hundred and eighty of our cases. The next point of maximum intensity was over the body of the heart, in the space between the third rib, the left edge of the sternum and a point within and above the apex beat. This applied to forty-five cases. In twenty-six, the murmur was best heard at a point slightly above and just within the apex. It was sometimes transmitted slightly beyond the apex beat and infrequently as far posterior as the mid-axillary line. In sixty-one of our cases, it was audible only in the pulmonary area; on the other hand, the area of distribution, in some instances, was very extensive. It was not an uncommon experience to find the murmur audible in the pulmonary area, over the body of the heart, at and beyond the mitral area, and, in twelve instances, in the aortic area.

In the vast majority of cases, the murmur was inaudible in the upright position and, in only four, was it heard in the upright position and not in the recumbent. In two hundred and ten cases, it was audible in the recumbent posture only, while in fifty-one, it was audible in both the recumbent and upright.

To determine how definitely the foregoing studies illustrated the frequency of these murmurs in children under three years of age, through the courtesy of Dr. J. R. Bryan, we were enabled to examine a series of cases in St. Vincent's Home. The result of this work is so interesting that, in order to emphasize it, we tabulate it and give it separate consideration.

It includes a series of thirty-four cases—nineteen of them being one year old or under, seven of them between one and two years and the remaining eight between two and three years. The hemoglobin was estimated in all of these children. We did not make a complete blood examination, believing that the percentage of hemoglobin would prove a sufficiently satisfactory indicator of the degree of anemia. Of the nineteen under one year of age, twelve were foundlings and seven were breast fed children. These two groups are contrasted because they illustrate so well the effects of the natural and artificial modes of nourishment.

Among the twelve foundlings we found a venous hum present four times (in each instance it was heard only during systole), and functional murmurs seven times. The character and distribution of these murmurs was much the same as in the cases previously referred to and therefore need not be described in detail. In one instance, the venous hum was present without functional murmurs, and in four instances the functional murmur existed without the venous hum. The percentages of hemoglobin, in the cases indicated, were as follows: 50, 60, 70 twice, 74, 76, 77 and 90. In the instance in which the hemoglobin was 90 per cent., both the hum and the murmur were present. One case

EXPLANATION OF ABBREVIATIONS.

In relation to posture "R" means recumbent and "U" upright. The upper letter in the column indicates the point of maximum intensity of the sound.
Distribution of Venous Hum: R.—Right side. L.—Left side. R. Cl. and L. Cl.—Under right and left clavicles. S. N.—Supersternal notch. M.—Manubrium.
Distribution of Functional Murmur: P.—Pulmonary Area, left interspace close to the sternum. M.—Mitral area. A.—Aortic area. B. H.—Body of heart (the portions of the heart not described under valve areas). 3 Sp.—Third left interspace within the parasternal line.
The time of the murmur is indicated by the abbreviations: S.—Systolic. D.—Diastolic. L. S.—Late systolic.

showed a hemoglobin percentage of 65 per cent. without either hum or murmur. The youngest child included in this series was two weeks of age, and in this case, both the hum and the murmur were noted. Four of the others were under six months of age. In the seven breast fed children there were no venous hums present. One child, who had recently passed through a severe attack of measles, had a functional murmur. This child had a hemoglobin percentage of 61. The hemoglobin estimates in the remaining cases were 70, 71, 80 twice and 83 twice.

The point which we desire specially to emphasize in this comparison, is the fact that, in the breast fed children, although in two instances the hemoglobin percentage was as low as in the children showing murmurs in the other set, there were no murmurs present. On casual observation, the condition of nutrition of some of the foundlings seemed quite as good as that of some of the breast fed children. On closer inspection, however, the former were seen to be more apathetic, their muscles more flabby and their general tone much lower. These differences in the condition of tone were striking. The mild anemias were about the same in the two sets; therefore, we are inclined to believe that the murmurs recognized were not dependent on the associated anemia, but rather on the differences in nutrition.

In the fifteen children over one year of age, the venous hum was found eleven times and the functional murmur thirteen times, and in two instances, the murmur was present without the hum. The venous hum, in these cases, with one exception, was continuous and in this one instance it was heard only during systole.

The hemoglobin percentage varied from 55 to 100 and, in the instance in which it was 100, both the venous hum and functional murmur were heard.

These observations are not in accord with the investigations which have been made. As intimated in the beginning of our paper, functional murmurs are almost universally stated to be absent under three years of age. One exception to this statement appears in a communication by Rheiner.[2] He says that he believes that functional murmurs, though unusual, do exist before the second half of the fourth year and that he has heard soft, inconstant murmurs in the pulmonic and mitral areas in apparently healthy infants in the first year of life, for which he has found no satisfactory explanation.

In reference to this subject, Holt[3] makes the statement that "accidental murmurs may be due to anemia and other blood conditions and, although not so common as in older patients, they are by no means rare even in infants."

W. L. Johnson[4] makes the statement that he has "seen two cases of febrile murmurs in young infants."

With these exceptions, we have found no reference to their existence except as very unusual manifestations prior to the third year.

DISCUSSION.

Dr. John Lovett Morse, Boston, has tried to obtain information regarding the size of the heart in children, and has not been able to find anything satisfactory. According to his experience, the right border of the heart in infants up to two years of age is from one to two centimeters to the right of the right border of the sternum. Functional murmurs are very common in infants, and he believes that in many cases a murmur can be heard at the upper part of the sternum if the head is held backward.

Dr. Louis C. Ager, Brooklyn, N. Y., asked whether the heart of the young infant is usually displaced much to the left in intestinal dilatation. His experience has been that it is crowded directly upward, but not much to the left.

Dr. R. B. Gilbert, Louisville, said that there ought to be a book on anatomy giving the structures of the various organs in young children. The various text-books on this subject are wholly misleading, and on that account he believes that we have all experienced difficulty in mapping out the heart in cases of suspected cardiac affections in infants. The same is true in regard to the caliber of the bronchial tubes, and there are a number of anatomic points bearing on diagnosis which show distinct variations in the child as compared with those in the adult.

CONGENITAL DISLOCATION OF THE HIP.

AN ARGUMENT CONCERNING THE METHOD OF ITS TREATMENT.*

HARRY M. SHERMAN, A.M., M.D.
Professor of Surgery in the University of California; Surgeon to St. Luke's Hospital, and Orthopedic Surgeon to the Children's Hospital.
SAN FRANCISCO.

There is a line of argument concerning the method of treatment of congenital dislocation of the hip, which is to-day being forgotten. I desire to review it because it opposes the reduction of the dislocation by any kind of forcible manipulation, and perhaps will tell against manipulation where but moderate force is used.

In 1899 I reported, at the New York meeting of the American Orthopedic Association, thirteen manipulative reductions; of these one is an anatomic and functional success, one is probably an anterior subluxation because of interposed capsule between the head and acetabulum, one was an anatomic success, but became ankylosed after an exploratory incision and consequent infection. Two of these have been verified by very recent, or comparatively recent, examination. The ankylosed one has passed from observation. There is nothing to add to the statement then made of the failures to maintain reduction in the other cases.

The previous year, 1898, at the Denver session of the American Medical Association, I reported, as part of a general report on the work I had been able to do, the case of a girl, 6 years old, with both hips out, on whom the manipulation plan apparently succeeded, but really failed. A second attempt again apparently succeeded on one hip and again really failed, and on the other hip the failure was a frank one. In this case I finally did arthrotomy and found that, in the joint in which the second attempt had apparently succeeded but had really failed, the interposed capsule, and the impossibility of putting the head through the narrow part in the capsule, was the cause of the failure; in the other joint the same obstacle existed and the capsule was full of bloody synovia, showing that the manipulations had been forcible and fairly well directed. Both hips were reduced by arthrotomy and the child left the hospital with each *in situ*, but her condition and whereabouts are not now known.

Since this operation, which was done in 1898, I have made no attempts, save one, at manipulative reduction, but have, instead, done the operation by arthrotomy in all instances.

---

* Read at the meeting of the American Orthopedic Association, Atlantic City, 1904.

As regards the manipulative method, I am sure that Lorenz told the whole truth when he stated that the obstacle to reduction was the narrowed part of the capsule just at the posterior and superior or superior part of the acetabular rim. If the opening, at this narrowed part, is big enough to permit the head to pass, reduction can be accomplished by manipulation, and may be maintained if the acetabulum is deep enough. I have in two instances done this, I know. In the 28 cases in which I have done arthrotomy, and in which I have explored the narrow part of the capsule by my finger, and so know its size and the strength of its walls, there has been but one case in which the passage of the head would have been possible. I am not too dogmatic when I say that no possible force could have put the femoral heads through the narrow part of the capsule in any of the other cases. One possibility, and 27 impossibilities!

Now what happens when attempts are made to accomplish this impossibility? Lorenz has reported plenty of fractures of the femur and one each of the pubis and of the ilium, and other operators have done the same.[1] Lorenz reports seven cases of paralysis out of 400 odd operations, but Taylor,[2] looking carefully for the condition, finds eleven cases in less than fifty operations, by various operators, including, I believe, Lorenz himself. While Taylor states that most of these cases recover, the uncertainty of the result is patent to all who have had the misfortune to injure a few major peripheral nerves. It certainly is an accident that can not be disregarded. My own contribution to the casualty list is the report of a case of Lorenz's own, of rupture of the capsule of the hip joint, distal to the constriction, and the thrusting of the femoral head out among the muscles of the thigh. While only one case was shown to have had this accident, still, from the similarity of the clinical conditions, I believe another had it, and it is not in the least impossible or improbable that it occurs in very many cases, especially in the class called "anterior transposition." Finally, on all sides one finds the absurdity of the term "bloodless" pointed out, and the reference to the lacerations of muscles, the extravasations of blood and hematomas. And last of all, Lorenz has reported one case of gangrene of the whole lower extremity.

These accidents must make any one who is not an enthusiast, or a special pleader, stop and think. One

hundred are perhaps to be considered fortunate if they get nothing.

In all seriousness I declare that the percentage of successes is not enough to warrant the risk, and I claim that the percentage of successes is not enough to justify the method apart from the risk. I am perfectly ready to subscribe to the satisfaction, for all parties, parents, patient and surgeon, which comes from a perfect anatomic and functional result, for I have experienced that satisfaction. But I deny that there can be any special satisfaction in the "anterior transposition," the result that has to be dubbed "good" in quotation marks, the result that still leaves a short limb and a limp, the result that in its failure may only suggest the quotation from Bret Harte, "He done his level best," as an excuse for the surgeon.

Ridlon quotes the earlier statistics of the operation for carcinoma of the breast, an ultimate mortality of 90 per cent. to excuse the 90 per cent. of failures to get anatomic results in congenital dislocations. But the 90 per cent. ultimate mortality in carcinoma of the breast was not satisfactory to surgeons, and methods had to be devised to lessen it. That they have been devised is shown by Kocher, who now quotes 42 per cent. of the cases sound three years after operation. The same dissatisfaction belongs to the results in congenital dislocation of the hip. We are bound to improve the methods of eliminating the risks, which are too many and too great and too awful. We have got to increase the number of cases in which the head is really and honestly put into the acetabulum, the cartilage of the head in actual contact with the cartilage of the socket. We are under the obligation of improving the methods for making this actual reposition permanent. In brief, we must improve in every particular the quality of the results we offer the people in these cases.

If we, as orthopedists, read what general surgeons teach and practice concerning the treatment of traumatic dislocations we shall see that they all deprecate the use of undue violence. Manipulation must be based on the most accurate knowledge of the mechanism of dislocation, and must be restricted to reduction without adding to the trauma. To accomplish this the dislocated bone must traverse, in its return, the path it made when it was displaced. Never must it be ground through a new path. If reduction is not possible by moderate force and in a reasonable time, an incision is imperative to permit the path to be cleared, the reduction to be done and the parts to be restored to the approximate anatomic relations.

No general surgeon to-day would countenance the use of extreme force in the treatment of an old unreduced traumatic dislocation. Moderate force, if it promises success or attains it, is advised, but extreme violence or prolonged efforts are wrong. In the light which an incision lets in otherwise insuperable obstacles are cleared away. In no instance of a recent or an old dislocation would a general surgeon attempt to jam a too large bone through a too small hole, and the passage of the femoral head through the constriction of the capsule in the case of the congenital hip dislocation, he would recognize, in the great majority of cases, as an impossibility.

If we turn to fractures, the advice and practice is the same. When the inside conditions of a fracture are such that satisfactory replacement of the fragments is impossible from the outside, the general surgeon makes an incision and deals with the fragments immediately.

1904.

I do not forget that as orthopedists, we are teaching much to the general surgeon, and that we shall probably teach more; but we must be careful that we do not, in this instance, abuse his confidence and so invite him to criticize; for the general surgeon knows that the trauma of an aseptic incision is practically nothing in contrast to the injuries recited as incidental to the forcible manipulative method. The incision is less than that required for an appendectomy, less than that required for a nephrotomy, less than that required for an intra-abdominal shortening of uterine ligaments, less than that required for a herniotomy, less than that required for a lithotomy, less than the admittedly often necessary exploratory celiotomy. If the general surgeon, the world over, would not balk at this little incision, why should we? Or, if those of us who do some general, as well as some orthopedic surgery, would not shy at incisions for some objects, why should we do so for other objects?

If I am not afraid to open the knee joint to take out a floating cartilage—and I am not afraid to do this—why should I be afraid to open the hip joint to clear away the obstacle between the acetabulum and the femoral head?

I really do not believe that the definiteness of that obstacle is appreciated or else this question would not be necessary. In the case of a child who had a congenitally dislocated hip, who had never walked and who died of pneumonia sequent to measles, I secured the os innominatum and the whole of the limb. Before the child's death I had tried a manipulative reposition, using carefully regulated force, and apparently had succeeded; that is, the head went with a hop and a click to some place near the acetabulum. A week after this, however, reluxation had occurred. I then definitely reduced through an incision, and while in the splint the fatal illness supervened. The necropsy of the hip joint showed that my incisional reposition had not been permanent, the femoral head was posterior and superior to the acetabulum and the incision in the capsule had healed so perfectly that it could not be found, so that the original local conditions were restored. Now with all of the tissues removed from the bones except the capsule, and able to get a thoroughly good hold of the parts and to guide my efforts by sight, I was still unable to put the femoral head into the acetabulum. At the present time I am fairly familiar with the feeling gained by thrusting the forefinger down into the contracted capsule and then through the isthmus. Why then should we subject a large number of hips to the forcible manipulation now in vogue? Why follow an inexact and vulnerating method which gives a small percentage of anatomic reductions, when we have at hand a simple and exact surgical method which will permit the reduction to be definitely accomplished in practically all the cases that are of suitable age?

Of course if we are to save these cases, irreducible by manipulation, from the risks of forcible manipulation, we must save all, for no one can tell, *a priori,* which case is to prove reducible and which is not; and that will mean that all congenitally dislocated hips shall be reduced by arthrotomy, so that the operator knows just what he is doing, does what he wishes, and does not do what he does not wish. Moreover, it means that all hips, in the suitable ages, shall be definitely reduced, the surgeon will actually put the two parts together, and, so far as the conformation of the parts permits, they will stay in that relation. If, however, the parts are so malformed that a reposition which shall be stable is not possible, there will be a reluxation or a subluxation, possibly an anterior one. This is just as likely to occur in the arthrotomy reductions as in the manipulative reductions, and no more likely. It will be a late result, and the mechanically inevitable result of preexistent anatomic conditions; it will not be the result of an inexact and incompetent method. I much prefer to be able to say to parents that I have put their child's bones together properly, but that the bones are too misshapen to remain together, than to have to say that I could not put them into any anatomic relation whatever.

Finally, by the arthrotomy method the patient will have been saved the exposure to paralysis, which comes at the rate of from 2 to 20 per cent of the cases; will have been spared the risk of a broken leg or pelvis; will not have had the contusion and lacerations of the muscles about the hip which result in ecchymoses and hematomas and possible gangrene; and will have been exposed only to the one danger of sepsis, the possibility of which should not be greater than, nor as great, as it is in clean appendectomies.

I do not see what is gained for the children by the present method of forcible manipulation except for that small proportion, 10 per cent., that gets the anatomic and functional perf[illegible]; and this result could be gained more easily [illegible]isk by the arthrotomy method, so that the [illegible]er cent. is not its at least, of chemical combinations, and how to intelligently combine drugs in order to obtain the best results without forming dangerous compounds.

PRESCRIPTIONS CONTAINING PHARMACEUTIC INCOMPATIBILITIES.

This heading is of particular importance to the pharmacist, as it is his duty to dispense as elegant and palatable preparations as possible.

As in the first group, only those prescriptions were classified which were particularly objectionable or unsightly in appearance, nauseating in taste or difficult to dispense as ordered. We obtained ten from the one store and three from the other. It has been frequently said that if a physician had to take some of the "potions" that he orders, there would be a radical change in modern prescription writing.

Every medical school should give a complete course in prescription dispensing in the pharmaceutic laboratory, as this knowledge would be of inestimable value not only in framing elegant combinations, but would be of especial service to the country practitioner who is compelled to compound his own medicine.

PRESCRIPTIONS CONTAINING THERAPEUTIC INCOMPATIBILITIES.

Only one prescription was found that was particularly antagonistic from a therapeutic standpoint, and this shows that the average medical student is more thoroughly trained in therapeutics than he is in pharmacology.

PRESCRIPTIONS CONTAINING SIX OR MORE INGREDIENTS.

Thirty-four in the one series and sixteen in the other contained six or more ingredients, and it was a noticeable fact that the majority of these prescriptions were written by a certain few physicians who had drifted into polypharmacy. It is pleasing to note that this tendency is gradually dying out, and we hope that the day is not far distant when the old "shotgun" prescriptions, of from twelve to fifty ingredients, will be framed as curiosities of by-gone days.

Another noteworthy fact is that these prescriptions are mostly written by the very old practitioners. If this improvement had only occurred years ago, homeopathy would not have gained its present foothold; then, again, the system of prescribing as used in our best hospitals is so designed as to use only single drugs or preparations, and to make these as elegant and palatable as possible—a good step in the right direction.

PRESCRIPTIONS CONTAINING FROM TWO TO FIVE INGREDIENTS.

This constitutes the great majority, almost three-fourths, of the prescriptions, and shows a great improvement over the prescription of a century ago, when it was the popular belief that the greater the number of ingredients the greater the chance of cure. This rule would apply where ignorance in diagnosis exists, as by this theory the greater the number of ingredients present the more likelihood of administering something that will be of service. A good example of this is the old Warburg's tincture; the original formula as directed by Dr. Warburg contained the old *"confectio damocratis."* This was a complex astringent confection containing opium, and originally had sixty-four ingredients, many of the constituents being unobtainable at the present day.

PRESCRIPTIONS CONTAINING ONE DRUG OR PREPARATION.

It is pleasing to state that the greater number of these prescriptions were written by our most able practitioners, men who are prominent in medical teaching, and while they do not represent quite one-fourth of the total number, this is not a bad showing.

PRESCRIPTIONS CONTAINING ONLY OFFICIAL PREPARATIONS.

Approximately one-half belonged to this group, and it will be noted the very slight variation in this respect in the two series. This is likewise encouraging, and may the day be not far distant when the number will be increased still more. A point of interest observed here was that the more educated the physician the greater the use of the United States Pharmacopeia.

PRESCRIPTIONS CONTAINING PROPRIETARY PREPARATIONS IN WHOLE OR PART.

One hundred and ninety-five of the one series and 164 of the other, about 36 per cent., contained proprietary preparations, or, in other words, more than one in three prescriptions.

This is a good showing, when we consider that the manufacturing chemists employ persuasive salesmen, who visit every physician's office at stated periods and present him with a liberal supply of their "ideal" preparations, which are always "superior to any other made," and which are usually combined by a "peculiar" chemical process that enhances their therapeutic activity.

PRESCRIPTIONS CONTAINING PATENT MEDICINES.

Only two of the prescriptions were for patent medicines, and one of these was written by an "osteopath," so that we are only responsible for one, and this was one too many. How any regularly qualified practitioner of medicine could so disgrace himself and his profession as to order patent medicines is beyond my comprehension.

PRESCRIPTIONS IN WHICH THE METRIC SYSTEM WAS EMPLOYED.

Only three of the one series and two of the other demonstrate the fact that the metric system is but little employed at the present time, and its use does not materially increase, as my own experience in the retail drug business for a number of years corroborates. One fact is observed, when a practitioner uses the metric system, he uses it exclusively. It is to be regretted that the profession does not adopt this system and use it exclusively, as it is simpler, more scientific and in every way preferable to our present system of weights and measures. The leading medical schools give their students a thorough training in this system, and teach them how to convert the various denominations into the English system, and vice versa, but after leaving the college halls this is all thrown aside.

PRESCRIPTIONS CONTAINING NON-OFFICIAL PREPARATIONS IN WHOLE OR PART.

In this group are classified prescriptions containing commonly used preparations which are not recognized by the United States Pharmacopeia, but which can be prepared by any pharmacist, such as elixir of iron, quinin and strychnin. In this group we have sixty in the one series and ninety-five in the other, showing considerable variation, a noteworthy feature being that the series that yielded a large number, thirty-four, of the polypharmacy type of prescription, yielded the small number, sixty, of this type, while the other series that yielded sixteen of the former yielded ninety-five of the latter. A proportionate comparison.

NUMBER OF PRESCRIPTIONS WRITTEN CORRECTLY.

The criticisms in prescription writing applied to the endings used in designating the drugs or preparations and the use of the proper official names as embodied in the inscription, and the proper phraseology as applicable to the subscription. As a rule, the prescriptions of the teaching class of practitioners were correctly written to a great extent, while those of some of the regular practitioners were carelessly written, and those of others showed a marked defect in the knowledge of prescription writing. This was especially noticeable among the prescriptions of the more recent graduates. Less than two-thirds were correctly written, and this is largely due to the deficient training in this important subject in the average medical school. Several of the prescriptions were written by a young practitioner who received the highest average among 400 men at a recent examination of the state medical board, yet every one of his prescriptions showed errors in writing and in combining drugs. This merely shows that his training was deficient in this important subject.

IMPORTANCE OF PROPER TRAINING IN THIS BRANCH OF MEDICINE.

Now, who is responsible for this deficiency? Is it the teacher, the means at his command and time allotted for teaching the subject, or the student, that is at fault? The teacher is often a physician, who has never received any practical pharmaceutic training other than the "smattering course" that he received as a medical student, and, as a rule, on account of limited training and lack of interest, he follows the same rut as his predecessor; as a consequence, the pharmaceutic laboratory is deficient in its equipment and very unattractive.

Because of these facts, officers and trustees consider this branch of medicine unimportant, and the student, not realizing the value of a pharmaceutic training, completes the course ignorant of its many valuable points, and usually not until he reaches the senior year and commences to prescribe does he fully realize his deficiency in the knowledge of the mode of preparation, appearance, administration and effects of combining drugs, the very ammunition he is to use in firing his gun of knowledge to combat disease. It is not, however, until as a physician, authorized to use blank and pencil, and brought face to face with the patient, that he most seriously and keenly feels the sting of his pharmaceutic ignorance; tries to formulate a palatable mixture and fails, expects to find a nice clear solution when he calls, only to find one with an unsightly and often dangerous precipitate. It is now after repeated failures that the horizon is filled with attractive-looking proprietary preparations, and these are substituted for the official drugs, because the label states that they are specific for the disease under consideration. As a result, this habit once established is continued through life.

Three of the above prescriptions were written by "osteopaths" and they all showed utter ignorance of the first principles of prescription writing. This should be a warning to us, because, if osteopaths should receive recognition in the various states they will attempt to prescribe medicines and to treat all diseases, not limiting themselves to their own particular methods. The medical profession should be aroused to this matter and take action before it is too late. In the past few months several scathing editorials have appeared in the daily press relative to the large number of incompetent practitioners who are turned out by our medical schools, and the state board suggests an investigation of the present methods of teaching and the adoption of a more comprehensive curriculum.

However, in looking over the examination results of the various state boards as compiled in the Aug. 13, 1904, number of THE JOURNAL of the American Medical Association, we find that the percentages of failures from the Philadelphia medical schools vary from none to 8.6 per cent. for the year 1903, and this was the most satisfactory showing of any state in the series, when one considers the number of students examined.

The total number of candidates examined in the thirty-seven states was 5.027. They represented 151 American colleges, 8 Canadian institutions, and there were some representatives of foreign schools. Of the whole number examined, 4,312 passed and 715 failed. The percentage of failure was 14.2, but of the Philadelphia students but 5.48 per cent. were found wanting. This was a lower percentage than was shown by any other state or by the outsiders. The percentage of failures from New York was 7.12; of Boston, 7.28; of Chicago, 8.18; of Washington, 18.84; of Baltimore, 22.70; of Louisville, 27.67; and of St. Louis, 32.67.

Another remarkable showing is, that of the 4,312 successful candidates, 9 per cent. were from the Philadelphia schools, and only 3.2 per cent. of the 715 failures can be charged to this city. These figures demonstrate conclusively that the medical training given by the Philadelphia schools is thorough and comprehensive.

Again, at the recent examination of a state medical board the following are two of the questions asked under materia medica:

1. Name the drug of which pilocarpin is the active principle, and give the dose of the tincture that would be equivalent to 1/20 grain of pilocarpin.

In the first place, there is no official tincture of pilocarpus, and hence no recognized tincture of definite strength, and the majority of our standard medical works do not mention any strength for the tincture, and those that do show a variation in strength, so that this question is unanswerable. Books like those of Remington, Caspari, Coblentz and United States Dispensatory on pharmacy, and of Shoemaker and Potter on materia medica, do not mention any strength for the tincture, and, granted that the strength was given, the yield of alkaloid varies from 0.25 to 2 per cent. in different lots of the drug, as all the books state; therefore, how in the world can a student answer such a question?

2. Give the dose of tincture of nux vomica equivalent to 1/30 grain of its principal alkaloid, and name two official preparations into which this active principle enters.

This is a more desirable question, but even here very few students can remember the strength of the tincture as indicated in the United States Pharmacopeia, and for the second portion of the question, a number of the students gave the salts of strychnin instead of the preparations asked for. After conversing with a number of the candidates as they came from the examination room, I found that not one answered these questions correctly.

If the medical boards desire less failures, let them ask: First, questions that can be answered; and, second, questions that when answered are of some practical value, and not unanswerable and unusual questions that no one could answer intelligently, even if they had access to the text-books. The object of state examining boards is to determine the fitness of candidates to practice medicine and surgery, and this can only be done by asking practical and useful questions, that every well-

NEUROFIBRILS.

The idea that the nerve-cell protoplasm has a fibrillary content dates back to the time of Max Schultze. Histologists were, however, in doubt about the matter until Apáthy, a Hungarian scientist, with the use of a difficult and complicated method, devised by himself, demonstrated the fibrils convincingly. The method of Apáthy, however, yielded very inconstant results, and, moreover, often failed entirely in the hands of other estigators. Beside, the method was applicable only e tissues of invertebrates, mammalian and other rtebrate tissues failing to respond to the stain. Apáthy, by his demonstrations before various anatomic societies, was nevertheless able to convince research workers in his field that the fibrils actually exist.

A search for a method which would stain the neurofibrils in human tissues was rewarded by the discovery by Bethe of a procedure which stains tolerably satisfactorily the fibrils in normal adult nerve cells. Bethe's method is also a difficult one, and one which involves the treatment of the tissues with strong reagents. It is limited further by its non-applicability to embryonic organs.

The methodology of the subject was soon further enriched by Ramón y Cajal and by Bielschowsky, each of whom invented an easy method of demonstrating the neurofibrils by silver impregnation. Each of these methods yields excellent results, and histologists have not yet fully decided as to which of the two methods is preferable. A great advantage consists in the fact that the silver methods permit of the staining of the neurofibrils at the time of their earliest appearance in embryonic tissues. The technic of the silver staining is comparatively simple, and some good work has already been done with it in researches dealing with the pathology of nerve cells.

Bethe has made some interesting observations on what he speaks of as the "primary stainability" of the neurofibrils with basic dyes like methylene blue, thionin or toluidin blue. By "primary stainability" he means the property of staining tissue in the fresh condition, or when it has been altered by dehydration only; he contrasts this primary stainability with the secondary stainability which exists after the tissue has been chemically altered, say by the action of some mordant. On staining nerve cells with methylene blue or toluidin blue, dyes which above most others exhibit neurotropic affinities, it is found that not only the tigroid masses of Nissl take the stain, but also the neurofibrils and sometimes the myelin sheath of medullated nerve fibers. In tissue dehydrated by alcohol, the myelin can be removed by treatment with xylol, and then only two substances remain which possess primary stainability. The use of toluidin blue as a staining reagent is especially to be recommended because it stains the neurofibrils metachromatically, of a different tint from that assumed by the tigroid substance.

Bethe has shown that certain reagents possess the power of destroying the primary stainability of the neurofibrils without removing the fibrils themselves from the nerve-cell protoplasm. Thus nitric acid or dilute solutions of the alkalies so change the neurofibrils that they no longer stain "primarily," though they can be stained by mordanting methods. This fact led Bethe to the idea that some substance responsible for the primary stainability of the fibrils enters into their chemical constitution normally, but can be easily split off from them. By further experimentation he found that the primary stainability of the neurofibrils can be destroyed by treatment with a dilute solution of hydrochloric acid in alcohol, though the Nissl bodies remain unchanged in their stainability by this process. The primary stainability of the latter can, however, be removed by treatment with a dilute aqueous solution of hydrochloric acid. Bethe concludes, therefore, that in each instance an acid substance, combined with the albuminous substratum, is the chemical constituent underlying the primary stainability. He therefore speaks of the "fibril acid" in one instance and of the "Nissl acid" in the other. Each acid is split from its attached albumin by hydrochloric acid; the free fibril acid is soluble in alcohol but insoluble in water; the free Nissl acid, on the contrary, is insoluble in alcohol but soluble in water. Ammonia dissolves out the Nissl acid easily, but has no effect on the fibril acid.

It is interesting that Bethe has succeeded already in obtaining small quantities of these acids in a comparatively pure state and has begun the study of their physical and chemical properties. The free fibril acid is an amorphous substance, almost colorless, of horny consistence, insoluble in water, chloroform, ether or in dilute mineral acid. It dissolves tolerably easily in alcohol, especially when the latter is acidified, and can be precipitated from alcoholic solution by sodium hydrate or potassium hydrate in the form of alkali salt. The potassium and sodium salts are very soluble in water, but the ammonia salt is insoluble in either alcohol or water.

The free fibril acid suspended in water stains intense violet in toluidin blue. The free acid does not yield the biuret reaction, and it is not yet certain whether it contains nitrogen or not. The substance must be obtained in much larger quantities than those hitherto available before more definite statements regarding its nature and chemical constitution dare be made. Bethe obtained only two centigrams of the substance from a whole kilogram of the spinal cord of the ox.

Inasmuch as the conduction of impulses by nerve fibers appears to depend on the integrity of the chemical compound on which the primary stainability of the neurofibrils depends, the extraordinary interest and importance of the fibril acid become at once apparent. Further research along these lines will be eagerly looked forward to by neurologists everywhere.

THERAPY OF EXOPHTHALMIC GOITER.

Although it is now ten years since Baumann isolated the active principle of the thyroid gland, and since Roos demonstrated that this iodin-containing body accomplished the chief functions of the thyroid, if not all of them, yet it has not to this day been settled whether thyroidin acts by neutralizing toxic products of metabolism or by furnishing some stimulus necessary for proper metabolism. Much evidence has accumulated, however, to lend support to the view that neutralization of toxic substances is an important function of the thyroid, whether its sole function or not. Of particular interest is the evidence secured through the successful treatment of exophthalmic goiter on principles suggested by the antitoxic theory of thyroid function. From the results of many experimental and clinical observations, it has been well established that the symptoms of exophthalmic goiter are largely due to a poisoning by products of thyroid metabolism, although the cause of this overproduction is still an unsolved problem. Thyroid products, therefore, although normally acting to neutralize toxic substances, are themselves toxic when not neutralized and present in sufficient quantities. If it were possible, therefore, to secure these toxic substances that the thyroid products normally neutralize, it might be possible to administer them to patients suffering from thyroid intoxication, and thus neutralize the excessive products of the thyroid. This is, of course, simply a reversal of the practice in the treatment of myxedema, in which disease the patient is presumably suffering from unneutralized products of metabolism, which can be neutralized by administering thyroid extract.

The first application of this idea to the treatment of exophthalmic goiter was probably by Ballet and Enriquez, and later independently by Lanz and by Burghart and Blumenthal. Material was secured by removing the thyroid from goats or dogs; when the blood of the animals had become saturated with toxic substances which should have been neutralized by the thyroid, and the animals were suffering from the consequent tetany or acute myxedema, they were killed and their blood secured for therapeutic purposes. Whether injected subcutaneously in the form of serum, or administered by mouth in the form of tablets of dry blood, favorable effects have been obtained by many independent and competent observers. Lanz has furthered popular use of this method of treatment by discovering that the milk of thyroidectomized goats contains the toxic materials, and as goats live for some time without their thyroids it is possible to have the patient take daily for several months one-half to one pint of such milk, with good results. As goat's milk becomes objectionable after some time, a preparation has been made by precipitating out the toxic materials and administering them in solid form; such a preparation is on the market in Germany.

The clinical course of exophthalmic goiter is so variable that one is justified in withholding an opinion as to the results of any particular method of treatment until very considerable numbers of cases have been followed for a long time. However, when clinicians of the reputation of Möbius and von Leyden go on record in favor of this method, which is furthermore founded on a scientific principle, it may be considered to be of no inconsiderable worth. Von Leyden has recently published an interesting clinical lecture on the topic,[1] in which he states that improvement is generally observed in three to four weeks, but the treatment must be followed for months and repeated at intervals according to the condition of the patient.

THE SERUM DIAGNOSIS OF TUBERCULOSIS.

While the use of the Widal reaction has become widespread in this country, and serum diagnosis has also been used to a considerable extent in dysentery and in summer complaint, its use in tuberculosis has been almost entirely neglected. Whether this is due to the technical difficulties which make this test more difficult than the Widal and allied reactions, or whether it is due to the fact that we are more apt to follow a German than a French example, is hard to say. It can not be denied, however, that in America this method of diagnosis has not been given an extended trial.

The matter was recently brought up by the originators of the test, Drs. Arloing and Courmont, at the Congress of Arts and Science in St. Louis, and a full description of the test with its drawbacks and difficulties was given.[2] As the authors point out, the sources of error may lie in the localization and evolution of the tuberculosis, or in the manner in which the cultures used for the test are developed. It is pointed out that advanced cases are the ones which most frequently do not give the reaction, and, on the other hand, very early cases, which may present no physical signs, do give it. For this reason many observers have been skeptical about the accuracy of the results reported by Arloing and Courmont, notwithstanding the fact that in a good many cases they have been able to control their clinical findings by autopsy. Then, again, in order that the test shall be a satisfactory one, it is necessary that the culture of the tubercle bacillus shall be in the form of a liquid homogeneous culture. Arloing and Courmont point out that it is quite difficult to obtain a good culture, and that some of those who have criticized their work have failed to follow closely their directions.

---

[1] Medizinische Klinik, Dec. 1, 1904.

[2] Boston Med. and Surg. Jour., vol. cli, No. 23, 1904.

In order to obtain satisfactory results with their method, it is necessary, in the first place, to have a homogeneous liquid culture, grown in bouillon containing from 4 to 6 per cent. of glycerin, from a luxuriant greasy growth on potato. Such a suspension of tubercle bacilli must be tested with a standard serum which is known to agglutinate, as well as with the serum to be tested. As agglutination only occurs in relatively low dilutions, these should be used, preferably one to five, one to ten and one to fifteen. The serum to be tested should be fresh, clear and sufficient in amount, and the test should be watched for from three to five hours after it is begun. A test should never be considered positive unless the tubes show complete lutination visible to the naked eye, and showing and subsequent clarification.

ng and Courmont have followed these directions ver 400 medical cases, with the following results: Where there was a positive clinical diagnosis of tuberculosis 87.9 per cent. gave the reaction, and 12.1 per cent. did not; in hospital cases with no clinical tuberculosis 34.6 per cent. gave a positive, and 65.4 per cent. a negative reaction; in apparently well persons 26.8 per cent. gave a positive, and 73.2 per cent. a negative reaction. In a smaller number of cases of surgical tuberculosis, over 73 per cent. of the cases gave a positive reaction. The writers also found that the fluids from tuberculous inflammatory lesions have the power of agglutinating tubercle bacilli, especially the serum from cases of tuberculous pleurisy and mild cases of tuberculous peritonitis. In the case of non-tubercular effusions no agglutination takes place.

With regard to the fact already noted, that in advanced cases no reaction may occur, the authors point out the similar lack of tuberculin reaction in many advanced cases. The lack of reaction may be due to great virulence on the part of the infecting tubercle bacillus, or to a lack of resistance on the part of the individual. The latter factor seems to be the more important, as the authors state that the development of the agglutinating power seems to require well-marked resistance on the part of the infected individual. The value of the test is both diagnostic and prognostic. It is diagnostically valuable on account of the fact that it occurs in the early stages of the disease, even in people who have neither symptoms nor physical signs. It is prognostically valuable in advanced cases, where a failure of the reaction indicates a lack of resistance, and renders the prognosis grave. The test has been confirmed by a number of observers, both in France and Germany, and though there are some who deny its value, it seems well worthy of a more extended trial.

EXPERIMENTAL SYPHILIS.

Metchnikoff and Roux, followed by Lassar and Neisser, have demonstrated conclusively, by numerous and diversified experiments, that syphilis may be transmitted by inoculation to chimpanzees and other apes. It has been found that in the chimpanzee the period of inoculation varies between twenty-two and thirty-seven days; and, furthermore, that the disease may be transmitted from chimpanzee to chimpanzee. This means that it now has become possible to subject the "virus" or "contagium" of syphilis to more penetrating investigations with the view to obtain some idea of its nature, and thus pave the way for its actual demonstration.

So far, minute study of the material known to contain the infectious agent of syphilis has not yielded any information—organisms have not been found in the scrapings and juices of chancres and other lesions in either man or anthropoid. The thought naturally suggested itself that the syphilitic virus might be filterable, like the virus or organisms of bovine peripneumonia, of foot-and-mouth disease, of yellow fever, etc. But the experiments of Klingmüller and Baermann[1] and of Metchnikoff and Roux[2] show that the cause of syphilis does not pass through filters that permit the passage of the organism of peripneumonia, while small known bacteria are held back. Hence the virus of syphilis does not seem to be filterable, whatever the reason for this may be.

Metchnikoff and Roux, then, show that the syphilitic virus completely loses its virulence when heated for one hour to 51 C. On the other hand, pure glycerin seemed to have no effect on the virus. They found, further, that the heated and the filtered inactive materials did not have the power to protect chimpanzees against virulent virus. From this result and from certain other considerations, Metchnikoff and Roux were led to believe that an attenuated virulent virus, suitable for the purposes of a vaccine, might perchance be obtained from animals with a relatively slight susceptibility to syphilis.

For this purpose, extensive studies of syphilis in lower forms of apes and of monkeys seemed indicated. and Metchnikoff and Roux as well as others have accumulated quite a number of observations anent syphilis in some of the catarrhine monkeys of the Old World. These observations are as yet, however, wholly preliminary and serve for orientation. Perchance, before long indications may be secured that will point out definitely the direction along which extensive experiments must be made. Undoubtedly, the renewed interest in syphilis caused by the demonstration of its transmissibility to apes and to monkeys sooner or later will lead to more light being thrown on the many obscure questions connected with its etiology.

PERITONITIS AS A COMPLICATION OF TONSILLITIS.

Peritonitis results most commonly by extension from adjacent disease, especially of the abdominal viscera. Less commonly it arises as a result of infection transmitted by way of the blood stream from some more or less remote point. The tonsils have been pointed out as possible sources of danger in this connection. The function of these glandular structures is involved in some obscurity. They are known to act as absorbents and also to take part in the production of lymphocytes. By reason of their exposed situation, they are often the seat of disease; and there is a considerable volume of evidence that they serve as portals of entry for various pathogenic micro-organisms, at times, without being themselves seriously involved. Thus there is a growing belief that the micrococcus that is supposed to be the cause of acute rheumatism gains access to the interior of the body by way of the tonsils, and it is equally probable that other infections are acquired through the same channel. A case illustrative of this view has recently been recorded by Dr. Hermann Künzel.[1] A cook, 18 years old, came under observation in an unconscious state and died in the course of three hours. Postmortem examination disclosed the existence of purulent peritonitis, no other source for which could be discovered than inflammation of both tonsils. In cultures from these, as well as from the peritoneal exudate, streptococcus pyogenes developed. In explanation of the course of events in this case it is suggested that a small amount of fluid present in the peritoneal cavity may have constituted a favorable medium for the development of the bacteria entering the circulation by way of the tonsils. In any event, these organs must be reckoned with as one of the portals of entry for a number of micro-organisms capable of causing peritonitis, and their implication in various morbid processes is, therefore, not lightly to be dismissed.

DR. FRANK P. FOSTER.

Last Saturday Dr. Frank P. Foster completed his twenty-fifth year as editor of the *New York Medical Journal*, and we wish to congratulate him on the event. During the quarter of a century vast strides have been made in medicine and in medical journalism, but Dr. Foster has always kept at the front. Always honorable, fair and square as a man, he has stood for the highest ideals in medical journalism, and has set an excellent example for other editors to follow. As far as we know, since Dr. Culbertson of the *Lancet-Clinic* and Dr. Shrady of the *Medical Record* have given up editorial work, Dr. Foster is the Nestor of medical editors in the United States. We wish him many more happy and prosperous years.

THE USE OF SALT.

The question of the dangers of food preservatives is not yet thoroughly settled. The elaborate tests by Dr. Wiley, it is reported, have left with him an unfavorable impression regarding their effects on the human digestion, but his mind is still open to conviction on the subject. One thing, however, is certain—from an economic point of view, the food resources of the world would be considerably lessened if the use of all preservative chemicals, including common salt, was discontinued. Certain French physicians have recently discussed at some length the effect of salt and the value of dechlorization in certain disorders, and it is claimed, by at least one authority, that the use of salt is generally hurtful to the human system. The amount of the substance that we really require would be obtained through our food without the process of artificial salting, he says, and the taste for salt is not innate but is acquired. It would be impossible to avoid ingesting a certain amount of chlorid of sodium in our food. It is one of the most widely distributed substances in Nature, but it seems going a little to extremes to say that a taste for it is purely an acquired one, and it is easy to conceive that the universal craving for salt, which is shared by man in common with many of the lower animals, indicates a real want, and that at times, at least, salt may be insufficiently supplied by an unseasoned diet. Like everything else, salt is liable to overuse, but this does not mean that it may not be sometimes too little used. We can not dispense with the use of salt, if only for economic reasons, and while it may be harmful in certain disorders, its usefulness to the average individual in health and to the population generally can not be questioned. It would be an interesting calculation how much the world's progress is due to salt, and how far our present civilization could really exist without this important food preservative.

THE ORIGIN OF PARASITISM.

The remarkable predilection shown by certain species of microbes for certain hosts, and the relative indifference of these parasites to other organisms, has long been the subject of zealous speculation and inquiry. Great as has been the advance in our knowledge of the underlying causes of natural immunity during the last few years, it can not be said that any final explanation is even yet in sight. It is, indeed, apparent that the ardent prosecution of studies into the germicidal and antitoxic qualities of immune sera has caused a temporary suspension of activity in other lines of investigation. The broader biologic aspects of natural immunity sometimes have been neglected. It may well happen that studies in plant pathology will be found to throw light on some of the questions of animal parasitism that have hitherto been shrouded in obscurity. For some time botanists have known much concerning the various modes by which parasitic fungi gain access to the interior of the host plant. Some enter through the stomata, some by piercing the walls of the epidermal cells or the guard cells of the stomata. Marshall Ward, in his study of the Bermuda lily disease, discovered the interesting fact that the fungus concerned (a species of *Botrytis*) effects its entrance into the host plant by secreting at the tip of the germ tube an enzyme which *softens the substance of the cell wall.* Quite recently Massee has brought out important facts concerning the influences that determine the attack of a specific host by a specific fungus. It is pointed out that while the spores of a parasitic fungus will germinate on the damp surface of the leaf of any plant, yet the germ tubes will enter the tissues and infect only the particular kind of plant on which the fungus is known to be parasitic. It is a legitimate inference from this fact that the tissues of the particular host possess a special and peculiar attraction for the parasite in question. This hypothesis has been tested experimentally, and it has been found that under certain circumstances positive chemotropism plays a prime part in inducing infection. Through the use of certain chemical substances shown to attract certain fungi, an otherwise immune host plant has been successfully infected. In other words, the entrance of a parasitic fungus into the tissues of a healthy plant depends, at least in some cases, on the presence of some positively chemotropic substance in the cells of the st. It is stated that a saprophytic fungus can be ually educated to become an active parasite for a n plant by introducing a positively chemotropic substance into the tissues of that plant. It is possible also by similar means to induce a specific parasitic fungus to invade a new host hitherto not attacked by this particular parasite. In this connection it has been pointed out that a remarkable coincidence exists between the behavior of fungus spores toward their host, and that of the pollen grains when placed on the stigmas of flowers of their own and of other species. The marked positive and negative chemotropic properties shown in the attraction of pollen tubes are apparently closely related to the similar manifestations of the germ tubes of parasitic fungi. The strict association of specific parasite and specific host may, perhaps, be explained on a similar chemotropic basis.

---

[1] Münchener med. Wochenschrift, Oct. 25, 1904, p. 1920.

THE FOOD VALUE OF ALCOHOL.

The question whether alcohol is a food or not will be answered in accordance with the individual point of view, especially as to the definition of what constitutes a food. Some argue that if, after ingestion, it is oxidized in the tissues, entering into their formation and repair and giving rise to heat and energy, it may be considered a food, whereas, if it be excreted unchanged it can not be thus classified. Different observers have reached divergent conclusions on the subject, and the explanation must be looked for, in part at least, in differences in method, and in part also in differences in conception of the character of a food. It has been shown that alcohol is oxidized in the animal body, although, at the same time, it interferes with metabolism or oxidation of other substances, as indicated by lessened absorption of oxygen, decline in body temperature, degeneration of albuminous tissues into fat and diminution in the amount of urea, uric acid, carbon dioxid and salts eliminated. This impairment of metabolism may be attributed, among other things, to interference with the oxygenating function of the red blood corpuscles, while the readiness with which the alcohol seizes on the oxygen in the tissues and thus robs the fixed elements of their proper share, results in arrest of decomposition at the stage of fat formation and so, as a whole, in prevention of tissue waste. With the object of determining the exact point at which alcohol begins to be eliminated as such and the amounts of the substances into which it is transformed in the body, Dr. W. H. Goddard[1] undertook a series of experimental observations on dogs in which alcohol was administered in progressively increasing amounts. It was found that when alcohol was administered to the amount of 1/750 part of the body-weight, a little more than 5 per cent. of that amount was excreted. No aldehyd or other derivatives were detected in the expired air, the urine, the blood, or in any part of the body after death, so that it may be concluded that nearly 95 per cent. was utilized as food. When double the amount of alcohol was administered a little more than 6 per cent. was excreted, while acetic aldehyd made its appearance in the expired air, although none could be detected in the urine or elsewhere in the body. Finally, when a large amount of alcohol was administered, rather more than 49 per cent. of alcohol or its equivalent was excreted, and hence was unutilized. Accordingly, Goddard comes to the conclusion that alcohol has a distinct food value when taken in small amounts, but when larger amounts are given it is in considerable part excreted from the body unchanged, while at the same time the unutilized excess interferes with the normal metabolism. Over and above the part that alcohol plays in the metabolic economy, consideration must be given also to its irritant effect on the mucous membrane of the digestive system, and the tissues of the liver, the heart and blood vessels, the kidneys, the nervous system, etc. In a word, therefore, alcohol in small (physiologic) doses may be made to subserve a useful purpose, while in large (toxic) doses it is calculated to do harm.

Medical News.

ILLINOIS.

Chicago.

Wood Sent to Jail.—Dr. N. News Wood, of Christian Hospital notoriety, was sentenced to ten days in jail for contempt of court, December 30, and in addition he was fined $100 and the "hospital" $250, for violation of an injunction restraining them from using the name of Dr. John B. Murphy in connection with the establishment.

Chicago's Health in 1904.—Dr. Arthur R. Reynolds, commissioner of health, reports that during the first eleven months of the year there had been a total of 23,959 deaths from all causes reported, with an annual death rate of 12.54 per thousand—as compared with a total of 25,999 and a rate of 15.15 per thousand during the corresponding period of 1903. Since then there has been a great increase of mortality and the total is swelled to 26,300 for the year 1904, with an annual rate of 13.61 per thousand. Still this is the lowest on record for the city and the lowest by a wide margin for any city of magnitude either in this country or abroad. The lowest previous death rate for Chicago was 13.88 for the year 1901—a year of remarkable healthfulness throughout the world. Only five of the important causes of death show any increase over the number of the previous year. Except deaths from the acute intestinal diseases, which were 16 more than in 1903, the causes showing increases were diseases over which sanitary effort and preventive medicines have as yet gained little or no control. These are: Apoplexy, 116; Bright's disease, 128; consumption, 234, and cancer, 59 more in the previous year. Smallpox, which more than on an epidem spread from repeated importatior has bee combated with such vigilance and efficiency that its mortality is only 30 as compared with 47 in 1903. This vigilance and efficiency, made possible by the city council's emergency appropriation, has prevented any panic or undue excitement from the continued presence of the disease—a presence which must last as long as smallpox remains so widespread throughout the country as it now is. A total of 2,614 fewer deaths among a population some 60,000 more than last year; a reduction of 1,224 deaths under 5 years of age, including 927 of children at the "milk-feeding period" of life; the best sanitary quality of the public water supply ever furnished, and as a consequence of the latter, a vanishing death rate from typhoid fever; a successful battle with frequent importations of smallpox—are among the features of the year on which Dr. Reynolds bases the claim that Chicago has maintained its record for highest degree of healthfulness among all the principal cities of the world—those having populations of more than 300,000 each.

---

[1] Lancet, Oct. 22, 1904, p. 113

MARYLAND.

Opening of Peninsula General Hospital.—The Peninsula General Hospital at Salisbury was opened formally December 28. There was a very large atendance of physicians of the eastern shore. The site is elevated, with fine view of Lake Humphrey and Wicomico River. The building cost $50,000 and was a present of Hon. William H. Jackson, M. C. It is of brick, stone and iron, four stories, with basement and sub-basement. The front is 35x46 feet, with two wings each 26x38 feet. In the sub-basement is the steam heating and electric light plant. In the basement is a chapel, embalming and autopsy morgue, dining-room, kitchen and laundry. The first floor contains writing room, physicians' and nurses' rooms, bath and toilet rooms, two wards and dispensary. The second and third floors contain private rooms and public wards, diet kitchens, and on the third floor is an operating room. There is an elevator. The president of the board has fitted up the building at an expense of $4,000, and the treasurer, Mr. W. R. Miller, has given an ambulance worth $500. The state appropriates $5,000 annually for the hospital. Addresses were delivered by Drs. Guy L. Hunner and H. O. Reik, Baltimore, and Dr. Joseph W. Hearn of Philadelphia. The medical staff consists of: Drs. F. M. Slemons, Louis W. Morris, J. McFadden Dick, E. W. Humphreys and George W. Todd, all of Salisbury; visiting medical staff. Dr. Joseph W. Hearn, Philadelphia, general surgeon; Dr. Howard A. Kelly, Baltimore, consultant: Dr. Guy L. Hunner, Baltimore, gynecologist; Dr. H. O. Reik, Baltimore, eye and ear specialist.

NEW YORK.

Measles in Buffalo.—Buffalo is suffering from an epidemic of measles. Forty to fifty cases of this disease are being reported daily to the Department of Health.

Personal.—Dr. A. W. Jayne of North Tonawanda has been appointed health physician to fill the term made vacant by Dr. Leanhardt, who has gone to Porto Rico.

Thrall Hospital.—The annual charity ball for the benefit of this institution, located at Middletown, was given Dec. 27, 1904. This hospital cares for many employes of the Ontario & Western Railroad and Mr. Fowler, president of the road, paid $250 for a ticket to show his appreciation.

Rabies in New York.—According to the last annual report of the State Department of Agriculture, rabies has been more prevalent in New York state than ever before. Rabies has been found to exist in the following counties: Sullivan, Ulster, Saratoga, Broome, Tioga, Tompkins and Chautauqua.

Impurities from Pulp Mills.—Recommendations have been awaiting the action of the legislature to restrain paper factories from polluting the waters of Lake Champlain and the streams in the vicinity with waste products. However, a new process for reclaiming these waste products has been invented in the meantime and is being used at Ausable Forks by which the water comes out perfectly clear, with all the impurities of the mill removed. Other companies expect to install plants, and it is hoped that there will be no further cause for complaint.

Safeguarding of Cities Against Impure Milk.—Health Commissioner Greene of Buffalo held a conference with State Commissioner Lewis and Commissioner Darlington in Albany concerning the safeguarding of cities against impure milk from the country. At present there is no inspection of dairies in the country and the cities have to rely to a great extent on the vigilance of the town health authorities to report dangerous conditions as to the source of the milk supply. It is proposed that New York City and Buffalo have their respective common councils authorize the appointment of the desired inspectors as city employes, the state health commissioner then to appoint them state inspectors without pay. The duties of such inspectors would be to make the rounds of all the dairies at frequent intervals to see that not only are the dairies in good sanitary condition and the utensils kept clean, but also that the cattle are kept in sanitary stables and that no milk from cows afflicted with tuberculosis or other diseases communicable to human beings be sent to the city. On the discovery of contagious disease in the family of a dairyman they are to suspend the sale of milk from this dairy until such time as the milk is beyond danger of infection.

New York City.

Personal.—Dr. Max Einhorn has been elected a corresponding member of "The Society of Physicians of Munich" (Aerztlicher Verein von München).

Beth Israel Hospital.—At the annual meeting of the directors of this institution it was reported that an additional building had been purchased at a cost of $71,000, adjoining the hospital. The total number of patients in the hospital during the year ended September 30 was 1,713; of these 88.5 per cent. were treated gratuitously. There is a surplus of $2,529 in the treasury.

Contagious Diseases.—There have been reported to the sanitary bureau for the week ended December 24, 347 cases of tuberculosis, with 143 deaths; 338 cases of diphtheria and croup, with 49 deaths; 227 cases of scarlet fever, with 15 deaths; 163 cases of measles, with 4 deaths; 60 cases of typhoid fever, with 17 deaths; 185 cases of varicella, and 17 deaths from cerebrospinal meningitis.

Good Collections for the Hospitals.—The general treasurer of the Hospital Saturday and Sunday Association reports an encouraging outlook for the collection now in progress. The returns from the church collections on Hospital Sunday showed large advances over last year. St. Thomas, for example, gave $3,300 more than last year, and the trades auxiliaries also show largely increased collections.

Presbyterian Hospital Deficit.—This hospital, one of the big four in the New York hospital group, reports a deficit of $72,963, which condition is by no means peculiar to this institution. It means that unless the public provides more generously for the hospitals they must come under municipal management. Mr. Frank Tucker, vice-president of the Provident Loan Society, has been urging the plan for raising a large endowment fund, the income to be used in supplementing the present incomes of the group of hospitals which find themselves in the same financial condition as the Presbyterian.

New Immigrant Hospital.—The United States government has planned to build a hospital for the reception of dangerous contagious diseases on an artificial island to be raised in the upper bay near Ellis Island. The land under water has already been purchased from the state of New Jersey and Congress has made available the sum of $150,000 for the construction of the island. The commissioner general of immigration will advertise for bids on the work in the immediate future. Some alarm has been expressed at what might seem to be the creation of a pest corral at the city's front door, but Dr. Doty, health officer of the port, did not think that there would be as much danger as under the present plan, and considered it much more fitting that the United States government should care for immigrants than the city of New York should continue to do so, even though the government was paying the city well for this service.

OHIO.

Ohio Valley Medical Association.—The executive committee of the Ohio Valley Medical Association has selected Henderson, Ky., as the place of the next annual meeting, which will take place Nov. 8-9, 1905. The president, Dr. J. W. Stone, will soon announce the standing committees.

Cincinnati Society for Medical Research.—At the regular meeting of the Cincinnati Society for Medical Research, held Dec. 22, 1904, the following papers were read: "The Sources of Tuberculous Infection in Cincinnati," Dr. B. F. Lyle; "Dystoma Hematoidium of the Bladder," with slides, Dr. A. Faller; "Histologic Findings in a Case of Diabetes Mellitus," Dr. J. E. Greiwe.

Cincinnati's Health in 1904.—The annual report of the health office shows that the number of deaths in Cincinnati during 1904 was 6,975, as against 6,201 for 1903, an increase of 774. The greatest mortality occurred in January, February and March. The number of patients visited by the city physicians during 1904 was 6,250, with a total number of visits of 12,486, as against 6,360 patients and 14,698 visits for 1903.

Highland County Medical Society.—The Highland County Medical Society, a branch of the Ohio State Medical Association, held an all-day session at Hillsboro, Ohio, on January 4, the president, Dr. J. T. Gibson, in the chair. The following papers were read: President's Address, Dr. J. T. Gibson, Lynchburg; "Laryngeal Tuberculosis," Dr. J. A. Thompson, Cincinnati; "Surgical Tuberculosis," Dr. J. C. Oliver, Cincinnati; "Prevention and Cure of Tuberculosis," B. F. Lyle, Cincinnati.

Typhoid Fever in Cincinnati.—Typhoid fever seems to be increasing in Cincinnati, according to the report of the Department of Health, 41 cases with 5 deaths having been reported *for the week ending December 23. The city seems to be* singularly free from other infections, there being reported but one case of measles with no deaths, 12 cases of diphtheria with no deaths, 10 cases of scarlet fever with no deaths, 2 cases of smallpox with no deaths, and a scattering of other infections.

Coroner's Report for Hamilton County.—The report of Dr. Walter B. Weaver, who has just finished his second and last year as coroner of Hamilton County, shows that his office has handled the largest number of cases in its history, a total of 823 for the year. These cases were divided as follows: Homicides, 37; *suicides*, 103. *Manner of suicide—By morphin*, 6; by carbolic acid, 25, a marked falling off from the previous year; by laudanum, 3; by cutting throat, 7; by shooting, 25; by hanging, 14, an increase; by falling in front of train, 1; by drowning, 6; by paris green, 8; by jumping from bridge, 1; by *jumping from* window, 1; by prussic acid, 1; by undetermined poison, 1. Accidents, 334. Nature of accident: Killed by steam railroad, 82; by electric railroad, 28. This is the smallest number of fatalities by electric railroad for a number of terms. Natural deaths, 334; alcoholism, 15, showing an increase over former reports. Total number of native born, 585; foreign born, 219; undetermined, 19; an excess of native born over foreign born and undetermined cases of 366. During Dr. Weaver's first term, 1903, the homicides were 30; suicides, 95; street car cases, 42; steam car, 89; natural deaths, 303; miscellaneous accidents, 223. At the beginning of the new year Dr. Otis Cameron formally assumed the office of coroner of Hamilton County. Dr. Cameron is not new to his duties, as he has occupied the office of *deputy coroner for several years during* the régime of Dr. Walter B. Weaver. Dr. Oliver Coe, who has served as receiving physician to the Cincinnati Hospital for a number of years, has been selected as deputy coroner.

PENNSYLVANIA.

Personal.—Drs. L. M. Frankhouser and Oan J. Thompson have been elected president and secretary, respectively, of the staff of the *Society for the Aid of Indigent Consumptives* of Reading and Berks County.

Physician Injured.—Dr. Frederick W. Van Buskirk, Pottstown, while on a visit to Philadelphia, December 30, fell on an icy pavement and sustained a fracture of both arms at the elbow *joint*. He was treated in the German Hospital.

Philadelphia.

Webster in Philadelphia.—Dr. J. Clarence Webster, Chicago, read a paper before the Philadelphia Obstetrical Society, December 5, on "Fibroid Tumors of the Uterus," and was afterward the guest of honor at a reception given by Dr. Richard C. Norris at his residence.

Hughes Memorial.—*In perpetuation* of the memory of Dr. Daniel E. Hughes, who served as chief physician of the Philadelphia Hospital for 12 years, a bronze tablet was unveiled on the wall of the main entrance to the hospital with appropriate ceremonies, December 27. The memorial was secured by subscriptions from admirers and friends, which were largely secured by the kindly efforts of the *Philadelphia Press*.

Dinner to Dr. Chapin.—In an item of news in The Journal, December 10, 1904, page 1798, the *presentation of an oil painting* of Dr. Chapin was credited to the members of the staff and the board of trustees. We are informed that there were 125 subscribers to the fund, which included, beside those *mentioned* above, a large number of physicians connected with hospitals for the insane, the managers of *the hospitals with which* Dr. Chapin is connected, and of other hospitals, etc.

Decreasing Marriages.—During 1904 there has been a decided falling off in the marriages in this city, as the figures from the marriage license office indicate. During 1903, 13,091 marriage licenses were issued. During the present year only 12,190 were issued, a decrease of 901. These figures, however, were given before the close of the year; therefore, by adding 100 more to the list of 1904 there still would be a *decrease of* 801. The reason for this falling off in the number of marriage licenses the officials believe is due to the publication of the *license list*. This leads, they say, young people who wish to avoid publicity to go to New York, Wilmington and the surrounding counties in the state where no publication is made.

Antitoxin in Diphtheria.—From the study of the cases of diphtheria recently admitted to the Municipal Hospital the *fact* is disclosed that there is marked *indifference* in many quarters as to the value of antitoxin in the treatment of the disease. Of 147 cases admitted to the hospital during September and October not one had received antitoxin before admission. All diphtheria patients admitted to the hospital are *immediately given antitoxin*. The effect of the measure is demonstrated by the following figures: Of 7 cases admitted within twenty-four hours of the initial illness all recovered; of 51 admitted during the second day of the disease 3 (all laryngeal cases) died; of 29 admitted during the third day 3 died; of 25 admitted *during the fourth day* 6 died; of 13 admitted during the fifth day 2 died; of 8 admitted during the sixth day 2 died; of 5 admitted during the seventh day 3 died; of 9 admitted on and after the eighth day of the disease 2 died. In other words, of 87 cases admitted on or before the third day of the disease only 6 died, *giving a mortality of 6.88 per cent.*, while of 60 cases admitted after the third day 15, or 25 per cent., died.

GENERAL.

Missouri Valley Medical Society.—The semi-annual meeting *of the Medical Society of the Missouri Valley* will be held in Kansas City March 23, 1905. An invitation has been extended to the presidents of the state associations within the territory embraced by the Missouri Valley and to the profession in general, and an interesting and profitable meeting is expected.

Southern Medical College Association.—The Southern Medical College Association has elected the following officers: President, Dr. Christopher Tompkins, Richmond, Va.; vice-president, Dr. J. C. LeGrande, Birmingham, Ala.; secretary, Dr. G. C. Savage, Nashville, Tenn.; executive committeee, Drs. J. A. Cain, Nashville; *Charles Rosser, Dallas, Texas, and* W. B. Rogers, Memphis, Tenn.

American Association for the Advancement of Science.—The fifty-fourth meeting of the American Association for the advancement of Science was held at the University of Pennsylvania, December 27-30. *Beside the ten sections of the* American Association, thirty affiliated scientific societies also held their annual meeting. This is the third time the association has met in Philadelphia.

National Association for the Study and Prevention of Tuberculosis.—The first *annual meeting of this association* will be held in Washington, D. C., May 18-19, 1905. There will be three divisions of the work—a sociologic, under the chairmanship of Mr. Homer Folks, New York City; a pathologic and bacteriologic, under the chairmanship of Dr. H. M. Bracken, St. Paul, and a clinical and climatologic division, with Dr. Norman Bridge, Los Angeles, as chairman.

One Hundred Years of Publishing.—The firm of William Wood & Co. of New York has just celebrated its hundredth anniversary and to commemorate it has issued a neat little book entitled "One Hundred Years of Publishing," which gives a history of the firm from its earliest beginning to the present day. With the exception of the Methodist Book Concern, *this is the oldest publishing firm in New York. A most* interesting account is *given* of the various buildings occupied by the firm and of the books and periodicals published by them. The business was founded early in 1804 by Samuel Wood, grandfather of the present senior partner of the firm, and his portrait forms the frontispiece. The first publication was a little primer called "The Young Child's A. B, C, or First Book," and a facsimile of the title page of this is reproduced. In 1810 Samuel Wood moved into a *larger store and took into partnership* two of his sons. In 1817 another move was made and also another son, William Wood, admitted to partnership. The business by this time had increased from the original trade in miscellaneous and second-hand books to the publication and *general sale*. both wholesale and retail, of books and general stationery. From the time of his admission to the firm William Wood was especially interested in medical works, and by his influence particular attention was *paid to* this class of publications. In 1836 Samuel S. and William

Wood bought out the interests of their father, Samuel Wood, and he retired from business. Samuel Wood died in 1844. In 1856 the firm again moved, this time to 389 Broadway. In 1861 Samuel S. Wood died, and for over a year William Wood conducted the business under his own name, moving to 61 Walker street. Soon after he took into partnership his son, William H. S. Wood, the present head of the house. The style William Wood & Co. was then adopted and has since been retained. From the time of his admission to the firm William H. S. Wood advocated further specialization in the direction of medical publications, and in 1866 the first number of the *Medical Record* was published. Various other medical and pharmaceutical journals have also been published by this house. The firm at the present time is composed of William H. S. Wood and his three sons, whose portraits appear in the book.

CANADA.

Toronto General Hospital.—The total number of patients treated at the Toronto General Hospital during the official year past was 3,825. Of these 2,191 were males and 1,634 were females. On Dec. 31, 1904, there were 276 patients in the wards.

Smallpox Statistics in Montreal.—Dr. Laberge, the health officer of Montreal, considers that the smallpox statistics for that city for the past few years is a fine illustration of the saying, "An ounce of prevention is worth a pound of cure." In 1885 the great epidemic carried off 3,164 people. In 1886 there were only ten deaths. From 1886 to 1896 not a death was reported. In 1897 there were 12 deaths, two in 1898, none in 1899, 10 in 1900, 2 in 1901, 10 in 1902, and 2 in 1903.

Pauper Immigration in British Columbia.—Dr. P. H. Bryce, chief medical health officer of the department of the interior at Ottawa, has been for some time in British Columbia securing statistics regarding the entry of diseased and pauper immigrants into Canada by way of British Columbia. The inspection is due to the report that diseased immigrants are getting into Canada by way of Puget Sound ports. There is no fear of European immigrants of the diseased class, who come direct, of getting into Canada via the United States, as the laws are sufficiently rigid in that country, but the government is investigating how far it can proceed with the inspection against the American border cities.

Dr. Osler in Toronto.—The last week of 1904 may well be handed down in the medical history of Toronto as "Osler" week, for Dr. Osler was there all week and, of course, was lionized. On the afternoon of Tuesday, Dec. 27, a reception was held in the new medical buildings by Dean and Mrs. Reeve for the purpose of giving the medical fraternity and their wives an opportunity of meeting Dr. Osler. On the following evening Dr. A. McPhedran, professor of medicine in the university, was at home to Dr. Osler and his medical friends, several being present from a distance from various parts of Ontario. On the afternoon of the following day Dr. Osler formally opened the new home of the Ontario Medical Library Association. This building, which has been recently acquired as a permanent home for this association, is situated in a convenient part of the city. To this library home Dr. Osler contributed $1,000, as well as making a large donation of books, formerly the property of his old preceptor, Dr. Bovel. Dr. Osler was further entertained by the Canadian Club and the Trinity Old Boys' Association.

FOREIGN.

Bubonic Plague at Aden.—From October 26 to November 25 the public health reports state that 21 cases of plague and 9 deaths from that disease were reported from Aden.

Senator Festschrift.—The *Festschrift*, presented to Senator on his seventieth birthday, is a volume of 460 pages, containing thirty works by his former or present pupils. It is published by A. Hirschwald of Berlin.

Zeitschrift f. Experimentelle Pathologie und Therapie.—This new medical periodical is a companion to the *Zeitschrift f. klinische Medizin*, being published in the same form and by the same publisher as the latter. The editorial staff comprises Brieger and Kraus of Berlin, Hering of Prague and Paltauf of Vienna.

Le Radium.—This is the name of a new semi-monthly medical journal just founded at Paris by a company including D'Arsonval, Blondlot, Becquerel, Beclère, Danysz, Oudin and Curie. J. Danne is the secretary, and Masson, 120 boul. Saint-Germain, is the publisher.

Honors for Ingegnieros.—Dr. J. Ingegnieros, professor of nervous and mental diseases at Buenos Ayres, has been awarded the prize offered by the medical faculty for the best scientific work published in the Argentine Republic during 1902-3. His friends gave him a banquet on the occasion. His works on nervous pathology are frequently quoted. Among the latest are articles on the hysteric laugh and the physiologic mechanism of musical language.

New Home for the Semaine Medicale.—The *Semaine Medicale* of Paris enters on its twenty-fifth year in new quarters, having recently moved to the building erected for a residence by the wealthy painter, Munkaczy. The artistic and palatial interior is in marked contrast to the popular conception of an editorial sanctum. The journal occupies the entire building, the editorial sanctum being a hall nearly 50 feet long by 26 wide, richly decorated with carvings, etc., in the renaissance style. The issue for December 14 gives several views of the interior of the new home. They suggest that the office boy will not have much time for his dime novels if he attempts to keep the carvings dusted.

The Don Quixote Tercentennial.—During January will be celebrated the three hundredth anniversary of the publication of *Don Quixote*, and our Spanish exchanges are devoting much space to the medical references to be found therein. The *British Medical Journal*, December 10, remarks that *Don Quixote* may be considered as a study of madness from its predisposing causes to its complete development. The contagion of insanity is shown in its effect on Sancho Panza, and the various efforts to divert the Knight of the Sorrowful Countenance from his exalted ideas indicate that Cervantes had a clear conception of the value of psychic treatment. He mildly satirizes the medical men of his day and makes frequent reference to various drugs and to the value of hygienic living.

Seaside Public Sanatorium.—The Sanatorium Umberto I, for the consumptive poor, erected at Leghorn, Italy, was formally inaugurated in December. Queirolo of Pisa, in the opening address, commented on the modern method of treating tuberculosis, which is to fortify the organism, to renew its energies and to stimulate its tissues to more active reactions. This is best realized at the seashore where the pure, ozonized air, the intense sunlight and the iodized emanations combined with nourishing food supply the elements needed for the struggle with the disease. The air of the Italian coast is a medicated, tonic and stimulant air, while the mildness of the climate and the great uniformity of the temperature are valuable points of superiority. He protested against the saying that "the Italian coast is the flower-strewn tomb for the consumptives of Germany." He also protested against the assumption that the mountains are better than the Mediterranean for tuberculosis, presenting arguments in favor of the seaside sanatoria.

Russian Physicians at Harbin.—Letters from Russian physicians at Harbin state that 32,000 wounded were received from the battles during the last four days of September. During the first weeks in October forty to fifty trains of cars loaded with wounded were always waiting at the station to be gradually emptied. There is a great difference now between the course of the wounds and those observed during the warm weather, the complications being much more serious and frequent. The wounded are not received until eight to twelve days after the injury. The first-aid dressings are, therefore, left unchanged too long, and during the colder weather the soldiers are dirtier and infection of the wounds occurs more frequently. Another reason for the higher morbidity is that the Japanese are using larger bullets with a comparatively soft copper mantle instead of the nickel steel mantles they used at first. During the warm weather scarcely any one succumbed in the hospitals to the effects of his wounds, but the outlook is different now, although the tidal wave of wounded has subsided. Fully 20,000 were given shelter in Harbin, the Red Cross and similar institutions caring for only 2,000, while all the rest were in the hands of the military surgeons. The writer of the letter from which we quote the above states that so much is said, written, printed and telegraphed about the work of the Red Cross that one is apt to forget that scarcely more than 10 to 12 per cent. of all the wounded pass through its hands. The care in the Red Cross hospitals averages better than in the military hospitals, but at an incomparably greater expense. There is plenty of good food in the army hospitals, and in every respect they hold their own in comparison, while in cleanliness they surpass the Red Cross. In the military hospital in his charge there are accommodations for 630 patients, with a surgical force of four, one of whom is a gynecologist. The letters written home by the recently deceased Dr. B. Böttcher have been published in book form under the title, "With the Red Cross in the Far East."

LONDON LETTER.

The Motor Ambulance.

At the headquarters of the army medical corps an interesting series of trials was made to show that the motor car may be useful as an ambulance, for the generation of electricity, for the lighting of field hospitals, for the manufacture of ice, for the sterilization of water and for many other useful purposes in the field. On the snowclad square of the barracks the motor stood covered with armored plating one-quarter of an inch thick, forming an effectual protection against bullets. The driver was protected by shields. Within the shelter sat two Red Cross men. The idea is that the motor could advance to where the wounded lie, even in the line of fire. Then stationary armor flaps would be opened and complete protection afforded to the wounded and dressers while first aid is being rendered. After this they would be rapidly sent to the rear. The trials were watched by Sir William Taylor, director general of the army medical corps, who expressed his satisfaction.

The Health of the Navy.

A blue book containing a statistical report of the health of the navy for 1903 has been issued. On the whole the returns are very satisfactory. With an increase of 3,500 men as compared with the previous year there are decreases in the cases of illness, invalidings and deaths. The numbers are respectively 85,735, 2,478 and 433, in comparison with 85,769, 2,985 and 590 in 1902. The aggregate number of cases of disease and injury for the year furnishes a ratio of 831.57 per 1,000, which shows a decrease of 29.56 per 1,000 as compared with 1902, and of 48.6 when contrasted with the average of the last six years. The invaliding ratio—namely, 24.03 per 1,000—shows a decrease of 5.93 as compared with 1902, and also a decrease of 6.94 in comparison with the average for the last six years. The highest invaliding rate was on the North American and West Indian stations. As regards the death rate, the ratio per 1,000 was 4.19, showing a decrease of 1.73 as compared with 1902, also a decrease of 1.49 as compared with the average of the last six years. The highest death rate occurred on the East Indian station. The total death rate, 4.19, is the lowest recorded since 1856. The death rate from disease alone was 2.79 per 1,000, which is .72 less than in the previous year.

The Milk Supply of Towns.

The question of the milk supply of towns has been considerably discussed of late. It is certain that the conditions of many dairies and the manner of transport of milk leave much to be desired. How to obtain "clean milk" instead of that too often supplied containing much dirt and therefore swarming with germs is the problem. In a paper on "The Management of the Milk Supply of Towns," read before the Charity Organization Society, Dr. Edmund Cautley said that it is a matter of difficulty and uncertainty for the rich and almost one of impossibility for the poor to obtain satisfactory milk in large towns. There is a lack of efficient control. The local authority in London, for example, has due control over the production of milk in its district, but none whatever over that brought from the country. Consequently milk is drunk in London which has been declared unfit for sale in the country or in other large towns. It is difficult for the local authority to ascertain the exact source of the milk supply of any particular vendor. Even when this has been done it is only with considerable trouble and after the loss of a dangerous amount of time that the local authority, by means of a cumbrous legal process, can stop the delivery in its district of infected milk from a farm. Moreover, the same milk may still be delivered in an adjacent district. With regard to the bacteriologic impurity of milk from samples of milk bought in London, Dr. Cautley found from 3,000,000 to 30,000,000 of microbes in each teaspoonful. Though most of these microbes were harmless, it is by no means uncommon to find dangerous ones. In 14 per cent. of London milk the tubercle bacillus has been found.

The Expedition of the Liverpool School of Tropical Medicine to the Congo.

A most important and interesting report has been sent from the Congo by the expedition dispatched by the Liverpool School of Tropical Medicine. A state steamer was placed at the disposal of the expedition by the government, enabling it to make fairly complete observations of the spread and distribution of sleeping sickness along the Congo River from the "Pool" to the "Falls"—a distance of nearly 1,000 miles. A disease the nature of which has previously been unrecognized was found to occur amongst the state's cattle. Its pathogenic agent was shown to be a trypanosome, the species of which is yet undetermined. Sleeping sickness is a terrible scourge, especially amongst the river tribes. It is obvious that the disease has spread in the Congo in recent years along the lines of communication, that is, along the rivers. Declared cases of sleeping sickness are easily recognized, but the trypanosome may be present in the blood for months and even years while the patient remains in apparent health. It is believed that palpation of the cervical glands is an excellent clinical method of detecting an infected person. When many of these glands were enlarged to above 1.5 by 1 cm., other causes being absent, trypanosomes were generally found in the drop of fluid obtained by aspirating a gland with a hypodermic syringe. As a rule simultaneous examination of the blood gave a negative result.

The Medical Profession and the Teaching of Hygiene.

A petition signed by 14,718 medical practitioners has been directed to the central educational authorities of the United Kingdom in which each local authority is urged to consider whether it would not be possible to include in the curricula of public elementary schools and to encourage in the secondary schools such teaching as may lead all children to appreciate at their true value bodily conditions as regards cleanliness, pure air, food, drink, etc. The petitioners consider that such instruction should be placed among the subjects of compulsory education and be given at an earlier age than at present. They point out the conditions which prevail in Canada, Australia and America for such teaching. A syllabus of suggested courses in the teaching of hygiene and temperance has been drawn up and adapted to the different ages of the children in elementary schools, special attention being drawn to the deleterious effects of alcohol.

Correspondence.

The Propriety, Indications and Methods for the Termination of Pregnancy.

Boston, Dec. 20, 1904.

To the Editor:—In reply to the enclosed* letter: In my paper I have stated what are now generally considered to be the indications for the termination of pregnancy in properly selected cases, so that it is unnecessary for me to review the subject again here. As I have nothing to conceal in this matter, however, and as every operation that I have performed has been done after mature deliberation and consultation with reputable men, I have made a brief report of each case for publication.

1. Mrs. E. F. B., Oct. 15, 1900; seen in consultation with Dr. A. A. Cliff; patient had also been seen by Dr. L. A. Cliff; young married woman with extreme exhaustion from constant vomiting; she and husband both desirous of children and to have pregnancy continued if possible. Condition extreme and recovery considered doubtful even with operation. Adherent retroversion. Pregnant about six weeks. Curettage under primary anesthesia.

2. Mrs. F. W. H., Nov. 26, 1900; was referred to me by Dr. G. H. M. Rowe, superintendent of the Boston City Hospital, and was seen in consultation with Dr. S. W. Kelley, ex-president of the East Middlesex District Branch of the Massachusetts Medical Society. First pregnancy about six years before, and patient and her husband were anxious for other children. Second pregnancy at two months; critical condition from continued vomiting. At second consultation uterus curetted under very light anesthesia.

3. Mrs. E. R. F., wife of a physician; first seen July 11, 1903; about four weeks pregnant, with a mild degree of pelvic inflammation, and with marked degree of emaciation and general exhaustion. No improvement in condition under treat-

---

* Editor's Note: This letter is a reply to that of Dr. Cattell in The Journal, Dec. 31, 1904. We sent a copy of Dr. Cattell's letter to Dr. Higgins December 9, asking him to send at once any reply that he wished to make. After waiting two weeks we published Dr. Cattell's letter in the issue of December 31, which went to press December 28. Dr. Higgins' letter was received December 30.

ment and restriction to bed. Husband suggesting that pregnancy be ended, I asked Dr. Charles M. Green, associate professor of obstetrics and clinical gynecology at the Harvard Medical School, to see the patient with me. Dr. Green saw the patient in consultation August 17, and advised operation, which was done, Dr. L. R. G. Crandon assisting.

4. Mrs. C. N. C., Sept. 29, 1904; seen in consultation with Dr. Edward T. Twitchell. Patient had been in a critical condition from previous illness and had been cautioned against immediate risk of pregnancy. I was asked to see the patient immediately early in the morning, because of her rapid decline from vomiting. Patient was in a private hospital, and operating table, etc., had been prepared for operation, but to save time and the patient's strength, she was quickly curetted on the bed under primary anesthesia. Vomiting ceased, but patient died in about twenty-four hours of exhaustion.

5. Mrs. G. H. H., wife of a physician; seen in consultation with her husband and Dr. J. B. Lyons; was referred to me by Dr. F. C. Shattuck, professor of clinical medicine at the Harvard Medical School. Patient was first seen on Nov. 20, 1903, and was in a very critical condition from continued vomiting, but operative relief was very much opposed and at first refused by the patient and her family. Three days later I was again summoned and performed the operation, assisted by Dr. Furrer. Recovery was very slow and during the convalescence Dr. Shattuck saw the case in consultation with me.

6. Mrs. E. M. G., Dec. 30, 1903; seen in consultation with Dr. Francis Magurn; about three and a half months pregnant; failing rapidly from inability to take and retain food. The cervix was dilated and applications made with the hope of obtaining some relief. Dr. E. M. Plummer, the laryngologist, saw the patient several times with the hope of relieving throat symptoms, which it was thought might be interfering with taking food. Dr. J. A. McDonald also saw the patient twice at the request of the family, and finally advised an immediate operation to save her life, although at first he was inclined to doubt the necessity for it, as he had never seen a similar case in many years' experience. Operation was performed on January 12, and Dr. Freeman Allen was asked to go out of town in the night to etherize, because of the patient's urgent condition and that it was impossible to empty the uterus at this period of pregnancy under primary anesthesia. There was improvement for a short time after the operation, but other symptoms developed, delirium, blindness, cerebral retraction, etc., and death in about seven weeks. It seemed probable that the cause was a tubercular meningitis.

7. Mrs. F. W. H.; same patient as No. 2. Anxious for more children and about two years before consulted Dr. Kelley to see if he considered it safe for her to become pregnant again. March 17, 1904, Dr. Kelley telephoned me that Mrs. H. was in a dangerous condition from pernicious vomiting of pregnancy, and asked me to see the case with him. After consultation with Dr. Kelley immediate operation was done to relieve the patient.

8. Mrs. G. H. H.; same patient as No. 5, and seen in consultation as before, Sept. 17, 1904. Subacute appendicitis complicating pregnancy; very severe vomiting and most distressing thirst, retaining no food and practically no liquid. As some form of relief was fast becoming imperative, it was debated whether the appendix should be removed or the uterus emptied. The latter seemed the safer procedure, inasmuch as removal of the appendix might not relieve the symptoms, and she was in no condition to undergo both.

9. Mrs. R. K.: first seen Sept. 16, 1904, with Dr. Francis J. Ford. About four months pregnant: last confinement about one year before, which she barely survived, owing to cardiac and renal disease. When first seen she was beginning to complain of shortness of breath, inability to walk much or to go up stairs. The question of interference was raised, but it was thought that under rest and care she might reach the viable period. She grew worse, however, and on October 18, after a bad night with pain, increasing dyspnea and cyanosis, labor was induced.

The above include all of my cases done before the viable period. There are also some cases in which premature labor was induced after the seventh month, but I see no necessity for reporting these at this time. FRANK A. HIGGINS.

Enuresis in Children.

NEW YORK, Dec. 30, 1904.

To the Editor:—The editorial in THE JOURNAL of Dec. 24, 1904, and the previous comments on the paper of Dr. J. C. Rey, on the subject of enuresis in children, both seem to leave Hamlet out of the play. Preputial adhesions are so predominantly the cause for enuresis, or at least the precipitating factor, that they might well be referred to in Celtic capitals in "scarehead" proportions in the text of contributions on the subject. Particularly in girls is enuresis dependent on preputial adhesions. It is one of the curiosities of medical literature that the subject of preputial adhesions is dealt with chiefly in reference to boys, while, as a matter of fact, girls need circumcision more frequently than boys for the reason that they are more subject to preputial adhesions than boys are. The more impressionable nervous system of girls responds to the irritation more quickly and more extensively than it does in boys. If any woman physician struggling for practice wishes to get some brilliant results, and fame ahead of time, let her take up the subject of circumcision in girls. Concerning the single symptom of enuresis, it will commonly disappear on the day on which circumcision is performed, and will not reappear. In older patients who have developed an enuresis habit, in spite of applications of moral suasion, belladonna, the back of a hair brush, and Eddyism, there is a tendency for occasional enuresis after the cause has been removed, but the results of circumcision in the cases that are dependent on preputial adhesions are so prompt, as a rule, that we are not left in any doubt about the character of the influence that had been at work. ROBERT T. MORRIS.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

QUALITATIVE SUGAR REACTION IN THE URINE.

To the Editor:—Anent your editorial in THE JOURNAL, Dec. 10, 1904, on the above subject, permit me to call you attention to the method advocated in inclosed reprint. It is much simpler, it is no more time consuming, and it is more certain (in small percentages) than is fermentation, and it is certainly much less trouble. W. C. RILEY.

ANSWER.—The method recommended by Dr. Riley is as follows: "Take equal parts of the suspected fluid and Fehling's, cold, mix thoroughly and set aside. Any urine containing .05 per cent. or more glucose will react, giving a yellow precipitate in the course of 24 hours or less, according to the amount of glucose present and the room temperature." In connection with Dr. Riley's comment a brief historical review of our knowledge of the reduction of copper salts by sugar in the urine may be of interest. The fact that salts of copper, especially blue vitriol, are reduced in alkalin solution by glucose with separation of red cuprous oxid was first discovered by Becquerel; the reaction was not studied carefully, however, until 1841, when at Mitscherlich's suggestion Trommer looked into the matter and demonstrated the extraordinary delicacy of the reaction which has since borne his name. Müller and Hagen showed later that under favorable conditions as little glucose as 0.0000833 gram in ice water could be easily and certainly demonstrated. On applying Tommer's test or other copper tests to urine, however, peculiar difficulties are met with owing to the fact that substances other than sugar in the urine (e. g., uric acid, pigments, kreatin, kreatinin, albumen, peptone, ammonium salts, as well as various drugs—chloral, salicylic acid, salol, phenacetin, antipyrin, acetanilid, salfonal, etc.) are capable of reducing the copper salts or of preventing the precipitation of cuprous oxid: thus Jolles[1] has shown that mistakes that correspond to as much as 0.24 per cent. of glucose may be made. The disturbing effect of other reducing substances in the urine can often be decreased by diluting the sample five or ten times (Zehuissen). More important still, glucose reduces at a temperature below 100 C.: the others usually only on boiling. Another method recommended by Focke[2] consists in boiling 10 grams with 5 g. copper-sulphate solution (1:9), to the well-cooled filtrate adding

William M. L. Fisk, M.D. Bellevue Hospital Medical College, New York City, 1863, a veteran of the Civil War, died from heart disease at his home in Brooklyn, N. Y., December 21, after an illness of four years, aged 63.

Henry C. McLean, M.D. New York University, New York City, 1873, a member of the New York State Medical Society, died at his home in Brooklyn, December 23, from neuritis, after an illness of a year, aged 44.

Merlin Caldwell, M.D. Western Pennsylvania Medical College, Pittsburg, 1904, of Ford City, Pa., died at Mercy Hospital. Pittsburg, December 23. after an illness of three weeks, from typhoid fever, aged 30.

Levi Mathiew, M.D. College of Physicians and Surgeons of Chicago. 1883, who recently moved to Chicago from St. Anne. Ill., died at his home from paralysis, December 11, after an illness of a year, aged 54.

Edward Hooker Dewey, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1862, died at his home in Meadville, Pa., December 21, from paralysis, after a long illness. aged 67.

Reuben Satterfield, M.D. University of Nashville, Tenn., 1900. was assaulted by a negro farm hand on his farm in Allen County, Ky.. November 24. and died December 1 from his injuries. aged 35.

Frederick C. Cluxton, M.D. University of the Victoria College. Coburg. Ont., 1871, committed suicide while mentally irresponsible. by shooting himself through the head, December 17. aged 58.

Elmore H. Wells, M.D. Bellevue Hospital Medical College, New York City, 1867. a surgeon in the federal service during the Civil War, died at his home in Meshoppen, Pa., December 13.

Enos Penwell, M.D. Indiana Medical College. La Porte, Ind., 1848. for more than half a century a practitioner of Shelbyville, Ill., died at his home in that city. December 24. aged 83.

Samuel Carson Garver, M.D. Medical Department University of Illinois. Chicago. 1898. committed suicide by taking carbolic acid at his office in Birmingham. Ala.. December 3. aged 32.

James W. Cairncross, M.D. Bellevue Hospital Medical College, New York City, 1875, died at his home in Wauwatosa. Wis., December 21. after a prolonged illness, aged 52.

Earl Devore, M.D. Medical College of Ohio. Cincinnati, 1900, died while en route from Florida to his home in Ripley, Ohio, December 28. from tubercular peritonitis, aged 26.

Jeremiah W. Dearborn, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor. 1857, died at his home in Maplewood. Maine, December 9, aged 72.

Thomas A. Curtis, M.D. College of Physicians and Surgeons in the City of New York. 1886. died from pneumonia at his home in Red Bank, N. J., December 23, aged 43.

Lewis A. Foote, M.D. University of Michigan Department of Medicine and Surgery. Ann Arbor, 1873, died at his home in Grand Rapids. Mich.. December 24. aged 56.

John S. Prettyman, M.D. New York, 1867, consul at Glasgow. Scotland, in Lincoln's administration, died at his home in Melford. Del., December 24, aged 79.

D. L. Stine, M.D. American Medical College, Indianapolis, 1897. a member of the State Dental Board. died from peritonitis following appendectomy. December 7.

John Alonzo Osborne, M.D. Medical Institute. Cleveland, 1855. died suddenly at his home in Portsmouth, Ohio. from heart disease. December 4. aged 73.

William Pike Phelon, M.D. Medical Department of the University at Keokuk, 1865. died at his home in San Francisco. December 29. from heart disease.

Joseph A. Ringe, M.D. University of Würzburg. Germany, 1868. died at his home in St. Louis. December 14. after an illness of seven months, aged 65.

Charles J. Miller, M.D. Hospital College of Medicine. Louisville. Ky.. 1901. died from pneumonia at his home in Shawnee, Okla.. December 25, aged 32.

James Orr, M.D. Tulane University of Louisiana Medical Department. New Orleans. 1871, died at his home in Terrell, Texas. December 25. aged 57.

William J. Jones, Jr., M.D. New York University. New York City. 1891. of Winston. N. C.. died suddenly near Verona. N. C., December 19. aged 34.

Lyman Leavit, M.D. Pennsylvania Medical College. Gettysburg, 1857, died at his home in Trenton, N. J., from pneumonia, December 29.

John E. Frick, M.D. University of Heidelberg, Germany, 1850, died at his home in Limaville, Ohio, Nov. 7, 1904, aged 80.

D. C. Wallace, M.D. Missouri Medical College, St. Louis, 1856, died at his home in Litchfield, Ill., December 21, aged 85.

Ellen O. Beebe, M.D. Illinois, 1879, was found dead in her apartments in Chicago, December 30, from exposure, aged 55.

George H. Miller, M.D. Rush Medical College, Chicago, 1874, died suddenly at his home in Galena, Ill., December 30.

Caleb N. Harrison, M.D. Johns Hopkins Medical School, Baltimore, died in Madison, Wis., Oct. 11, 1904.

Homer J. Doucet, M.D. Pennsylvania, 1863, died at his home in Philadelphia, December 20, aged 84.

Leonard D. Skilling, M.D. Illinois. 1878, died at his home in Kiowa, Kan., Nov. 1, 1904, aged 88.

Deaths Abroad.

P. Gradenigo, M.D., the well-known professor of ophthalmology at Padua, Italy. died there December 1, aged 73. He belonged to a family which gave four doges to the republic of Venice, and in his scientific career he has always been one of the pioneers. His pupils had collected his works into a *Festschrift*, which was to have been presented to him this month in honor of the thirtieth year of his professorship. His favorite field of work was surgical operations on the eyes, and he devised many new ones and perfected others, among them the technic which allows extraction of a cataract without the tedious waiting for it to ripen, and his plastic operations on the lids and on the cornea. He proclaimed the importance of massage for the eyes as early as 1882. and in 1894 published examples of its efficacy in treatment of detachment of the retina. He also invented several instruments and founded and edited the leading Italian ophthalmic journal.

A. Reder von Schelmann, M.D., former professor of surgery and later of dermatology at Vienna, died there November 10, aged 79. He had been president of the Vienna Doktoren-Collegium since 1891.

O. Bode, M.D., a well-known Berlin surgeon and writer on surgical subjects, succumbed to professional blood poisoning November 25, aged 44.

A. S. Herrero, M.D., professor of clinical medicine at Madrid. died there November 28.

K. Koester, M.D., professor of pathology at Bonn. died there December 2, aged 62.

Book Notices.

The Principles and Practice of Gynecology, for Students and Practitioners. By E. C. Dudley, A.M.. M.D.. President of the American Gynecological Society. Fourth Edition. Revised. With 409 Illustrations in Colors and Monochrome. of Which 18 Are Full-page Plates. Cloth. Pp. 771. Price. $5.00 net. Philadelphia and New York: Lea Brothers & Co. 1904.

One finds in this many changes from former editions. Much new matter has been added and much of the old has been thoroughly revised and rewritten. Of the greatest value are the four hundred illustrations. Most of these are new and they have been so well executed that they convey clearly the ideas intended. There can not be too many good illustrations, but poor ones are worse than none. The subdivision of the subject is a natural one and the subheads under the chapters have been conspicuously typed so that one may quickly turn to the particular point desired. The work is well arranged and published and, as the author's views are sound, it must take its place as one of the best text-books on the subject.

A System of Practical Surgery. By Prof. E. von Bergmann. M.D., P. von Bruns. M.D.. and J. von Mikulicz. M.D. Volume IV. Surgery of the Alimentary Tract. Volume V. Surgery of the Pelvis and Genitourinary Organs. Translated and Edited by William T. Bull. M.D.. Professor of Surgery. College of Physicians and Surgeons. Columbia University. New York. Edward Milton Foote. M.D., Instructor in Surgery, College of Physicians and Surgeons. Columbia University. New York. Carleton P. Flint. M.D.. and Walton Martin, M.D. Cloth. Pp. 758. Price. $30 per set. 5 volumes. New York and Philadelphia: Lea Brothers & Co. 1904.

Vols. I. II and III have already been reviewed in these columns. Vols. IV and V complete the work. The translation has been very liberal and at times the matter greatly condensed. The omission of the short bibliography which follows each principal subject in the original is a distinct loss to the translated edition, a loss for which the slight saving in space does not at all compensate. Each volume has its own index beside a general index at the end of the fifth volume which covers fifty pages and which is complete, enabling one quickly to find any subject desired.

A MANUAL AND ATLAS OF MEDICAL OPHTHALMOLOGY. By Sir Wm. R. Gowers, M.D., F.R.S. Fourth Edition. Edited by the Author and Marcus Gunn, M.B., F.R.C.S., Surgeon to the Royal London Ophthalmic Hospital. Pp. 318. Illustrated. Cloth. Price, $4.00. Philadelphia: P. Blakiston's Son & Co. 1904.

This well-known text-book, which has for so many years been a work of standard reference for the ophthalmologist, the neurologist and the practitioner of general medicine, is now reprinted, with additions, for the third time. The text has not undergone many alterations since the third edition was published, but the colored illustrations have been omitted. We must confess that we regard this innovation, in the reproduction of ophthalmoscopic pictures especially, as a decided improvement. The autotype plates, in making no pretense of reproducing the coloration of the fundi, are at least not misleading (as the colored plates were) and furnish a good idea of the changes in and the appearance of the ocular background. The original drawings are in sepia by the author and the collaboration of Mr. Marcus Gunn, the well-known ophthalmic surgeon, has further enriched the book. This valuable manual ought to be in the hands of every physician who desires to possess the great advantage of a knowledge of ophthalmoscopy as an indispensable help in the diagnosis of general disease.

A TEXT-BOOK OF HISTOLOGY. By Frederick R. Bailey, A.M., M.D., Adjunct Professor of Normal Histology, College of Physicians and Surgeons. Profusely Illustrated. Cloth. Pp. 481. Price, $3.00 net. New York: Wm. Wood & Co. 1904.

A casual examination of this volume leads to the impression that it is to a certain extent an abridgement of a very popular work on histology by another author. A careful and thorough review strengthens this impression and leads us to make the statement that the larger work has apparently suffered in being thus abridged. Furthermore, the author makes the mistake, as have many other writers, of giving a general technic not at all suitable for the tyro and altogether too elementary and incomplete for the teacher and research worker. It assumes preliminary knowledge on the part of the reader and yet is simply the technic which has proved useful in the hands of the author. The directions for technic, however, which are appended to each chapter are commendable because they are such as will be a benefit to all entering on the study of this subject. So, too, the short embryologic references at the beginnings of chapters serve a useful purpose. Far too much space is devoted to the discussion of so unimportant a tissue as fat, while, on the other hand, the description of bone leaves much to be wished for. The special chapters devoted to the skeletal system and to the muscular system are merely useless repetitions; nor is there any need for discussing the articulations in a text-book on histology. The illustrations, many of which are original, are excellent, as is also the mechanical work as a whole.

CLINICAL URINOLOGY. By Alfred C. Croftan, Professor of Medicine, Chicago Post-Graduate Medical College and Hospital: Illustrated. Cloth. Pp. 298. Price, $2.50 net. New York: Wm. Wood & Co. 1904.

The author states in his preface that this book was not intended to be a mere laboratory guide, nor a purely clinical treatise, but a description of the borderland between the laboratory and the clinic. This purpose, on the whole, has been accomplished satisfactorily. The book has many advantages. It is brief. It is written by a physician who has had much more training in chemical examinations than practitioners on the average receive. The author has taken especial pains to interpret urinary findings clinically, so far as it is possible to do so at present, and this last is the feature of the book which will make it most attractive, we think, to the practitioner. The chapters dealing with albuminuria, the purin bases, glycosuria, acetonuria, the conjugate sulphates and glycuronates are modern and interesting. The inorganic constituents of the urine receive an unusual degree of attention, but deservedly so in the light of newer investigations which have revealed to us an importance of these substances hitherto unsuspected. A welcome chapter is that on the determination of the renal function in which are discussed the value of cryoscopy, the methylene-blue test, the phlorizin method and the toxicity of the urine as an index of renal activity. Here and there in this volume the dogmatic tone adopted jars a little, but dogmatism can be more easily condoned in a book of this kind than a wavering indecision. Now and then the choice of method might have been improved, we think; the convenient Hopkins method (as now modified) for estimating uric acid might well have taken the place of the unreliable Heintz method; Penzoldt's test for acetone with orthonitrobenzaldehyd is too good to be omitted; the reaction for indican with dimethylamidobenzaldehyd is perhaps the most delicate test we have for that body and should be included in another edition, along with, perhaps, fuller details rather than bare mention of the rather rough but clinically helpful methods of quantitative estimation of indican worked out by H. Straus and J. Bouma. The reliability of the fermentation test for glucose is scarcely sufficiently emphasized, while on the other hand the ease of differentiating the various crystalline ozazones by melting point determinations is exaggerated. The word "serin" used on page 10 as synonymous with serum albumin should no longer be employed in this way, since by "serin" chemists now understand a definite chemical compound, namely, alpha-amino-beta-oxypropionic acid. The "sodium nitrate" recommended in Arnold's test on page 107 appears to be a misprint for sodium nitrite. The book should have a distinct influence in stimulating interest in the newer studies of the urine and in making clear to the clinician the significance of the results which the chemical methods, especially of urinary examinations, are capable of yielding.

THE BOOKS OF A YEAR.

List of Books Published on Medical Subjects During the Year 1904.

The following is a list of the new books published in the United States in the year 1904. It may contain some books that were published before 1904, as we have had to depend on the replies of publishers to our letters and they may not have fully understood in every case the limits we desired to put on the list. Some books may have been omitted which should be here, but we have tried to make the list complete. Second editions or other republications are not included, nor are foreign books which are not issued under the imprint of an American publishing house.

Anatomy.

Anatomy of the Brain. J. F. Burkholder. Price, 2.00. Engelhard.

Laboratory Manual of Human Anatomy. Lewellys F. Barker. $5.00. Lippincott.

Treatise on Applied Anatomy. Edward H. Taylor. $9.00. Lippincott.

Bacteriology.

Bacteriology and the Public Health. George Newman. $5.00. Blakiston.

Clinical Diagnostic Bacteriology, Including Serum Diagnosis and Cytodiagnosis. Alfred C. Coles. $2.75. Blakiston.

Rabies, Its Place Among Germ Diseases and Its Origin in the Animal Kingdom. David Sime. 10½ shillings. Macmillan.

Chemistry.

Clinical Urinology. Alfred C. Croftan. $2.50. Wood.

Elements of Chemistry. M. M. Pattison Muir. $3.50. Blakiston.

Epitome of Inorganic Chemistry and Physics. A. McGlannan. $1.00. Lea.

Epitome of Organic and Physiological Chemistry. A. McGlannan. $1.00. Lea.

Examination of the Urine. G. A. de Santos Saxe. $1.50. W. B. Saunders.

Immune Sera. Hemolysins, Cytotoxins and Precipitins. A. Wassermann. $1.00. Wiley.

Manual of Clinical Microscopy and Chemistry. Herman Lenhartz. $3.00. Davis.

Outlines of Physiological Chemistry. S. P. Beebe and B. H. Buxton. $1.50. Macmillan.

Practical Physiological Chemistry. J. A. Milroy and T. H. Milroy. $1.60. Longmans.

Text-book of Quantitative Chemical Analysis by Gravimetric, Electrolytic, Volumetric and Gasometric Methods. J. C. Olsen. $4.00. Van Nostrand.

Toxicology. Edwin Welles Dwight. $1.00. Lea.

Uric Acid, an Epitome of the Subject. Alexander Haig. $1.00. Blakiston.

Diagnosis.

Manual of Serum Diagnosis. O. Rostoski. $1.00. Wiley.

Medical Laboratory Methods and Tests. Herbert French. $1.50. Keener.

Serums, Vaccines and Toxins in Treatment and Diagnosis. Wm. Cecil Bosanquet. $2.00. Keener.

Surgical Diagnosis. James Berry. $2.00. Blakiston.

Text-book of Clinical Diagnosis. L. Napoleon Boston. $4.00. Saunders.

Genitourinary, Cutaneous and Venereal Diseases.

Development and Anatomy of the Prostate Gland. W. G. Richardson. $3.75. Churchill.

Prostatic Hypertrophy. By C. M. Phillips and 40 Authors. $1.75. Mathews.

Social Diseases and Marriage. *Social Prophylaxis. Prince A.* Morrow. $3.00. Lea.

Syphilis and Gonorrhea. C. F. Marshall. $2.25. Redman.

Value of Ureteric Meatoscopy in Obscure Diseases of the Kidney. E. Hurry Fenwick. $2.50. Keener.

Histology.

Normal Histology. Jeremiah S. Ferguson. $5.00 Appleton.

Text book of Histology. Frederick R. Bailey. $3.00. Wood.

Hygiene.

Beauty Through Hygiene. Emma E. Walker. $1.00. Barnes.

Examination of Water and Water Supplies. John C. Thresh. $4.00. Blakiston.

Food Inspection and Analysis. Albert E. Leach. $7.50. Wiley.

Health and Disease in Relation to Marriage and the Marriage State. Vol. I. $7.00. Redman.

Health, *Strength and Power.* Dudley A. Sargent. $1.75. Caldwell.

Methods of Teaching Gymnastics. W. G. Anderson. $1.25. Hinds and Noble.

Physical Education by Muscular Exercise. Luther H. Gulick. *75 cents. Blakiston.*

The Prevention of Disease. $7.50. Funk & Wagnalls.

Suppression of Tuberculosis. E. von Behring. $1.00. Wiley.

Weather Influences Edwin Grant Dexter. $2.00. Macmillan.

Laryngology.

Adenoids. Wyatt Wingrave. $1.00. Keener.

Cleft Palate and Harelip. Edmund Owen. $1.00. Keener.

Materia Medica, Pharmacology and Therapeutics.

Action of Light as a Therapeutic Agent. Leonard K. Hirshberg. Snow & Farnham.

Diet in Health and Disease. Julius Friedenwald and John Ruhräh. Saunders.

Elements of General Radiotherapy for Practitioners. Leopold Freund. $5.00. Rebman.

Introduction to Pharmacognosy. Smith Ely Jelliffe. $2.50. Saunders.

Light Energy; Its Physics, Physiological Action and Therapeutic *Applications. Margaret A. Cleaves. $5.00.* Rebman.

Modern Practical Electricity. R. M. Walmsley. $12.00. Keener.

Philosophy of Therapeutics. Eldridge C. Price. $2.00. Nunn & Co.

Practical Dietetics. Diet in Health and Disease. A. L. Benedict. $1.50. Engelhard.

Radiotherapy, Phototherapy and High Frequency Currents. Charles Warren Allen. $4.50. Lea.

Roentgen Ray Diagnosis and Therapy. Carl Beck. $4.00. Appleton.

Self-cure of Consumption Without Medicine, with a Chapter on the Prevention of Consumption and Other Diseases. Charles H. Stanley Davis. Treat.

Text-book of Alkaloidal Therapeutics. W. F. Waugh and W. C. Abbott. $5.00. Clinic.

Text-book of Materia Medica. Robert A. Hatcher and Torald Sollman. $2.00. Saunders.

Therapeutics of Mineral Springs and Climates. I. Burney Yeo. $3.50. Keener.

Unconscious Therapeutics, or the Personality of the Physician. Alfred T. Schofield. $3.50. Blakiston.

Miscellaneous.

All Around Specialist. J. R. McOscar. $3.50. Keener.

Dictionary of New Medical Terms. George M. Gould. $5.00. Blakiston.

Appleton's Medical Dictionary. Edited by Frank P. Foster. *$10.00. Appleton.*

Doctor's Confession. Wm. Hinshaw. $1.25. Mathews.

Physician Versus Bacteriologist. O. Rosenbach. $1.50. Funk & Wagnalls.

Railway and Other Accidents. Allan M. Hamilton. $3.50. Wood.

Sexual Life. C. W. Malchow. $3.00. The Burton Co., Minneapolis.

Text book of Legal Medicine and Toxicology. Edited by Frederick Peterson and Walter S. Haines. $5.00. Saunders.

Nervous and Mental Diseases.

Epilepsy and Its Treatment. William P. Spratling. $4.00. Saunders.

Epitome of Nervous and Mental Diseases. Joseph Darwin Nagel. $1.00. Lea.

Force of Mind. A. T. Schofield. $2.00. Funk & Wagnalls.

Insanity in Everyday Practice. E. G. Younger. $1.00. Keener.

Lectures on Clinical Psychiatry. Dr. Emil Kraepelin. $3.50. Wood.

Mental Defectives: Their History, Treatment and Training. Martin W. Barr. $4.00. Blakiston.

Multiple Personality, an Experimental Investigation Into the Nature of Human Individuality. Boris Sidis and Simon P. Goodhart. $2.50. Appleton.

Nerves in Disorder. A. T. Schofield. $1.50. Funk & Wagnalls.

Outlines of *Psychiatry.* Charles Gilbert Chaddock. $2.50. Mathews.

Practical Treatise on Nervous Diseases. F. Savary Pearce. $6.00. Appleton.

Subjective Sensations of Sight and Sound. Abiotrophy and Other Lectures. William R. Gowers. $2.00. Blakiston.

Text-book of Insanity Based on Clinical Observations. R. von Krafft-Ebing. $4.00. Davis.

"The Blues," Causes and Cure. A Variety of Nerve Exhaustion so Largely Prevalent in Our Modern Life. Albert Abrams. $1.50. Treat.

Treatise on Diseases of the Nervous System. L. Harrison Mettler. $5.00. Cleveland Press, Chicago.

Obstetrics and Gynecology.

Atlas and Epitome of Operative Gynecology. O. Schaffer, edited with additions by J. Clarence Webster. $3.00. Saunders.

Mothers' Manual. Evelyn Lincoln Coolidge. $1.00. Barnes.

Obstetrics for Nurses. Joseph B. De Lee. $2.50. Saunders.

Physician's *Practical Gynecology.* W. O. *Henry, Omaha.* The Review Press, Lincoln, Neb.

Manual of Practical Ophthalmology. George A. Berron. Lippincott.

Ophthalmology.

Biographic Clinics. Vol. II. George M. Gould. $1.00. Blakiston.

Commoner Diseases of the Eye, How to Detect and How to Treat Them. Casey A. Wood and Thomas A. Woodruff. $1.75. Engelhard.

Diseases of the Eye. L. Webster Fox. $4.00. Appleton.

Hand-book of the Anatomy and Diseases of the Eye and Ear. D. B. St. John Roosa and A. Edward Davis. $1.00. Davis.

Manual of Practical Ophthalmology. George A. Berry, Lippincott.

Modern Ophthalmology. James Moores Ball. $7.00. Davis.

Ophthalmic Year-book. Edward Jackson. Herrick Book and Stationery Co., Denver.

Optical Dictionary. Edited by Charles Hyatt-Woolf. $1.00. Blakiston.

Pathology of the Eye. J. Herbert Parsons. Vol. I. Histology—*Part 1. $3.50. G. P. Putnam.*

Principles of Refraction in the Human Eye Based on the Laws of Conjugate. Foci. Swan M. Burnett. $1.00. The Keystone, Philadelphia.

Strabismus or Squint. Francis Valk. $1.75. Putnam.

Pathology.

Atlas and Epitome of General Pathologic Histology. H. Dürck. $5.00. Saunders.

Friedberger and Frohner's Veterinary Pathology. Translated and edited by M. H. Hayes. $4.00. Keener.

Manual of Antenatal Pathology and Hygiene. The Embryo. J. W. *Ballintyne.* Wm. Green & Sons, Edinburgh.

Manual of Pathology. Sidney H. C. Martin. $4.00. Blakiston.

Text-book of Pathology. Joseph McFarland. $5.00 net. Saunders.

Pediatrics.

Adolescence. Vols. I and II. G. Stanley Hall. $7.50. Appleton.

Epitome of Pediatrics. Henry E. Tuley. $1.00. Lea.

Lectures on Diseases of Children. R. Hutchinson. $2.40. Longman.

Nutrition of the Infant. Ralph Vincent. $3.50. Wood.

Squint Occurring in Children. E. A. Browne and Edgar Stevenson. $1.00. Keener.

Summer Diarrhea of Infants. H. Illoway. $1.00. E. R. Pelton, New York.

Physiology and Embryology.

Blood Pressure as Affecting Heart, Brain, Kidneys and General Circulation. Louis Faugeres Bishop. $1.00. Treat.

Clinical Study of the Blood Pressure. Theo. C. Janeway. $3.00. Appleton.

Introduction to Vertebrate Embryology. Albert Moore Reese. $1.40. Putnam.

Lymphatics, General Anatomy of the Lymphatics. G. Delamere and P. Poirier. $5.00. Keener.

Manual of Experimental Physiology. Winfield S. Hall. $2.75. Lea.

Physiologic Economy in Nutrition. Russell H. Chittenden. Frederick A. Stokes Co., New York.

Physiology and Pathology of the Urine, with Methods for Its Examination. J. Dixon Mann. $3.00. Lippincott.

Recent *Development of Physical* Science. William C. D. Whetham. $2.00. Blakiston.

Text-book of Human Physiology. Albert P. Brubaker. $4.00 Blakiston.

Text-book of Physiology. Isaac Ott. $3.00. Davis.

Practice of Medicine.

Arrhythmia of the Heart. K. F. Wenkenbach. $4.50. Keener.

Beri-beri; Its Symptoms and Symptomatic Treatment. Percy Netterville Gerrad. $1.00. Blakiston.

Clinical Cases of Cancer of the Breast. Cecil H. Leaf. 80 cents. Keener.

Clinical Lectures and Essays on Abdominal and Other Subjects. H. D. Rolleston. $1.50. Blakiston.

Diseases of the Intestines and Peritoneum. Herman Nothnagel. $5.00. Saunders.

Diseases of the *Liver, Gall Bladder and* Bile Ducts. H. D. Rolleston. $6.00. Saunders.

Disorders of Metabolism and Nutrition. Carl von Noorden. Part V—Saline Therapy. 75 cents. Treat.

Graves' Disease With and Without Exophthalmic Goiter. William Hanna Thompson. $1.50. Wood.

Laboratory Studies in Tropical Medicine. C. W. Daniels. $4.00. Blakiston.

Lectures Chiefly Clinical and Practical on Diseases of the Lungs and Heart. James A. Lindsay. $3.50. Wood.

Lectures to General Practitioners on Diseases of the Stomach and Intestines. Boardman Reed. $5.00. Treat.

New Methods of Treatment. J. Laumonier. $2.50. Keener.

Practical Guide to the Administration of Nauheim Treatment in Chronic Diseases of the Heart. L. Thorne. $1.00. Keener.

Principles of Relief. Edward T. Devine. Macmillan.

Short Treatise on Anti-typhoid Inoculation. A. Wright. $1.25. Keener.

System of Clinical Medicine. Thomas D. Savill. Vol. I and II. $4.50. Keener.

Treatment of Some Acute Visceral Inflammations. David B. Lees. $1.50. Blakiston.

Tuberculosis and Acute General Miliary Tuberculosis. G. Cornet. $5.00. Saunders.

Surgery.

Aseptic and Antiseptic Preparations and Treatment of Emergencies After Abdominal Surgical Operations. G. Wackerhagen. $1.00. E. R. Pelton, 19 E. 16th St., New York.

Case Teaching in Surgery. Herbert L. Burrell and John Bapst Blake. 75 cents. Blakiston.

Closure of Laparotomy Wounds as Practiced in Germany and Austria. Edited and translated by Walter H. Swaffield. Blakiston.

"First Aid" Hand Book. M. J. Shields, Carbondale, Pa. Published by the Office of Thomas Boundy, Jermyn, Pa.

Gallstones and Their Surgical Treatment. B. G. A. Moynihan. $4.00. Saunders.

Hand Book of Surgery. Frederick R. Griffith. $2.00. Saunders.

Handbook of Surgical Anatomy. G. A. Wright and C. H. Preston. $1.50. Blakiston.

Manual of Fever Nursing. Reynold Webb Wilcox. $1.00. Blakiston.

Manual of Intragastric Technique. George Herschell. $2.50. Keener.

Regional Minor Surgery. George Gray Van Schaick. $1.50. International Journal of Surgery Co., 100 William St., New York.

Surgery. A Manual for Students and Practitioners. M. D'Arcy Magee and Wallace Johnson. $1.00. Lea.

Surgery of the Diseases of the Appendix Vermiformis and Their Complications. W. H. Battle and E. M. Corner. $2.50. Keener.

Surgery of the Heart and Lungs. Benjamin Merrill Ricketts. $5.00. The Grafton Press, New York.

Surgical Anatomy of the Head and Neck. John B. Deaver. $12.00. Blakiston.

Surgical Emergencies. The Surgery of the Abdomen. Part 1. Bayard Holmes. $2.00. Appleton.

Surgical Treatment of Bright's Disease. George M. Edebohls. $2.00. Frank F. Lisiecki, New York.

State Boards of Registration.

COMING EXAMINATIONS.

Wisconsin Board of Medical Examiners, Hotel Pfister, Milwaukee, January 9-11. Secretary, Filip A. Forsbeck, M.D., Milwaukee.

State Medical Board of the Arkansas Medical Society, Little Rock, January 10. Secretary, J. R. Runyan, M.D., Little Rock.

Indiana State Board of Medical Registration and Examination, State House, Indianapolis, January 10-12. Secretary, W. T. Gott, M.D., Crawfordsville.

Vermont State Board of Medical Censors, Y. M. C. A. Building, Burlington, January 11-12. Secretary, S. W. Hammond, M.D., Rutland.

Board of Medical Supervisors of the District of Columbia, Washington, January 12. Secretary, Wm. C. Woodward, M.D., Washington, D. C.

Illinois State Board of Health, The Great Northern Hotel, Chicago, January 19-21. Secretary, J. A. Egan, M.D., Springfield.

New York—Three Medical Boards, New York, Albany, Syracuse and Buffalo, January 24-27. H. J. Hamilton, Education Department, Albany.

New Hampshire State Boards, University Club, Concord, February 1-2. Regent, Henry C. Morrison, Concord.

Kansas State Board of Medical Registration and Examination, Topeka, February 14-15. Secretary, G. F. Johnston, M.D., Lakin.

New Mexico Medical Board Can Not Examine.—Solicitor General G. W. Pritchard has given it as his opinion that the present medical-practice law in New Mexico does not authorize examinations. Therefore, an applicant who can not present satisfactory evidence that he is a graduate of a medical college in good standing can not be licensed. The opinion further upholds the right of the board to exercise discretion as to what colleges are "in good standing," taking into consideration clinical opportunities, etc.

Utah October Report.—Dr. R. W. Fisher, secretary of the Utah State Board of Medical Examiners, reports the written examination held at Salt Lake City, October, 1904. The number of subjects examined in was 20; total questions asked, 120; percentage required to pass, 75. The total number examined was 12, of whom 8 passed and 4 failed. The following colleges were represented:

College.	Year Grad.	Per Cent.
PASSED.		
Chicago Homeo. Med. Coll	(1879)	85.8
Univ. of Colorado Med. Dept	(1904)	83.3
College of P. and S., Baltimore	(1904)	80.3
St. Louis Univ., Med. Dept	(1904)	76.7
Rush Medical College	(1900)	87.3
Univ. of Toronto, Canada	(1893)	88.7
Denver and Gross Med. Coll	(1903)	78.5
Tufts Med. Coll., Boston	(1904)	86.5
FAILED.		
American Med. Coll., St. Louis......(1885 67.3*,	(1898)	72.6
Coll. of Med. and Surg., Chicago	(1903)	72.6
Rush Medical College	(1903)	74

*Second examination.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, week ending Dec. 31, 1904:

Smart, Robert, asst.-surgeon, leave of absence extended fourteen days.

Hall, John D., asst.-surgeon general, relieved from duty in Philippine Division and ordered to proceed to San Francisco and report on arrival to the military secretary for further orders.

Jones, Percy L., asst.-surgeon, relieved from duty on transport *Sumner* and ordered to report at Medical Supply Depot, New York City for temporary duty, to examine medical supplies now being delivered at that depot.

Buck, Carroll D., asst.-surgeon, granted ten days' leave of absence on being relieved from duty with First Battalion Philippine Scouts, World's Fair Grounds, St. Louis, and Dec. 24, 1904, assignment to duty at Fort Des Moines, Iowa, changed to Fort Leavenworth, Kan.

Shook, Jay R., asst.-surgeon, relieved from duty at Fort Leavenworth, Kan., and ordered to Fort Des Moines, Iowa.

Brown, Henry D., contract surgeon, returned to Fort Worden, Wash., December 19, from leave of absence.

Freeman, Charles E., contract surgeon, assigned to temporary duty at the Depot of Recruits and Casuals, Fort McDowell, Angel Island, Cal.

Kellogg, Preston S., contract surgeon, returned to duty at Fort Robinson, Neb., December 18, from leave of absence.

Bell, Leonard P., and Hansen, Morris J., contract surgeons, returned to duty at San Francisco December 19 from leave of absence, and will sail for the Philippines December 31.

Lemmon, Robert, contract surgeon, ordered from Fort DuPont, Del., to Fort Terry, New York, for temporary duty, and on its completion, to his proper station, Fort McKinley, Me.

McMillan, Clemens W., contract surgeon, granted leave of absence for fifteen days about Jan. 10, 1905.

Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending Dec. 31, 1904:

Grunwell, A. G., surgeon, detached from the *Dixie* and ordered to the Naval Hospital, New York, for treatment.

Ledbetter, R. E., P. A. surgeon, detached from the *Lancaster* and ordered to the *Dixie*.

Kennedy, J. T., P. A. surgeon ordered to the Naval Station, Guantanamo, Cuba, and to additional duty on the *Amphitrite*.

Page, J. E., P. A. surgeon, ordered to the *Lancaster*.

Means, V. C. B., surgeon, ordered to the Naval Hospital, Philadelphia.

Bell, W. L., P. A. surgeon, when discharged from treatment at the Naval Hospital, New York, ordered home and granted sick leave for three months.

Janney, W. H., A. A. surgeon, detached from the *Marcellus* and ordered to the *Cæsar*.

Grove, W. B., surgeon, detached from the *Atlanta* and ordered home to wait orders.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending Dec. 28, 1904:

Smith, A. C., surgeon, detailed as inspector of unserviceable property at Camp Hutton, La.

Rosenau, M. J., P. A. surgeon, detailed to represent the Service at the Second Annual Mosquito Exterminating Convention, New York, Dec. 16-17, 1904. Detailed to represent the Service at the annual meeting of the Society of American Bacteriologists at Philadelphia, Dec. 27-28, 1904.

Von Ezdorf, R. H., P. A. surgeon, to report in person to Rear Admiral Walker, U. S. N., for duty in connection with quarantine in the Isthmian Canal Zone, Republic of Panama.

McClintic, T. B., P. A. surgeon, granted leave of absence for five days from Dec. 27, 1904, under Paragraph 191 of the Regulations.

Korn, W. A., P. A. surgeon, granted leave of absence for seven days.

Berry, T. D., asst.-surgeon, to proceed to Perth Amboy, N. J., and assume temporary charge of Service during absence on leave of P. A. Surgeon W. A. Korn.

Salmon, T. W., asst.-surgeon, to report at the Bureau, Washington, D. C., for special temporary duty.

BOARD CONVENED.

Board convened to meet at the Hygienic Laboratory, Washington, D. C., on call of the chairman, for the examination and marking of applications for appointment as technical assistants in zoology, chemistry and pharmacology. Detail for the board: P. A. Surgeon M. J. Rosenau, Director of Hygienic Laboratory, chairman; Ch. Wardell Stiles, Chief of Division of Zoology; Reid Hunt, Chief of Division of Pharmacology, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended Dec. 30, 1904:

SMALLPOX—UNITED STATES.

Florida: Jacksonville, Dec. 17-24, 1 case.

Illinois: Chicago, Dec. 17-24, 20 cases, 1 death; Springfield, Nov. 28-Dec. 21, 5 cases.

Kentucky: Louisville, Dec. 15-22, 1 case.

Louisiana: New Orleans, Dec. 18-24, 7 cases, 4 imported.

Michigan: At 70 localities, Dec. 10-17, present.

Minnesota: Meeker Co., Dec. 21-19, 1 case; Dec. 12-19, Otter Tail Co., 1 case; Rice Co., 12 cases; Wilkin Co., 1 case.

New Jersey: Camden, Dec. 18-24, 1 case.

New York: New York City, Dec. 18-24, 1 case.

Ohio: Cincinnati, Dec. 16-23, 2 cases.

Pennsylvania: Dec. 17-24, Johnstown, 1 case; Philadelphia, 1 case.

South Carolina: Charleston, Dec. 10-17, 2 cases.

Tennessee: Nashville, Dec. 17-24, 4 cases.

Washington: Nov. 1-30, Pierce Co. (including Tacoma), 2 cases; Walla Walla Co., 5 cases; Seattle, 1 case.

Wisconsin: Milwaukee, Dec. 10 24, 40 cases.

SMALLPOX—FOREIGN.

Argentina: Bahia Blanca, Nov. 18, present; Buenos Ayres, Sept. 1-30, 22 deaths.

Austria: Prague, Nov. 26-Dec. 3, 18 cases.

Brazil: Bahia, Nov. 12-26, 28 deaths; Rio de Janeiro, Nov. 6-27, 373 cases, 160 deaths.

Ecuador: Guayaquil, Nov. 30-Dec. 7, 3 deaths.

France: Lyon, Nov. 20-Dec. 3, 1 case; Paris, Dec. 3-10, 9 cases.

Great Britain: Glasgow, Dec. 8-16, 2 cases; London, Nov. 26-Dec. 10, 3 cases; Dec. 3-10, Newcastle-on-Tyne, 21 cases; Nottingham, 3 cases; South Shields, 2 cases.

India: Bombay Nov. 22-29, 5 deaths; Calcutta, Nov. 19-26, 2 cases.

Italy: Palermo, Nov. 26-Dec. 10, 33 cases, 15 deaths.

Russia: Odessa, Nov. 26-Dec. 3, 1 case.

Turkey: Constantinople, Nov. 27-Dec. 4, 15 deaths.

YELLOW FEVER.

Ecuador: Guayaquil, Nov. 25-Dec. 7, 3 deaths, 1 case on S. S. *Limari* at Puna from Panama.

Mexico: Coatzacoalcos, Dec. 10-17, 2 cases; Juchitan, Dec. 11-17, 1 case.

Panama: Panama, Dec. 12-19, 3 cases.

Medical Organization.

ORGANIZATION WORK NEEDED IN KANSAS.

J. N. McCormack, M.D.

CHAIRMAN OF THE COMMITTEE ON ORGANIZATION.
BOWLING GREEN, KY.

Although a majority of the physicians met by me in Kansas compare favorably with their brethren in the older states, and in spite of the fact that 800 of the 2,600 physicians are enrolled as members of the state society, outside of Wichita, where an excellent city society has existed for two years, the profession is practically unorganized in every section visited by me.

There are the usual local dissensions in most sections, but the condition most noticeable and most impressive to a stranger is the almost universal and absolute indifference to every professional interest which is not strictly and immediately personal. As would be expected from the foregoing statements, all the evils of commercialism are pronounced in such sections, including rate-cutting, commissions by surgeons, and the various questionable methods of securing practice, associated, as these evils always are in my experience, with a lack of financial prosperity in the rank and file of the profession, in striking contrast to the commercial wealth of the country. In some rich towns and counties one could not but be impressed with the idea that the country is developing more rapidly than the profession, and that systematic postgraduate work and a general awakening are necessary for the good of both the profession and the public.

District societies, overlapping each other in every direction, and supported by a few of the best men, had formerly assumed proportions not found elsewhere, all of them doing really excellent work, but none of them reaching, interesting nor benefiting the mass of the profession. Until two years ago some of these were as large as the state society—which, before that time, was practically confined to the northeastern section of the state—and were organized and run in a spirit of more or less distinct rivalry and antagonism to that body. Add to this the fact that there has been no co-operation between the State Board of Medical Examiners and the State Board of Health and the State Medical Society, that the officers and members of these boards, who should be selected, or at least nominated to the appointing power, by the organized profession, as its executive agents, seldom even attend the meetings of the society, and that the officers of the latter body have heretofore done little more than to issue a program for, and to perform the routine duties incident to, the annual meeting, with no real county societies anywhere, and there will be little difficulty in accounting for existing conditions.

What is needed in Kansas is zealous, personal, self-sacrificing labor, not only on the part of the councilors and of the other officials of the state society, but of all who can be induced to assist them from Topeka, Wichita, Kansas City, Hutchison and elsewhere, until a real, live society exists in every county containing five or six physicians, to make a practical study of and to promote the interests of every member and citizen of the jurisdiction.

First, the president and secretary of the state society need to wake up to the importance of their positions, as similar officers have done in other states, and to assist and to encourage the councilors in the onerous and difficult duties so that they may be able to complete the tasks set for them before the next meeting. The state journal is doing excellent work, and Dr. Furst has accomplished much in his district, but most of the other councilors have done practically nothing. I found that they had expected to organize county societies by a desultory correspondence and were despondent because they had had less tangible results than children usually do who send letters up the chimney to Santa Claus before Christmas. Such an organization as is demanded by the best interests of the profession and of humanity involves intelligent thought, labor and expense on the part of those charged with the duty. My meetings were well attended considering the short and imperfect notice it was possible to give, and the interest and enthusiasm manifested everywhere indicated that the profession was ripe for a real reform, if those chosen to lead the movement can be induced to put some spirit into their work and push into effect the comprehensive methods which have proven so effective elsewhere.

The great natural wealth of Kansas, and the rapid encroachment being made on the arid sections by cultivation and tree growth, must make it one of the foremost states in the union. Although often there before, this was impressed on me more forcibly during this trip, traveling chiefly in the daytime, and often riding for hundreds of miles over fertile plains stretching out to the sky-line as rich as the famous Blue Grass regions. With proper organization, possible only through such a system of local societies as will bring the physicians of each community into fellowship and co-operation for their own and the public good, the future of the medical profession is as promising as that of the country.

IN MISSOURI.

My western trip ended with a meeting at Kansas City in the evening of December 2. Although a meeting called on short notice, with limited information as to its purpose, the attendance, and more especially the active and appreciative spirit with which the work was taken up, admirably indicated the influence which a good society, holding weekly meetings, will exert in any community. In the frank discussion which followed my talk it was shown that, while there is much to be done in that city even locally, so much has already been done, and the personal relations and enthusiasm in the large, active working force are such that anything is possible of accomplishment by a more extensive and searching utilization of the forces at the command of the profession. Both the city and state are overrun with quackery to an unusual degree, and my information is that professional conditions are bad in many counties in Missouri, but if St. Louis and St. Joseph will join hands with Kansas City and with the officers and councilors of the state association in earnest work, the foundation can be laid for remedying all of these evils before the next annual meeting.

Society Proceedings.

WESTERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

Fourteenth Annual Meeting, held in Milwaukee, Wis., Dec. 28-29, 1904.

The President, Dr. Charles H. Mayo, Rochester, Minn., in the Chair.

Officers Elected.

President, Dr. H. D. Niles, Salt Lake City, Utah; vice-presidents, Drs. E. Wyllys Andrews, Chicago, and W. W. Grant, Denver; secretary-treasurer, Dr. B. B. Davis, Omaha.

Kansas City, Mo., was selected as the place of meeting in 1905, with Dr. H. C. Crowell as chairman of the committee of arrangements.

Stone in the Kidney.

DR. A. L. WRIGHT, Carroll, Iowa, drew the following conclusions:

1. Kidney stone may occur at any time of life, from the earliest to ripe old age. 2. These stones are the most frequent, and give rise to the greatest amount of suffering of any form of surgical disease of the kidney. The clinical manifestations of kidney stone do not depend on its size. A small stone, just large enough to prevent its escape, and composed of oxalate of lime, will cause more suffering and damage to the kidney parenchyma than a very much larger deposit of softer formation, as well as completely disable the patient while the destructive changes are taking place, although the clinical symptoms are not intensely active. 3. While generally unilateral, stone occasionally occurs in both kidneys, or the reflex symptoms may point most prominently to the sound kidney, the stone being found not infrequently on the side free from pain. 4. Diagnosis is not difficult in the typical cases, but the stone remaining quiescent in some for an indefinite period makes recognition almost impossible. 5. Owing to the fact that kidney stone may put on the livery of infectious diseases, the diagnosis is difficult, if not impossible, in those cases where the classical symptoms are absent. 6. There are few diseases of the kidney more certainly fatal, when left to themselves, and more successfully treated when encountered by proper surgical interference, arresting the destructive changes taking place in the kidney, and restoring the viscus to its physiological functions.

DISCUSSION.

DR. ALEX. HUGH FERGUSON, Chicago, said that pain is sometimes very deceptive. It is both local and referred: local in the region of the kidney itself, and referred to different parts of the body, chiefly along the genito-urinary tract toward the testicle; sometimes toward the midline of the abdomen; at other times toward the ensiform cartilage in the region of the gall bladder and duodenum, and not infrequently it is referred to the back. Pain is caused in nearly all cases at first, when there is no septic urine, by stretching of the pelvis of the kidney and of the kidney tissue, the calices, etc. A quiescent stone does not always cause colic, although it frequently gives rise to referred pain. In the diagnosis one should consider tumor of the kidney, recurrent attacks of interstitial nephritis, and tuberculosis of the kidney. The *x*-ray is one of the best diagnostic aids. Dr. Ferguson called attention to the dangers incident to the passage of such instruments as the segregator, cystoscope, etc.

DR. W. D. HAINES said he had made over two thousand autopsies, and in about 50 per cent. of the cases he found stones of variable sizes in the kidney. In those few cases in which the history could be traced, it was surprising to find how infrequently symptoms referable to the kidney were complained of. In treating these cases surgically, one of the principal things to determine is the presence of a kidney on the opposite side.

DR. WRIGHT maintained that the pain is inflammatory in character, and is not due to stretching of the kidney tissue. Many kidneys are opened, where the clinical manifestations indicate the existence of stone, but none is found, except possibly a little debris. Furthermore, where the deposit consists of oxalate of lime, the pain is very excruciating. The stone is too large to engage in the ureter, but not large enough, however, to stretch the pelvis or parenchyma of the kidney, or to produce any stretching effect whatever. He believes the same is true of kidney stone as of gallstone, the pain not being due to the passage of the stone, but to an inflammatory reaction. When such kidneys are opened and drained, relief is prompt, even when no stone or stones are found.

Newer Aids to Diagnosis in Diseases of the Urinary Tract.

DR. M. L. HARRIS, Chicago, arranged the newer aids to diagnosis in diseases of the urinary tract in the following order, according to their value: (1) The cystoscope. (2) Ureteral catheterization or segregation, with comparative analyses of the separate urines. (3) The *x*-ray. (4) The phloridzin test. (5) Comparative cryoscopy of the separate urines. (6) Cryoscopy of the blood, with the necessary corrections made.

DISCUSSION.

DR. B. B. DAVIS asked whether the essayist had observed temporary anuria in any of the cases, enough to interfere materially with the value of the test. Dr. Davis related a case in which temporary anuria followed the use of the segregator.

DR. HARRIS said he had observed temporary anuria in a number of instances, lasting sometimes a few minutes, sometimes ten or fifteen minutes, and sometimes as long as thirty or forty minutes, but how long it would have lasted had the examination been continued he does not know. Temporary anuria, however, is exceptional. He has also seen temporary anuria follow the introduction of the ureteral catheter, lasting for several hours, or until the catheter was withdrawn.

Methods of Exploring the Abdomen, and a New One.

DR. ALEX. HUGH FERGUSON, Chicago, stated that in the daily round of work the surgeon meets cases requiring colpotomy, anterior or posterior, to remove myomata, or cysts, and that these cases often give a history of stomach, gallbladder, kidney or bowel disturbances. An examination of the abdominal organs is highly satisfactory, although oftentimes one hardly feels justified in opening through the abdominal wall for that purpose. The problem is solved by passing the hand and entire forearm into the abdominal cavity through the vagina. In order to furnish enough space for this purpose it is imperative to cut through the mucous membrane of the vagina its whole length on each side postlaterally. The mucous membrane being severed, the other structures will stretch at once. The bare arm, being smeared over with sterile vaselin, glides in with ease. He has within the last three years passed his hand through the vagina to the diaphragm, and palpated all the abdominal organs. In one case, after detecting gallstones, he cut down upon the gall bladder and pushed it, full of biliary calculi, through a buttonhole incision in the abdominal wall. In another case, a cancer of the rectum, he passed his hand and detected cancer of the liver and gall bladder. In a third case the vaginal outlet was so small that a digital examination could not be made without an anesthetic. He found cancer of the posterior lip of the cervix. He passed his hand through an anterior colpotomy, after having slit the vagina on each side, and found a hard tumor, evidently cancerous, on the anterior surface of the stomach. The lymphatics were also extensively invaded.

DISCUSSION.

DR. R. C. COFFEY asked under what circumstances the essayist would make such an exploration as he had described, inasmuch as the vagina can not be thoroughtly sterilized, and since an abdominal incision is fraught with so little danger.

DR. A. L. WRIGHT spoke disparagingly of this method of exploration. He questioned the possibility of being able to render the vagina aseptic. The method impressed him as being much more formidable, and attended with more danger than an abdominal incision.

DR. C. O. THIENHAUS called attention to the method employed by Ott, who introduces an electric light through the vagina into the abdomen, at the same time using one on his forehead, with which he can explore the abdominal cavity and see diseases with the eye which can not possibly be diagnosed otherwise, and are dealt with accordingly.

Peritoneal Adhesions, Their Cause and Prevention.

Dr. Arthur E. Hertzler, Kansas City, Mo., studied peritoneal adhesions by means of a small glass window sewed into the lateral abdominal wall of an animal. Peritoneal surfaces may agglutinate without a destruction of the endothelial layer. In true adhesions the endothelial layers are always destroyed. If the basement membrane is not destroyed, the adhesions may separate after a time. If the basement membrane is destroyed, the union is formed by a true growth of fibrous tissue, and is permanent. Ordinary adhesions are formed by fibrin formation, with a loosening of the cement substance of the basement membrane, and an interlacing of the fibers forming the basement layer. This forms in from twelve to eighteen hours. The formation of peritoneal adhesions depends on the same factors as does blood coagulation. The irritation of the surface destroys the endothelium, permitting the escape of fibrinogen-forming fluid. The CaCl is abundant immediately below the endothelial cells, as may be demonstrated with silver nitrate. The escape of the leucocytes from the vessels activates the proferment, and makes it active. The precipitate of fibrin thus formed is identical with that formed in blood coagulation, as may be demonstrated by the fact that those factors which prevent coagulation also prevent peritoneal adhesions. The agents most employed are phosphorus and peptone. The former prevents the formation of adhesions by destroying the fibrinogen, the latter by acting on an antiferment. The presence of a digestive ferment in the upper intestinal tract explains why adhesions form less readily in spontaneous perforations in this region.

(To be continued.)

SOUTHERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

(Continued from page 1988 of last volume.)

Unveiling Exercises.

The monument erected by the association to its founder, the late Dr. W. E. B. Davis, was unveiled in Capitol Park with fitting ceremonies, December 14, at 11 o'clock, in the presence of about 5,000 people, including the members of the association. After an invocation by Rev. Dr. L. S. Handley, Dr. Charles M. Rosser of Dallas, Texas, was introduced and delivered the address of presentation of the statue. The statue was unveiled by Elizabeth and Margaret Davis, the little daughters of the beloved physician. Dr. R. M. Cunningham, acting governor of the state of Alabama, accepted the statue in behalf of the state in an eloquent address in which he paid a glowing tribute to this great physician. The statue, in behalf of the city of Birmingham, was accepted by Hon. John C. Forney, the representative of Mayor Drennan, who was unavoidably absent.

A Method of Uniting Intestines of Very Small or of Unequal Caliber.

Dr. J. Shelton Horsley, Richmond, Va., said that modifications of sutures may be divided into two general classes, the continuous and the interrupted. Taking it for granted that each suture penetrates all coats of the intestines, he demonstrated experimentally that the continuous suture more nearly fulfills the ideal conditions for intestinal healing than the interrupted suture. Serous surfaces unite after being sutured, on account of the hyperemia of repair, and this is dependent on some slight injury to the peritoneum. In the case of an interrupted suture, union is obtained within the bite of the suture, by hyperemia caused by pressure of the suture, by the trauma of the needle, and by the presence of the thread. Between the sutures the pressure from thin intestinal tissues is practically *nil*, so union depends solely on extension of this hyperemia, and if this process does not extend from one stitch to another, leakage will surely occur. If continuous and moderate pressure is made on two serous surfaces, sufficient injury will be done those surfaces to cause adhesions. This continuous pressure along the entire margin of an intestinal wound can be obtained only by the continuous suture.

He described nine experiments in which an area of intestine was included between two lines of sutures. In only four of these did the whole area between the rows of sutures unite, demonstrating that something beside mere approximation of serous surfaces is necessary for satisfactory union. The intestinal ends to be united are placed side by side with their convex borders in contact and clamped with a hemostatic forceps. Then he uses a suture that passes through the whole of the intestinal wall, sewing together with a continuous stitch a crescentic area excised; then, changing the stitch to a Cushing right-angled continuous suture penetrating all the coats and invaginating the remaining margins of the wound. When the first knot is reached in the suture, it is invaginated, and the suture continued by two or more insertions of the needle; with the last two insertions as secure a hold as possible is obtained without penetrating the mucosa. The very last insertion of the needle is in the reverse direction of the other insertions, so that when the knot is tied it is partly buried. The bowel is then returned to its natural position, and the mesentery sewed up with continuous stitches.

DISCUSSION.

Dr. W. P. Carr, Washington, D. C., stated that the holding of the bowel with a clamp, a rubber ligature, or tape to prevent the escape of intestinal contents during operation is the only part of intestinal suture that seems not to be as perfect as it might be. There is more or less danger of injuring the bowel by a clamp or ligature which is put around it tight enough to prevent the intestinal contents from escaping. The Murphy button or any form of clamp might possibly do this at times, particularly if the bowel is already more or less inflamed at the time of operation. He thinks it is better to have an assistant hold the bowel with the fingers when this is possible, although it facilitates the operation very much to take the bowel in a long clamp not far from the point where it is going to be sutured, as it prevents the sliding of the coats of the bowel over each other.

Dr. Herman J. Boldt, New York City, prefers suturing to using buttons or mechanical devices.

Dr. J. M. T. Finney, Baltimore, has found that there are certain technical difficulties to the end-to-end suture which are hard to overcome. For example, at the mesenteric border it is difficult to obtain satisfactory union; there is so much likelihood that a leak will occur there, that it has been his practice for the last two years to use, almost exclusively, lateral anastomosis, closing both ends. This gives more satisfactory union. He advocates the interrupted suture.

Dr. A. Palmer Dudley, New York City, uses the continuous suture and has obtained good results.

Dr. W. S. Goldsmith, Atlanta, Ga., believes that in placing continuous sutures around the bowel, where there is likely to be distention, leakage may result, and a fistula be produced by tissue necrosis incident to bowel distention on account of the application of this ligature. He prefers the interrupted suture, although not so rapid for use, thus minimizing the pressure owing to distention or dilatation of the gut.

Dr. Samuel J. Mixter, Boston, said that the continuous suture is quicker. He emphasized the necessity of everybody practicing these operations on lower animals before doing them on patients. Every new method should be tried on the lower animals. He thinks very little clamping is necessary, even if there is some leakage. He does not consider that there is any great danger from septic peritonitis following, because the peritoneum is able to stand a great deal of soiling without much damage, and it can be washed off without producing any ill-effects. This is likewise true of operations on the stomach.

The Abuse of Purgatives Before and After Abdominal Section.

Dr. I. S. Stone, Washington, D. C., said that purgatives should be given as evacuants and should not produce hypercatharsis, whether administered before or after abdominal section. The excessive purgation hypercatharsis commonly employed is intended not only to empty the bowels, but to perform additional service, namely, to remove collections of serum or other fluids which may be in the peritoneal cavity.

A large majority of the sections made at the present time may be called minor pelvic or minor abdominal. In these no infection exists nor is the intestine in any way involved. Such cases require only the mildest evacuants, with sterile diet in the preliminary treatment. Vomiting, paresis, ileus, and excessive distension of the abdomen after operation are frequently exaggerated and aggravated by the administration of the worse than useless cathartics which are usually given. No remedy has been discovered for vomiting due to anesthesia, and this fact should interdict the annoyance given patients by using purgatives before normal peristalsis has been restored. The only remedy of value for vomiting is the regulation of stomach contents, both as to character and quality of substances ingested. It has been shown that patients have bowel movements after surgical operations because they are ready to act rather than because one has found any method to produce such results. Hypercatharsis does more than anything short of venesection, or the use of dangerous heart depressants, to unfit patients for prolonged anesthesia and operations. The prompt administration of purgatives after operation appears to cause vomiting and reversed peristalsis, and adds to the general discomfort of the patient. If the intestines are not actually scoured by catharsis and have only been fairly well emptied of excess of gas and fecal matter, they will respond to treatment after operation with far greater ease than when made absolutely empty.

A Review of the Treatment Immediately Before and After Abdominal Section.

Dr. L. S. McMurtry, Louisville, said that the general indications for preparatory treatment in cases of abdominal section were to cleanse the alimentary canal thoroughly without violent disturbance or exhaustion, to put all the eliminative functions in the best possible condition, and to favor in every way a tranquil state of mind and body. More than a year ago he became satisfied that to put the patient to bed for three days, or even longer, as was practiced by many, was not the best course of preparatory treatment. There is a positive advantage in having the bowels cleaned out in a relatively short time, as the patient is not relaxed by purgation and is less prone to suffer from toxic changes. Prolonged and irritating catharsis increases the nausea and vomiting of ether and of chloroform anesthesia. A prolonged period of preparatory treatment impairs the patient's strength and depresses the nervous system.

In the cleansing and disinfection of the skin we must accept at the outset the established fact that sterilization of the skin from a bacteriologic standard is impossible; yet mechanical cleansing will, for all practical purposes, free the skin of all active germ action and provide for immediate primary union of wounds. In the effort to accomplish this the important fact has been overlooked that the unbroken skin is endowed with a power of resistance to the activity of its own and other germs, and when the epidermis is cracked, denuded and broken by irritating germicides and scrubbing with hard brushes, this natural resistance is impaired and infection occurs. Mechanical cleansing will remove germs readily from smooth and unbroken cutaneous surfaces. For these reasons the brush and chemical germicides should be discarded and only soap and water and alcohol should be used, applying these with gauze instead of the brush.

In the after-treatment only the most simple course is necessary in average cases. The routine use of purgatives is to be avoided. The patient should be allowed to move about in bed freely, and should be given water as soon after operation as it can be retained.

The Employment of Celluloid Plates for Covering Openings in the Skull in Operations for Epilepsy, Brain Tumor, Etc.

Dr. William P. Nicolson, Atlanta, Ga., summarized this subject as follows: 1. Celluloid is safe and does not add any extra risk to the operation. 2. It not only removes the pressure and irritation which the surgeon is endeavoring to combat, but by its resistance prevents a recurrence from the subsequent consolidation of the coverings in a false position due to atmospheric pressure. 3. It protects the patient from external influences, and not only makes him feel safer, but he is actually safer. 4. It enables surgeons to be much more untrammeled in the amount of bone that they can remove. 5. It prevents deformity, which especially, when beyond the hair line, is necessarily great in large bone removals.

Traumatic Synovitis of the Knee Joint.

Dr. Edward A. Balloch, Washington, D. C., cited illustrative cases showing the advantages of early operative intervention, after which he drew the following conclusions: 1. In most, if not all, cases of traumatic arthritis of the knee there is an injury to some of the structures of the joint. 2. Conservative measures should not be persisted in too long. Three weeks was proposed as a fair length of time for a trial of these measures. If no improvement is manifest at the end of that time, the propriety of operative intervention should be considered. 3. Arthrotomy, properly performed, is not an essentially dangerous procedure and may do great good. 4. Early operative intervention will give a greater proportion of useful joints in a shorter space of time than will any other method.

Cases in Which Early Diagnosis of Cancer of the Uterus Was Made.

Dr. Rufus B. Hall, Cincinnati, said that of the many cases of cancer of the body of the uterus coming under his observation only two cases, which he reported in his paper, were seen early enough to make a diagnosis while the disease was limited to a very small area. Adenocarcinoma was found to be the variety of the disease in each case. He believes that the disease can be diagnosed in its incipiency if surgeons systematically curette every suspicious case and make repeated microscopic examinations of the scrapings removed from the uterus until they confirm or disprove the presence of malignant disease.

A Contribution to the Origin of Adenomyoma of the Uterus.

Dr. J. Whitridge Williams, Baltimore, after calling attention to the anatomic appearance of adenomyomata of the uterus, and to the various theories which have been advanced according to the origin of the epithelial structures contained in them, described a uterus removed at autopsy from a woman who died just after delivery as the result of hemorrhage from placenta previa. At the time of its removal the uterus apparently presented the characteristic appearance of the organ immediately following delivery, except that the area of placental attachment covered two-thirds of its interior, instead of being more circumscribed and limited to the anterior or posterior wall, thus indicating in all probability that interference with its blood supply had led to a much more extensive implantation of the placenta than usual.

On making a sagittal section through the uterus after hardening, numerous irregularly shaped, more or less oval areas, of a dull white appearance, and varying from a millimeter in diameter to structures 5 by 10 mm. in their various dimensions, could be seen throughout the entire thickness of the uterine walls, which measured 3 cm. in their thickest parts. These areas were most abundant immediately beneath the endometrium, but could be traced outward through the entire thickness of the uterine wall to its peritoneal covering. On microscopic examination they were found to consist of typical decidual tissue, which was made up of the characteristic decidual cells and glandular spaces lined by cuboidal epithelium. Dr. Williams stated that, so far as he could ascertain, this is the first case in which such a distribution of decidual tissue has been observed, and then discussed the importance of such an observation in contributing toward determining the derivation of the epithelial structures contained in adenomyomata. He referred briefly to the literature on the histogenesis of adenomyomata and pointed out that while the vast majority of such growths are clearly derived from Muellerian tissue, conclusive evidence against the Wolffian body origin of certain cases has not yet been and probably never can be adduced.

Development of Fibroids of the Uterus After Ablation of the Appendages.

Dr. J. Wesley Bovée, Washington, D. C., stated that the large number of published cases of fibroid tumors that have undergone malignant degeneration, or that have broken down, become infected, or undergone other changes in structure detrimental to the lives of their unfortunate possessors, have swept away the old ideas as to their benignancy, and that pathologists are now searching for a distinct borderline between benign and malignant soft uterine myomata. Recurrent myomata, while not so dangerous as cancer, must be considered malignant. Between these and sarcomata there is not always a distinct difference. Dr. Bovée cited five cases, and of these two were operated on for non-infectious disease, two were victims of infection and in one a condition requiring the removal of the appendages was not known.

In considering the changes in the uterus after ablation of the appendages, Dr. Bovée quoted the experimental work on lower animals of Hunter Robb and others, and said that from these experiments and investigations one can find but one theory on which to base a cause for the development of fibroids after double salpingo-oöphorectomy. This is the endarteritis obliterans noted by Benckeiser.

The Effect of Suspension of the Uterus on Pregnancy and Labor.

Dr. Joseph Taber Johnson, Washington, D. C., contended that very few, if any, such injurious effects need be feared as have been frequently charged against this operation. In over 100 suspensions done by himself he only knows of two pregnancies. These were both normal. In one case the labor was so rapid that the child was born before the physician's arrival, and he knows from recent examinations that there has been no return of the retroversion. The other case he delivered in November last after a five hours' normal labor, without chloroform or forceps.

Typhoid Fever and Appendicitis.

Dr. John C. Oliver. Cincinnati, draws the following conclusions: 1. That typhoid ulcers may appear in the glandular structures of the appendix and give rise to a typhoid appendicitis. 2. That the infiltration of the ileum and cecum in typhoid fever may be so great as to give rise to a distinct tumor mass in the right iliac fossa. 3. That the Widal test is of but little, if any, value in the early diagnosis of the disease present. 4. That the leucocyte count proved in his series of cases to be of value in distinguishing between the two diseases. 5. That an exploratory laparotomy in typhoid fever is not devoid of danger. 6. That abdominal incision is imperative when it becomes necessary to establish the differential diagnosis between a typhoid perforation and fulminant appendicitis. 7. That in the absence of perforation cases of typhoid appendicitis should not be operated on.

Gynecologic Problems.

Dr. P. F. Chambers, New York City, read a paper in which he pointed out the problems presented to the gynecologist twenty-five years ago and to-day.

The Management of Acute General Peritonitis.

Dr. J. Garland Sherrill, Louisville, Ky., considered two forms of infection: First, acute septic peritonitis; second, general suppurative peritonitis. The various methods of medical treatment were considered, and the position taken that these cases are surgical, except where operation is refused and the patient's condition will not permit of surgical interference.

In considering the surgical treatment he placed much stress on early operation for the prevention of general peritonitis while the process is yet localized. The outcome of a given case will depend on the following factors: 1, the virulence of the infection; 2, the quantity of the infecting medium; 3, the resistance of the patient; 4, the activity of the organs of elimination; 5, the time at which the patient comes to operation; 6, the rapidity and thoroughness of the surgical procedure.

Dr. Sherrill considers that the special technic of the operation is of less importance than the dexterity of the surgeon and the care with which he does his work. He finds that by flushing he can best free the peritoneum of infectious material, and usually drains. The patient should have the usual treatment given all abdominal cases.

Some Further Advances in Renal Surgery.

Dr. John B. Murphy, Chicago, made a forcible plea for more conservative surgical work on the kidneys and ureters in the future, saying that surgeons must consider the importance of preserving any portion of a kidney that is still in a condition to functionate, on account of the enormous mortality associated with the removal of this organ. The mortality in the past following the removal of a kidney that was secreting practically the normal amount of urine varied from 29 to 35 per cent. He reported six cases of operations on the kidney. In all of them the enlargement of the pelvis of the kidney was almost equivalent to, and in many instances larger than, the kidney itself. In cases of great dilatation of the pelvis of the kidney it was his custom to remove the kidney until he realized that it was practically a normally secreting organ and that the dilatation of the pelvis is due to ureteral obstruction, and that there is no good reason for taking out a kidney when the sac is removed, regardless of the position of attachment of the ureter to the sac, as this varies in every case. He believes in connection with surgery of the kidney that surgeons are approaching a time when they will examine the kidney carefully and cautiously and then decide, as in certain lesions of the stomach, that this or that portion shall be removed and the remaining part husbanded.

Vesical Diverticula Requiring Operation.

Dr. Hugh H. Young, Baltimore, stated that a patient died after obscure bladder symptoms, and autopsy showed seven diverticula, the largest about five inches in diameter, communicating with the bladder by small orifices. Both ureters were compressed by the diverticula, and hydroureter and hydropelvis resulted. The patient died of uremia. Since then he has had four cases of vesical diverticula where operation was advisable, and was performed with success in each case. In two cases the diverticula were larger than an orange, in the others smaller.

His four patients are all living and in good condition. In three cases the diverticula were completely excised, but ureteral transplantation was avoided by a plastic method. Renal infection was avoided and no fistulæ resulted.

The Ultimate Results Obtained by Conservative Perineal Prostatectomy in Seventy-Five Cases.

Dr. Young also read this paper. In this series there were 5 cases over 80 years of age, one 87 years of age, with one death five weeks after the operation in a man aged 84. Two other deaths, neither attributable to the operation, occurred, each in the third week, one, in a patient walking about and ready to go home, from pulmonary thrombosis, and the other in a man 77 years of age who had been uremic for several weeks, and autopsy showed double pyo-hydro-nephrosis. The harmlessness of the operation was thus shown.

When Shall We Resect in Tuberculous Disease of the Joints?

Dr. C. H. Caldwell, Cincinnati, in a paper on this subject, stated that his judgment as to the advisability of resection in a given case of tuberculous joint disease would be influenced by many considerations. A single tuberculous focus in the epiphysis of a long bone, which is susceptible of complete immobilization, stands a much better chance of undergoing reparative change than will such a focus in the spongy bones of the wrist, in the close proximity of synovial and ligamentous structures which favor dissemination and persistence of the disease. The conservative treatment of joints was discussed at considerable length and was divided into three classes—ideal, satisfactory and unsatisfactory.

The results from the resection of the hip are of necessity unsatisfactory when complete, as with ablation of the head and neck of the femur, one leaves no *point d'appui* for the femur, and there must be a greater or less amount of give to it under the weight of the body. In tuberculosis of the knee one is confronted with an entirely different problem. There is but little use of wasting time with a knee joint in which marked osseous changes are already present, and which, in spite of conservative treatment over a period of six months, has shown no improvement. Resection of the knee in cases which have passed the period of adolescence has much to recommend it and but little can be said against it. In those cases long delay often means amputation. As to resection in elbow cases, one is again confronted with the fact that results are at the best far from what one may desire. In the wrist and carpal joints excision depends on individual judgment. Ankle joint and tarsal excisions are, as a rule, very unsatisfactory. The deficiency in weight-bearing capacity renders the result far from gratifying and amputation is, so far as his observation goes, too frequent a sequel to these operations. Several skiagrams were exhibited illustrating tuberculous joints and the results of resections.

Obliteration of the Stomach by Caustic.

Dr. Samuel J. Mixter, Boston, stated that doubtless other surgeons have seen cases of constriction of the esophagus after the ingestion of acid or of strong alkalies, and also cases of constriction of the pylorus from the same cause. It is very rare, however, to find practically the whole stomach destroyed. He reported three cases in which the stomach was almost entirely obliterated by caustics.

Vaginal Cesarean Section.

Dr. C. Jeff Miller, New Orleans, reported a case and summed up the advantages of the method as follows: 1. In severe eclampsia, when the woman is unconscious between the convulsions, the cervix rigid and elongated, and delivery imperative, it is always preferable to abdominal section, and, under proper surroundings, may be preferable to metal dilators for manual dilatation. 2. In severe cases of accidental hemorrhage, when the cervix is closed, it is safer than the other method of accouchement forcé, owing to the rapidity with which the uterus can be emptied, and should be given preference over abdominal hysterectomy, which is generally advised. 3. It may be considered in other conditions where cesarean section is indicated, except in contracted pelvis or dystocia, arising from maternal or fetal disproportion. It has not the disadvantages of an abdominal operation in that the peritoneum need not be opened unless hysterectomy is to be preferred for malignancy, and there is less shock than follows abdominal operation. 4. It is not more dangerous than attempting to deliver either by version or by forceps, when the os is not fully dilated, if done under strict aseptic precautions.

Dermoid Cysts and Fistulae of the Sacrococcygeal Region.

Dr. Lewis C. Bosher, Richmond, Va., has operated on seven cases of dermoid cysts for fistulæ of the sacrococcygeal region. After referring to the diagnosis and prognosis, he says that the usual methods resorted to for treating inflammatory fistulous tracts will seldom result in permanent cure. Complete extirpation of the fistula and sac must be performed to prevent a recurrence. It is to be noted that this is not always possible, as in a case reported in the literature by Wette, where complete extirpation would have involved opening the spinal canal, with serious injury to the nerves.

Hematoma of the Ovary.

Dr. Magnus A. Tate, Cincinnati, presented a study of the cases which he had collected from the literature. These cases showed that three periods of life markedly predominate as a predisposing factor in the causation of hematoma of the ovary: First, before or during birth; second, at or near the first menstrual flow; third, early adult or child-bearing period. The age of child-bearing women who are afflicted with hematoma of the ovaries varies from 15 to 40 years, and the left ovary seems to be more frequently affected than the right.

Pathogenesis and Surgical Treatment of Tubercular Peritonitis.

Dr. William E. Stokes, Salisbury, N. C., after dwelling on the pathogenesis of this disease, divided it into four forms—the adhesive, suppurative, tympanitic and ascitic. He quoted extensively from the literature of the subject, referred to the modes of infection, reported a series of cases occurring in his own practice, and spoke of the importance of histologic examinations.

Tracheotomy for Gunshot Wounds of the Trachea.

Dr. J. McFadden Gaston, Atlanta, Ga., discussed the subject of gunshot wounds of the trachea, and the complications that are likely to occur from septic infection or from laryngeal stenosis. He reported a case of gunshot wound of the trachea in a child 8 years of age. The position of the incision in the trachea was lateral rather than on the anterior surface of the windpipe. The patient made an excellent recovery.

Rupture of the Diaphragm.

Dr. George S. Brown, Birmingham, Ala., read a paper on this subject and reported an interesting and instructive case in a fireman, 27 years of age, six feet tall, whose weight was 190 pounds. The patient had hurt or strained his side slightly about two years before the rupture of the diaphragm occurred. Although an operation was performed, the case terminated fatally.

The following papers were also read: Dr. J. A. Goggans, Alexander City, Ala., "Report of Two Cases of Tumor of the Pancreas"; Dr. Herman J. Boldt, New York City, "Treatment of Uterine Bleeding"; Dr. W. H. Doughty, Augusta, Ga., "Suprapubic Prostatectomy"; Dr. W. D. Haggard, Nashville, Tenn., "Encephalo-Meningocele." Dr. Haggard also described an easy method of instituting peritoneal gauze drainage through the cul-de-sac. Dr. J. B. Murfree, Murfreesboro, Tenn., "Strangulated Hernia." Dr. E. Denegre Martin, New Orleans, reported two cases of cancer of the appendix.

Dr. Henry T. Byford's paper, "Some points in the Technic of Aseptic Operating," will appear in full in The Journal.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Regular Meeting, Nov. 3, 1904.

The President, Dr. Richard C. Norris, in the Chair.

Report of a Case of Rupture of the Trachea During Labor.

Dr. Charles A. Service reported this case. In a primipara, aged 29, after labor had proceeded in an apparently normal manner for some time, during a pain, a swelling appeared about the left side of the neck and face. On examination the subcutaneous tissue from the sterno-clavicular junction to the corner of the mouth was found to be emphysematous and painful on pressure. This condition increased with each pain. An anesthetic was administered and delivery effected as speedily as possible. The emphysema finally extended to the entire trunk and both arms, and the eyelids, especially of the left, were distended to the extent of obscuring vision. The swelling disappeared by the eleventh day, absorption being apparently favorably influenced by the application of hot alcohol several times daily.

DISCUSSION.

Dr. Roland C. Curtin reported a case of emphysema of the chest, neck and face during labor which later involved the whole chest except the mammary glands and in which deglutition caused pain and nausea and which was followed by an uneventful recovery.

Dr. E. P. Bernardy said that he had seen a patient's face become swollen and crepitant after a long and difficult labor, but that he had not considered this a condition of fractured trachea.

Dr. Richard C. Norris reported seeing this accident twice.

Dr. B. C. Hirst stated that he had seen one case of rupture of the trachea and that that was a comparatively mild one. The deformity was not great, but the crepitation was marked.

Central Rupture of the Perineum.

Dr. W. H. Nicholson reported this case, which occurred during labor. The rupture was the size of a half-dollar and occurred just in front of the anus. He ascribed its causation to marked overflexion of the head associated with a very narrow symphyseal arch. He considered that there may have been some abnormality in the function of the levator ani which either prevented head extension or did not present enough resistance to produce it. Dr. Nicholson said that the symptoms which would lead one to suspect such an accident are great distension and thinning of the perineum, associated with posterior situations of the presenting part as a whole. He thinks that the preventive treatment should consist in section of the perineum in the median line followed by a delivery of the head by forceps or rectal finger.

DISCUSSION.

Dr. Roland G. Curtin reported a case similar to that of Dr. Nicholson.

Dr. Richard A. Cleemann also reported a similar case. The child was born during his absence, and on examining the patient afterward he found a long jagged tear extending from the anus nearly to the fourchette. The wound was at once closed with silk sutures, but union was followed by a vaginal fistula which closed spontaneously later. Subsequent labors occasioned lacerations, but none so severe.

Dr. H. P. Fisher reported a case in which he averted a tear into the rectum by incising the perineum anteriorly with scissors.

Dr. Daniel Longaker said that he has never seen a central perforation of the perineum, but has frequently seen, coming in advance of the head, a fold of mucous membrane which was starting to tear high up in the vagina and was advancing with the progress of the head.

Dr. G. N. Boyd considers the etiology of the tear a matter of great importance. He has seen a tear commencing as a central laceration finally completing itself before the delivery of the child. He admitted the possibility of the explanation given by Dr. Nicholson of spasm of the levator ani causing this condition.

Dr. E. P. Bernardy stated that central lacerations may be due to several causes, the principal one being malposition of the head, especially posterior presentations. The second cause he regards as the well-known lack of muscular extensibility. The forceps as applied in posterior presentations may also be a cause. He reported an illustrative case.

Dr. R. C. Norris stated that one has to theorize a good deal on the mechanism of labor in such cases, since they happen so infrequently. He considers Dr. Nicholson's explanation not wholly satisfactory. He has noticed that just before the birth of the occiput there is occasionally a sudden giving way of some obstacle to the advancing head. He believes that this release of the head is due to sudden overdistension of the pelvic floor, which allows the head to quickly pass through the vulvar ring. The practical side of the question is that at this stage of labor the obstetrician should see that the head does extend.

Dr. Ncholson stated that the overdistension of the perineum, antedating the true central lacerations, precludes the possibility of mistaking an ordinary case for a central laceration. He thinks it is generally agreed that there should be immediate repair of the injury.

Therapeutic Value of Ergot in Labor.

Dr. J. C. Applegate stated that he does not regard ergot as a safe or appropriate remedy for uterine inertia. Its physiologic effects on the uterus are unlike the rhythmical labor pains in that they are less intermitting, more continuous and predisposed to cause uterine constriction, particularly of the lower segment. He thinks that the dangers attending premature administration of the drug are: Rupture of the uterus. asphyxiation of the child or paralysis of fetal heart from compression, and retention of the placenta and membranes. He believes it better to complete the dilatation manually. He considers ergot indicated as a safeguard after delayed labor, or when inertia has been a factor, after placenta previa, and after reposition of an inverted uterus.

DISCUSSION.

Dr. R. C. Curtin stated that most of the ergot he has given of late has been for other hemorrhages than those of the uterus. In cases where there is general oozing from a mucous membrane he thinks it does good.

Dr. Longaker said that he agreed with Dr. Applegate that several of the most difficult cases of expulsion of the placenta were cases in which ergot had been given freely. He reported briefly two patients who died of postpartum hemorrhage after they were left by the physician. In neither case was ergot used. He thinks that the routine method of completely emptying the uterus and then administering ergot would prevent such calamities.

Dr. W. R. Nicholson stated that ergot instead of increasing the chances of infection has the opposite effect and offers a means of cleansing the uterine cavity in a way not possible by any other means.

Dr. Applegate agreed that ergot may be of great advantage as a preventive against septic infection when there is profuse bleeding or other evidence of a relaxed condition of the uterus. On the other hand, if the uterus is normally contracted, he believes that ergot blocks the secretions and dilates the veins, thus aiding in the absorption of septic material.

Travel Notes.

XXI.

FOUR THOUSAND MILES THROUGH INDIA BY RAIL IN MIDSUMMER.

NICHOLAS SENN, M.D.
CHICAGO.

S. S. Kronprinz Wilhelm, Oct. 11, 1904.

When I decided to make a tour around the world by way of India, during midsummer, I knew beforehand that I would have no use in that part of the world for an overcoat or blankets. I was very well aware of the fact that that part of India which I expected to see had an unenviable reputation as a summer resort. Information from different sources concerning the climate of certain countries is about as reliable as hunting and fishing stories. In order to ascertain about what I had to expect in the way of heat at that time of the year, I interviewed sea captains and people who had lived in India. The opinions expressed were so widely at variance that I remained in doubt concerning the real climatic conditions that I would have to encounter in that part of my itinerary around the world. A traveling companion from San Francisco to Auckland, a missionary, who had lived several years in the northern part of India, gave me the most discouraging account. He said that where he formerly resided the burning sun during summer heated the stones to such a degree of heat that a simple touch with the hand would result in a burn sufficiently severe to blister the skin. An officer of the Indian Medical Service gave me the consoling information that when he was on duty at Calcutta he had to spend several hours each day in a cool bath during the summer months to counteract the intensity of the heat. Sea captains were only familiar with the climate on the coasts of India; they knew nothing about the summer climate of the great plains which I expected to cross. Their opinions on the coast climate were not unanimous. They could be formulated about as follows: Very hot, hot, quite hot, not so bad as has been represented. In view of these testimonies, I approached the climate of India with a mixed feeling of hope and fear. After having crossed the equator twice on the way from

San Francisco to Ceylon, I spent five days in the hot, humid climate of Ceylon, and for the first time fixed my eyes on "India's Coral Strand" early Tuesday morning, August 30. From subsequent experience. I would suggest the following change in the second line of the famous and well-known missionary hymn:

From Greenland's icy mountains
From India's "burning" strand,

as this change would more forcibly indicate the difference in the climatic conditions of these two places which these lines are intended to convey. The first impression of India in landing at Tuticorin is very disappointing. Unlike the South Sea Islands and Ceylon, the coast is not fringed with palm trees; it is bare and barren. The country is level and vegetation very scanty. The part of India which I traversed, and the tour extended from Tuticorin to Bombay. via Madras, Calcutta, Benares, Allahabad, Agra, Delhi, Jaipur and Ahmehabad, is entirely devoid of interesting scenery. There are no forest-clad mountains, waterfalls, mountain lakes, babbling springs nor clear rivers. Most of the river beds are dry or are a succession of dirty pools, the favorite bathing and drinking places for man and beast.

The sacred Ganges at Benares is about the size of the Mississippi at St. Louis. It is the great sewer for millions of people; its dirty water is credited with great healing power by the superstitious population and is carried in earthen or brass vessels, or pigskins, great distances for drinking purposes. as it is supposed to possess virtues which will prevent and cure all kinds of diseases. When we realize that the river is used as a receptacle for corpses, dead animals and everything that is filthy, it is difficult to comprehend how Mark Twain could come to the conclusion that its water is the purest in the world and sing its praises. This great traveler has immortalized himself with the natives of India by lauding the purity of the Ganges water. He may be right from a bacteriologic standpoint, and his position would be upheld by the Chicago Department of Health, but would meet with violent opposition by the guardians of health of the city of St. Louis.

When I saw this sacred stream its water was about the color of pea soup, and during a boat ride along its shores I saw a number of decomposed, bloated dead dogs floating on the surface of the sluggish stream, and at the place where the corpses of human beings are cremated baskets of ashes were consigned to its sacred water. The soul of the Hindu finds no rest until at least a part of the incinerated remains are deposited in this river. From the ashes of the cremated bodies a few fragments of bone are taken, tied up in a cloth and sooner or later this ghastly bundle must be thrown into the Ganges, even if this part of the funeral rites requires days and weeks and no inconsiderable expense incidental to the travel. It is fortunate that this river is inhabited by crocodiles, which can dispose, at least, of some of the bodies and carcasses which are thrown into it by the hundreds and thousands every day. In the inhabited parts of the country through which the Ganges passes, its shores are lined with washerwomen and washermen and human and animal bathers. The amount of human excreta which find their way into this stream is simply enormous, and other sources of pollution are innumerable; hence, if nature's laboratory can cope successfully with so many sources of contamination and render the water. if not clean, yet potable and bacteriologically pure, she has done what sanitarians so far have failed to accomplish.

I have said that the part of India included in my tour lacks scenic beauty. It is monotonous, a great, level, limitless plains. covered by rice marshes on the west coast; deserts. pastures. grain and cornfields in the interior and along the Indian Ocean coast; very little fruit culture anywhere. Between Madras and Calcutta. and in the vicinity of Jaipur. the monotony of the landscape is somewhat relieved by mountain ranges. which are. however. almost bare. dotted only here and there with clumps of shrubs and dwarfed. hardy. much-branched trees.

Water is India's greatest concern. On the amount of rainfall depends the success or failure of the crops.

> "All the results of agriculture are dependent not so much on reason and diligence, as on those most uncertain things, winds and weather."—Cicero.

Deforestation has impoverished India, as it has the Holy Land, Greece, Turkey, Spain, southern Austria, and parts of the United States. The building of reservoirs and dams to hold heaven's gift have succeeded only in part to prevent drouths when the rainfall is scanty. The government has at last recognized the true cause of the frequent drouths, and in 1880 passed laws prohibiting further forest destruction, and took active steps to restore what has been lost by the reckless, thoughtless, destructive work of man. The results of the efforts of reforestation are apparent in many parts of the country, and if this good work is carried on with the deserved energy, India will get its good share of rain in less than a hundred years; the farmer will reap, from year to year. the rewards of labor, famine will disappear and the general prosperity of the country will reach a degree never known before. Nature has made provision for reforestation of arid regions. In the desert of Sahara, along the banks of the Suez Canal, I noticed a shrub from 4 to 8 feet high, with a dark green foliage—the *Tamarix tetragyna*—in places where nothing else would grow. This shrub is preeminently fit for dry saline soil. The leaves are eaten by cattle. This shrub would flourish in the deserts of our western states.

At present the laboring classes spend much of their time and labor in holding and distributing the limited water supply. In some districts the government has established well-planned systems of irrigation, which have brought millions of acres of arid land under successful cultivation. Beyond these areas, the farmer, during the dry season, spends most of his energies in supplying the arid soil with moisture by the most primitive methods. From pools, tanks and wells, water is drawn in pails by hand, foot or bullock power, in the same way as was done a thousand years and more ago. I never saw a windmill in India. The water is poured into little gutters. which intersect the fields in different directions. Men, women and children are engaged in this kind of work. The women supply the household with water and, as the wells are frequently far apart, this task is often not an easy one. Hard as this work may be, it has its fascination for the women. They congregate at the well, chatter and laugh while the earthen or brass vessels are being filled, and, when perched on their well-balanced heads, return in files to their village, keeping up their lively conversation until the one from the greatest distance finds herself alone. The erect, graceful stature of the laboring native women is largely due to this enforced useful gymnastic exercise.

A common way of dipping water from a tank or pool into an irrigating ditch is by means of a large waterproof basket made of palm leaves, to which is attached a piece of rope on opposite sides. Two persons swing this basket so regularly and skillfully that it catches the water on one side and discharges it on the other. To maintain the proper *tempo* of these swinging movements between the two persons so employed, a monotonous chant regulates the muscular movements. Pumps appear to be unknown. When bullocks take the place of man power, the water is drawn from the well in an immense bucket, the traction rope running in the groove of a wheel about two feet in diameter. The bucket is swung in the desired direction by a man and emptied. The bullock's work is not so easy as it might seem. The run is a short one and the animal is not a very lithe one. and the constant turning movements must be much more fatiguing than the traction in a straight direction over such a short distance.

The elevation of water from a well by a beam, kept in motion by up-and-down movements by the to-and-fro walking on it of one or more boys. can not be regarded in the light of a childish play. The actors must be sure-footed in walking back and forth on the polished beam. and when the exercise is kept up for hours the muscles of the legs and back have certainly undergone a great strain, and when this work is done under the burning rays of the sun, it means a bodily exertion which would exhaust the strength of our best athletes in a surprisingly short time.

ATTRACTIONS OF INDIA.

I did not go to India with the expectation of seeing enchanting scenes, hence I was not disappointed at their absence. I had seen most of the finest scenery in the world, including Alaska, Yellowstone Park, Yosemite Valley, Switzerland, Norway, Tyrol, Siberia, West Indies, Central America, Tahiti, etc., and I came to India to see what is generally recognized as the most interesting country in the world. I came to India to see her people, temples, palaces, tombs, her works of ancient art, her trees, flowers and animals. Having seen as much as possible of these things during the short space of eighteen days, traveling at the same time more than 4,000 miles by rail and during the worst season of the year, I feel fully compensated for the risks incurred and the sufferings endured, and can only repeat what has so often been said, that the real traveler, not the sightseer, will find here more that will interest him than in any other country in the world.

Take away from the Holy Land sacred history and its remaining landmarks, and it could furnish no such attractions as can India, the land of ancient history, civilization, art and science. The tombs and pyramids of Egypt are modern when compared with the ancient temple ruins in India. The history of Rome is as of to-day when contrasted with the records of India, punctured indelibly in characters on the palm leaves used as writing material for thousands of years, and carefully preserved in the temples, which are practically fireproof, and many of them never touched by the rude hand of war and plunder. The ancient history of Egypt must be studied, not in Egypt but in the British Museum, while to become familiar with the earliest history of India, it must be studied in India itself. India has landmarks in history that can not be transported like Cleopatra's needle, landmarks that would be ruined and made valueless if they were taken from the places where they were built thousands of years ago. People from all parts of the world may be seen at a world's fair exhibition, but it is impossible to know them or to learn their habits and customs, their vices and virtues until they are seen at their houses, at their places of business, on their farms, at their public amusements, in their own environments. A native in a distant strange land on exhibition is no more of a native than is a lion in a cage to be compared with a lion in the deserts of Nubia.

And, after all

> "The greatest study of mankind is man."—
> Pope.

The average tourist wants to see beautiful scenery, to walk picture galleries, to attend operas and concerts, to get a glimpse of and, if it is at all possible, to come in touch with royalty or with persons of high positions and social influence. The true traveler, on the other hand, spends much of his time among the mass of the common people, the backbone of every nation. He is anxious to learn from his own observations what they do and how they live. He sees them work in the fields and he visits them in their huts. He visits the markets to learn what the country produces, and he ascertains the prices of foodstuffs. He studies the habits and customs of the people, their clothing, their implements of agriture and war and the tools of the artisans. He looks into the little shops and finds out what the people buy and sell. He makes a study of the trees, flowers and animals, domestic and wild. He frequents the botanic and zoologic gardens and museums. He takes special interest in the landmarks of history, ancient and modern, and the educational advantages and religious beliefs of the natives of the country he visits. With such objects in view, there is no country in the world that offers a wider field and a richer material than India.

MY SERVANT, LAZARUS.

As I have indicated before, travel out of season in a tropic country offers advantages as well as disadvantages. Crowding on shipboard, in railway carriages and in hotels is avoided. There were only twenty first-class passengers on the voyage from Adelaide to Colombo, four from Colombo to Tuticorin and less than fifty from Bombay to Marseilles. At Madras, besides myself, there was only one guest in the Connemara Hotel; at Calcutta, in the Great Western Hotel, not more than ten; at Benares I had the Hotel de Paris to myself, so at Agra the Metropole, and at Delhi the Laurie Hotel, and at Jaipur, in the Rastum Family Hotel, besides myself, there was the Parsee woman doctor who will be referred to again further on. At Bombay, the magnificent hotel Taj Mahal, with 600 rooms, had less than sixty guests at the time of my visit. The Indian railways provide well for the first-class passengers. The first-class compartments have six sitting and four lying-down places, lavatory and a connecting small compartment for servants. Towels and bedding are carried by the passengers. During the six nights I spent on the train I shared such a convenient compartment only once with a fellow traveler, and during the day I was very seldom disturbed by additional passengers. I was never obliged to check my trunk, which was always brought into my compartment. All trains carry ice and soda; the former is sold at 4 cents a pound and the latter at current prices. The trains make a stop of from 25 to 30 minutes at the eating stations at the usual meal hours observed in India.

In undertaking the trip through India at such an unseasonable time, I felt, for the first time in my life, the need of a personal attendant to relieve me of unnecessary care and physical exertion, and on its completion I had every reason to be satisfied with the step I had taken. To pack and to unpack, in a temperature ranging between 92 and 105 F. every day or two and to take care of the baggage and bring it from station to hotel and from hotel to station in such an uncongenial climate, are tasks that should be avoided by the traveler and assigned to a coolie. At Colombo I engaged Lazarus, a Ceylonese Tamil, about 26 years of age, who was to accompany me as my servant from there to Bombay The understanding was that I should pay his transportation both ways, third-class, and that he should receive a rupee and a half (48 cents) a day. The whole expense for the required time amounted to $35.66.

Lazarus was a typical Tamil, slender, lithe, coal-black, with sharp, rather intelligent eyes. He had a wife and two children and lived near Colombo. He inherited the Roman Catholic faith and whenever we visited a Catholic church he sprinkled himself with holy water and made the sign of the cross. A closer acquaintance with him, however, threw some shadows on the religious life of this member of the Roman Catholic faith. His greatest failing was in money matters. Our accounts did not always agree, but, as the amount was usually small, his bills were generally passed and paid; however, as this was a daily affair, I am satisfied that some rupees, many annas and much copper found their way into a corner of his soiled handkerchief instead of back into my pocket. I have learned by a somewhat expensive experience that a pigmented skin abhors truth and cherishes to represent things in the wrong light, and that whether yellow or black its owner, heathen or convert can seldom be depended on. I have learned to comprehend why the Devil, the father of lies, when pictured, is usually made to appear in black. Questionable as the little transactions of Lazarus may have been, his services proved invaluable and, in the end, I was the gainer so far as expense was concerned. He was a very good servant. I could not lose anything if I tried. Things that I threw aside he would pick up and repack.

Lazarus had many unpleasant functions to perform. Tipping is the curse of the traveler. This nuisance has reached greater dimensions in India than in any other country. Tipping in out-of-season travel grows as an unavoidable evil in proportion as the number of visitors is diminished. In hotels and at railway stations the number of employes far exceeded the demand, and as I was so often the only guest or first-class passenger, all eyes and hands centered on me. I made Lazarus my agent in the distribution of tips. It was he who converted large silver coins into smaller change, silver and copper. The coolies did not like to deal with me in such an indirect way, but the rule was an inflexible one and was adhered to from the beginning to the end of the trip. It was by this method of disposing of the tip nuisance that both I and Lazarus made money. The coolie, ignorant as he may be, has learned to distinguish between silver and copper and hates the sight of the latter. To pass through India with honor in the estimation of the coolie, it is necessary to carry a liberal supply of silver coins and to see to it that not too many get a hold of your baggage, as the carrying of an umbrella or cane seems to entitle the bearer to the same financial consideration as is tendered to the one who groans under the weight of the trunk. Lazarus was a source of the greatest comfort to me. He would inform me when to prepare for the next eating station and when the time came to change cars or the approach of the station where I wished to interrupt the journey. He brought me ice and soda whenever I was tortured by thirst, which was often the case. He was master of the Tamil, Singhalese and Hindustan languages, but his knowledge of English was very limited. This was perhaps on many occasions desirable, as he was very loquacious, like all his countrymen. He would often discourse at length, but at the end I did not know in what language. Some of his pigeon English was amusing. In looking at some wild peacocks one day, he wanted to point out the bird with the brightest plumage, and did so by calling him "man peacock." His pronunciation of any of the common English words was so defective that they were absolutely unintelligible. I had held out to him from the very beginning the inducement that if his service should prove satisfactory at the end of the trip he would receive, besides his daily wages, some gold, and in this I did not disappoint him when I bid him good bye at the Bombay dock.

(To be Continued.)

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Acute Laryngeal Catarrh.

In the treatment of this affection in adults, Yeo, in *Clin. Ther.*, states that small doses of opium are advantageous in the early stages in allaying the irritation and in relieving the cough. It is of service combined as follows:

℞.	Morphinæ acetatis	gr. ii		12
	Antimonii et potassii tartratis	gr. iss		09

M. Fiant chartulæ No. xvi. Sig.: One powder every four or five hours.

Heroin is also of value in relieving the tickling cough and the soreness in the larynx combined as follows:

℞.	Heroin hydrochlor.	gr. ss		03
	Terpin. hydratis	gr. xxx	2	

M. Fiant capsulæ No. xv. Sig.: One capsule every three or four hours.

Warm alkaline drinks should also be recommended in thinning the mucus which is sometimes very tenacious and hangs about and partially obstructs the glottis, rendering it difficult to expel. For this purpose the author recommends Apollinaris water to which one or two tablespoonfuls of hot milk should be added and the entire amount drunk. This should be repeated every two or three hours. The following mixture may be substituted for this:

℞.	Sodii bicarb.	ʒi	4	
	Sodii chloridi	gr. xxx	2	
	Spiritus chloroformi	m. xxx	2	
	Aquæ camphoræ q. s. ad	℥vi	180	

M. Fiat mistura. Sig.: Two tablespoonfuls every two or three hours, mixed with an equal amount of hot water or milk.

Ammonium chlorid in 10-grain doses (.60) may be substituted for the sodium chlorid in the above combination.

Counter-irritation and warmth are indicatd by means of small mustard or linseed poultices over the larynx. The following liniment is recommended by the author, rubbed into the throat:

℞.	Olei pini sylves	ʒii	8	
	Linimenti camph. compos	ʒiv	15	
	Linimenti saponis q. s. ad	℥iss	45	

M. Fiat linimentum. Sig.: Apply locally two or three times daily, followed by thorough friction.

Elimination by the bowels by means of saline aperients should be carried out. The voice should be rested and the desire to cough resisted as much as possible.

The following spray is recommended as very efficacious:

℞.	Cocainæ hydrochlor.	gr. iv		25
	Potassii chloratis	gr. lxxv	5	
	Aquæ laurocerasi	m. lxxv	5	
	Essentiæ menth. pip	m. iii		20
	Aquæ q. s. ad	℥viii	240	

M. Fiat mistura. Sig.: To be used as a spray into the larynx.

Inhalations of the tincture of benzoin are indicated, especially in the less acute cases, applied by floating half a teaspoonful of the tincture on a pint of hot water. It is allowed to stand in the patient's room or is inhaled through a funnel. In the treatment of laryngitis in children, hot sponges applied to the neck are recommended and vomiting produced where the mucus is very tenacious, by the administration of vinum ipecacuanhæ minims 30 to 60 (2.-4.) mixed with two or three teaspoonfuls of warm water. Where there is a constant irritating cough, small doses of Dover's powder are advised to relieve the cough. To promote expectoration the following combination is recommended:

℞.	Sodii chloridi	gr. xvi	1	06
	Sodii bicarb.	gr. xxiv	1	55
	Syr. senegæ	ʒiv	15	
	Aquæ q. s. ad	℥iv	120	

M. Fiat misturæ. Sig.: A dessertspoonful, warm, every two hours.

As an expectorant in catarrhal laryngitis in children the following is of service:

℞.	Potassii iodidi	gr. xv-xx	1-1	30
	Syrupi senegæ	ʒiii	12	
	Aquæ q. s. ad	℥iii	90	

M. Fiat mistura. Sig.: One dessertspoonful every two hours.

The following may be used as a spray:

℞.	Cocainæ hydrochlor	gr. iv		25
	Glycerini acidi carbol	ʒi	4	
	Aquæ rosæ q. s. ad	℥iv	120	

M. Sig.: To be used as a gargle three or four times a day or sprayed directly into the larynx.

[Glycerin acidi carbolici contains 20 per cent. of carbolic acid].

Bronchopneumonia in Childhood.

The chief indications in the treatment of bronchopneumonia, according to Stanley, in *Birmingham Med. Rev.*, are to prevent the extension of the disease and to lessen the tendency to blocking the tubules. The child must be kept in bed in a properly ventilated room and placed on a light diet, as milk and barley water, or in older children boiled milk and bread. The following is recommended as an expectorant:

℞.	Vini ipecacuanhæ	m. v-x		30-.65
	Spts. ammon. arom	m. v		30
	Syrupi tolutani	m. v		30
	Aquæ q. s. ad	ʒii	8	

M. Sig.: To be taken at one dose, and repeated every four hours.

In cases of medium severity with a moderate amount of consolidation a pneumonia jacket should be applied and the following prescribed:

℞.	Vini ipecacuanhæ	m. v		30
	Spts. ammon. arom.			
	Syrupi senegæ, āā	m. x		65
	Syrupi tolutani	m. xv	1	
	Aquæ q. s. ad	ʒii	8	

M. Sig.: To be taken at one dose and repeated in four hours.

If there is *no improvement* within thirty-six hours one *minim* of creosote should be added. If the temperature is unusually high, tepid sponging is indicated and the following substituted:

℞.	Liq. ammon. acetatis	m. xv	1	
	Spiritus etheris nitrosi	m. x		65
	Ammon. bromidi	gr. v		30
	Syrupi simplicis	m. xx	1	30
	Aquæ q. s. ad	ʒii	8	

M. Sig.: To be taken at one dose, and repeated every four hours.

If *vomiting and diarrhea* are present, the milk may be discontinued and whey or albumin water substituted. The following combination should be given if the diarrhea proves stubborn:

℞.	Bismuthi salicyl.			
	Sodii bicarb., āā	gr. v		30
	Bismuthi subnit.	gr. x		65
	Pulv. tragacanthæ	gr. xx	1	30
	Aquæ q. s. ad	ʒiii	12	

M. Sig.: At one dose, and repeat in four hours if necessary.

Two grains of Dover's powder may be added to the foregoing if necessary to check the diarrhea. *During* convalescence the patient should be given very nutritious food along with codliver oil or the hypophosphites.

Aufrecht, in Nothnagel's Encyc. of Med., recommends as the most important thing in the treatment of this disease that the patient be placed in a sunny, well-ventilated room and special *attention given to the diet.* Quinin tannate is recommended, given in small doses. Children up to 1 year of age should receive one and a half grains (.09) twice daily, and older children three grains (.20) twice a day. The following combination is also employed in the treatment of this form of pneumonia as in the croupous form:

℞.	Quininæ tannatis			
	Ferri oxydati sacch., āā	gr. iss		09

M. Fiat chart. No. i. *Sig.: One* such powder twice a day, *increasing the dose according to age.*

As to the method of lowering temperature and of increasing elimination, the author advises that a linen cloth or napkin be wrung out of cold water and wrapped around the body of the patient from the back, enveloping the entire thorax, and a dry piece of flannel placed around this compress. The child is then placed in bed and in half an hour the cloth should be changed. By this treatment the respiratory movements become deeper, the sleep is improved, the temperature lowered and the frequency of the respirations and pulse markedly diminished. These improvements are generally shown within ten or twelve hours, when this treatment may be discontinued, to be repeated when necessary, observing at the same time any symptoms of collapse which may occur from too rapid extraction of heat. It is *important to* change the position of the patient from time to time to prevent *stasis in the posterior and* dependent portions of the lungs. *This author recommends baths* only in cases in which there is marked dyspnea, cyanosis and stupor with high temperature. In such cases he recommends a bath at a temperature of from 88 to 90.5° F. for five or ten minutes at a time, followed by effusions of cold water on the neck and back from a moderate height. He condemns the use of emetics except in those cases in which the affection sets in abruptly *inside of from* twenty-four to thirty-six hours with *symptoms of dyspnea and* marked cyanosis. Emetics should not be administered to debilitated *and poorly nourished* children. When emesis is indicated the following combination is recommended:

℞.	Antimon. et pot. tartratis	gr. 1/6		01
	Pulv. ipecacuanhæ	gr. iv		25

M. Fiat chart. No. i. Sig.: One such powder every ten to fifteen minutes until emesis is produced. The use of apomorphin should in all cases be avoided.

Expectorants are very useful *in the course of the affection.* For this *purpose the* author recommends the following:

℞.	*Pulv. ipecac*	gr. iss-iii		09-.20
	Syrupi simplicis	ʒss	2	
	Aquæ q. s. ad	ʒii	8	

M. Sig. One-half this amount at one dose, and repeat every two hours.

Attention is called to the fact, however, that some children possess an idiosyncrasy against ipecac. Even though vomiting may not occur, exhaustion *may ensue and will disappear* with the discontinuance of this' *medicine. As the most suitable sedative* to the irritated mucous membrane the author employs inhalations of steam. When the child is continuously coughing day and night, leading to hoarseness and to exhaustion and sleeplessness, small doses of morphin must be used combined as follows:

℞.	Morphin sulph.	gr. 1/3		02
	Aquæ destil	ʒiiss	10	

M. Sig.: Five drops to a child 2 years of age, repeated *two or three times daily according to indications,* and increasing the succeeding doses to ten or fifteen drops (.65-1.00) if necessary, depending on the effect of the first dose.

In rachitic and cachectic *individuals and in* those cases subject to intestinal disturbances this treatment must be modified. More attention must be given to the diet and alcoholic stimulants added in the form of wine, according to the season.

Pertussis.

The following combinations are recommended in *Clin. Ther.* in the treatment of whooping cough:

℞.	Ext. cannabis ind.	gr. i		06
	Ext. belladonnæ	gr. iii		20
	Spiritus vini rectif.			
	Glycerini, āā	ʒiss	6	
	Aquæ q. s. ad	℥iii	90	

M. Fiat mistura. Sig.: One-half to one teaspoonful *at a* dose, night and morning, depending on the age of the patient.

The foregoing should not be given to infants under eight months of age. Or:

℞.	Ext. belladonnæ flu	m. iv		25
	Potass. bromidi	gr. xlviii	3	20
	Glycerini	℥iii	90	
	Aquæ dest. q. s. ad	℥iv	120	

M. Fiat mistura. Sig.: Two teaspoonfuls every four hours.

Medicolegal.

Power of School Board to Require Vaccination.—The Supreme Court of North Carolina says that the sole question presented in the case of Hutchins vs. School Committee of Town of Durham was whether the following resolution was a reasonable exercise of the powers of the school committee of the city of Durham: "Whereas, From the report and recommendation of Dr. N. M. Johnson, superintendent of health of Durham County, in the judgment of this committee, general vaccination of teachers and children attending the schools is desired and required for the public safety: Now, therefore, be it resolved, that no teacher or pupil be allowed to attend any school of the city of Durham after April 1, 1904, who does not present to the principal of such school a certificate of a physician of the city showing that such teacher or pupil has been successfully vaccinated within three years from that time, unless such person has been vaccinated within ten days preceding the date he or she presents himself or herself for such attendance, and this resolution shall be a permanent regulation of the schools." An epidemic of smallpox prevailed in the city of Durham and its suburbs last spring, not less than 1,000 persons being attacked, and the above resolution was passed as a protection to the 2,500 children in the schools of that city, the attendance in which had fallen off 40 per cent. by reason of the fear of contagion. These facts were averred in the answer and found to be true by the judge. In the judgment of the Supreme Court, the resolution was a proper and reasonable exercise of the powers of the defendant. This, the court says, was not a question of compulsory vaccination under legislative authority, but simply whether, if a child was not vaccinated, the school board could, as a precautionary measure, exclude all such from the school, by a resolution, under the power given in the charter to "have entire and exclusive control of the public school interest and property in the town of Durham, prescribe rules and regulations . . . and do all other acts that may be just and lawful to conduct and manage the public school interests in said town." The plaintiff relied on Potts vs. Breen, 167 Ill. 67, that, in the absence of express legislative power, a resolution requiring vaccination as a prerequisite to attending schools is unreasonable, when smallpox does not exist in the community, and there is no reasonable ground to apprehend its appearance. But this court is not inclined to follow that authority. With the present rapid means of intercommunication, the court says, smallpox may make its appearance in any community at any moment without any notice given beforehand, and incalculable havoc be made, especially among the school children, which can not be remedied by a subsequent order excluding the non-vaccinated. "An ounce of prevention is worth a pound of cure." Besides, that case was not in point here, where smallpox had been epidemic, and was still threatening. The language of the resolution making it "permanent" would not prevent its repeal if on the subsidence of the danger the school board of that day should deem it proper to repeal. If the action of the board was not satisfactory to the public a new board would be elected who would rescind the resolution. The fact that it would be dangerous to vaccinate the plaintiff's daughter, owing to her physical condition, would be a defense for her to an order for general compulsory vaccination, but was no reason why she should be excepted from a resolution excluding from the school all children who had not been vaccinated. That she could not safely be vaccinated might make it preferable that she herself should run the risk of taking the smallpox, but was no reason that the children of the public school should be exposed to like risk of infection, through her, or others in like case. Though the school children were vaccinated, there were always some whose vaccination was imperfect and danger to them should not be increased by admitting those not vaccinated at all. Besides, a rule not enforced to all alike would soon cease to be a rule enforceable at all.

Construction of Practice Act and What Violates It.—The Supreme Court of Iowa says, in State vs. Heath, that certain penalties are denounced by section 2580 of the Code against those who shall practice medicine, surgery or obstetrics in that state without first having obtained and filed for record the certificate required by the chapter of which that section forms a part. Section 2579 defines who shall be deemed to be practicing medicine as follows: "Any person shall be held as practicing medicine, surgery or obstetrics, or to be a physician, within the meaning of the chapter, who shall publicly profess to be a physician, surgeon or obstetrician, and assume the duties, or who shall make a practice of prescribing or of prescribing and furnishing medicine for the sick, or who shall publicly profess to cure or heal." The manifest intention of the legislature was to divide those who shall be deemed practicing medicine into three classes: 1, all "who shall profess to be a physician, surgeon or obstetrician and assume the duties;" 2, those "who shall make a practice of prescribing or prescribing and furnishing medicine for the sick," and 3, those "who shall publicly profess to cure or heal." It is doubtless true that a mere public profession of an ability to heal would not subject any one to the penalties of the law. Such profession must be made under such circumstances as to indicate that it is made with a view of undertaking to cure the afflicted. One publicly professes, in announcing to the public generally his claim of skill in the art of healing, and is guilty, under section 2580 of the Code, if, without a certificate, and not within the statutory exceptions, this is done with the purpose of treating the maladies of patients who may engage his attention. There is some reason for not exacting proof of actual treatment in all cases. Should one profess to be a physician, and assume the duties or prescribe for the sick, little difficulty might be experienced in obtaining evidence of the fact. But suppose a charlatan, quack or other persons assumes or pretends to believe he may effect cures in an invisible manner, and undertakes to do so? Proof of his effort would be all but impossible. The statute, in order to be effective, has denounced the public profession that he will cure or heal, and this may be proven without exacting evidence that he has actually undertaken to do so. The statute, when fairly construed, does not seem capable of a broader construction. Nor does the court deem this essential in order to sustain its constitutionality. The statutes do not attempt to discriminate between different schools of medicine or systems for the cure of disease. No method of attempting to heal the sick, however occult, is prohibited. All that the law exacts is that, whatever the system, the practitioner shall be possessed of a certificate from the State Board of Medical Examiners, and shall exercise such reasonable skill and care as are usually possessed by practitioners in good standing of that system in the vicinity where they practice. This excludes no one from the profession, but requires all to attain reasonable proficiency in certain subjects essential to the appreciation of physical conditions to be affected by treatment. The object is not to make any particular mode of effecting a cure unlawful, but simply to protect the community from the evils of empiricism. Often the individual alone suffers from the want of proper attention, but in cases of contagious or infectious diseases the entire community may be endangered. In no profession, occupation or calling are the people more easily or readily imposed on. Section 2576 of the Code requires all, regardless of the particular school, to be examined in anatomy, physiology, general chemistry, pathology, surgery and obstetrics. Surely it is not unreasonable to exact for every one who proposes to undertake to prevent, cure or alleviate disease and pain some knowledge of the nature of disease, its origin, its anatomical and physiologic features, its causative relations and of the preparation and action of drugs. At any rate, the state, in order to guard the people against the effects of imposition or ignorance, had the right to exact such knowledge. The examination in materia medica, therapeutics and the principles and practice of medicine must correspond to the school according to which the applicant proposes to practice. In this case it conclusively appeared that the accused, who had never obtained a certificate from the State Board of Medical Examiners, professed publicly to heal a great variety of ailments (by "magnetic treatments"), and so did for the purpose of procuring patients and treating them. The question of his guilt should have been submitted to the jury.

1. **Roentgen Rays in Leukemia.**—Dock says that some cases of leukemia undergo marked change for the better under treatment with the Roentgen rays. The leucocytes fall to normal and sometimes show no more pathologic cells; the red

corpuscles improve, the enlarged spleen and lymph glands resume normal proportions, the general health seems restored. In some cases the effects are imperfect. In no case has observation been carried out long enough to speak of cure. In several cases death occurred while the symptoms seemed to indicate improvement. The action of the rays probably consists in affecting the tissues that produce the pathologic leucocytes, either directly or more probably through the production or setting free of substances that affect cell formation, or degeneration, or chemotaxis, or all of these processes. Further investigation is necessary. At present the improvement must be considered functional and not affecting the original cause, nor in a permanent way the morbid histology of the disease. The improvement of the red cells may be due to general stimulation of nutrition, in which suggestion may have a part, or by diminution of lymphoid or myeloid tissue. Roentgen ray treatment of leukemia is dangerous on account of the usual risk of dermatitis and burns, but probably also on account of toxic processes as yet impossible to explain. No stronger claims can be made for it than can be made for arsenic and certain serums and bacterial toxic substances, but it may prove more certain in its action than arsenic, and it can be more readily applied in practice than the injection methods. Great care should be taken to avoid burns. Methods should be as fully described as possible in each case; the blood should be carefully examined as fully and as frequently as possible and, if possible, urine examinations should be made to throw additional light on metabolic changes.

4. **Prevention of Measles and Whooping Cough.**—Cacerly deprecates the tendency on the part of the profession and of the public to view these diseases as harmless. Although the death rate from scarlet fever has been lessened considerably by judicious preventive measures, that from measles and whooping cough remains unchanged, these diseases causing more deaths than scarlet fever. From their fatalities they are as important as scarlet fever, or diphtheria, or even smallpox. Their prevention presents peculiar difficulties. First, the indifference of the public, shared by the profession. Second, the failure of many patients to see a physician. Third, their contagiousness at a time when they can not be recognized, and fourth, the variable length of time that they remain virulent. There is not sufficient unanimity among doctors as to the necessity of preventing these diseases. They are difficult of early and certain diagnosis because their early symptoms are common to these and many other less severe and less contagious diseases. The schools offer the best opportunity for their spread. In catarrhal diseases of all kinds affecting the upper air tracts, the child should be excluded from the school. The early communicability of measles and whooping cough should never be overlooked.

6. **Unusual Case of Addison's Disease.**—The striking features of Whitney's case were an entire lack of the usual pigmentation of the skin, and a course which was extremely acute, that is, so far as the clinical manifestations are concerned, since the adrenal tuberculosis was undoubtedly chronic and of very slow development. The diagnosis was not made until at the autopsy.

13 *The Significance of Pus in the Nose, with Special Reference to the Affections of the Accessary Sinuses and Their Proper Treatment. George L. Richards, Fall River, Mass.

12. **Strangulated Hernia Treated by Operation.**—Vaughan analyzes 25 cases of strangulated hernia, including only those cases in which the intestine was not only incarcerated, but the circulation of blood so obstructed as seriously to threaten and in several cases to destroy the integrity of the intestine. Five were femoral, and 20 were oblique inguinal hernias. Twenty-three were on the right side, 2 on the left. There were 2 cases of pro-peritoneal or interstitial hernia. Only one case was complicated with an undescended testicle. The youngest patient was six weeks, and the oldest 77 year old. In 8 cases the point of greatest restriction was at the external ring, in 7 cases at the internal ring, and in 1 case in the abdominal cavity (constriction not determined in 9 cases). In 19 cases the sac contained small intestine, and in every instance in which the portion could be identified—11 in number—it was found to be ileum. In 1 case, the contents were two loops of small intestine; in 1, small intestine and omentum; in 1, large and small intestine and omentum; in 1, large intestine (sigmoid flexure); and in 2, omentum only. In 11 cases, dark or turbid fluid—sometimes blood clots—were found, and in these cases strangulation had existed from 2 to 96 hours; in 8 cases over 6 hours, and in 3 cases less than 6 hours. Venous thrombosis in the mesentery, ecchymosis, or hematoma of the intestinal wall or mesentery were found in 10 cases. In 2 cases the intestinal wall was rough and bruised, and in 1 a large hematoma was found in the intestinal wall and was treated by incision, evacuation and suture. In 9 cases the contents of the sac were gangrenous, 3 of the omentum only, and 6 of the intestine, and in 4 of these there was what is usually called general peritonitis. Besides the physical signs, the two most valuable symptoms were pain and vomiting. Pain existed in all the cases, but varied in character, duration and locality. Vomiting occurred in 20 cases, nausea without vomiting in 2, and neither nausea nor vomiting in 3. In 4 cases the so-called stercoraceous vomiting occurred. In all the cases except 3, after attending to the contents of the hernial sac, some operation for radical cure was performed. Of the 3 cases mentioned, 2 were cases of peritonitis, in which it was thought best to provide for drainage, and the third did not survive the operation. The formation of an artificial anus with or without resection of the intestine must not, says Vaughan, be done in any case in which the patient's condition will permit resection with immediate reunion. In every case in which the patient's condition will permit an operation, the radical cure should be performed. There were 6 deaths in Vaughan's series. One patient was a hard drinker; one, a woman, aged 77 years, who had suffered from strangulated hernia 13 days and had an incipient general peritonitis when the gangrenous intestine was resected. She died of peritonitis 48 hours after operation. The third case was that of a patient who had been suffering with intestinal obstruction nine days and who was very weak. He died on the table, apparently from exhaustion. The fourth case was one of strangulated hernia of nine days' standing, with general peritonitis, death occurring 14 days after the operation. The fifth case was a man, aged 60 years, who had gangrene of the intestine with numerous mesenteric thrombi and beginning general peritonitis. The last case was a feeble man, aged 77 years, inmate of an insane asylum, who had had strangulation of a right oblique inguinal hernia for 8 hours, and had been treated by taxis. Death occurred on the fourth day from toxemia or exhaustion. No peritonitis. This gives a mortality of 24 per cent. Cases in which the contents of the sac were in good condition, 16; 3 deaths; mortality, 18.75 per cent. Cases in which the contents of the sac were gangrenous or general peritonitis existed at the time of operation, 9; deaths, 3; mortality, 33.3 per cent.

13. **Significance of Pus in the Nose.**—A patient presenting himself with pus coming from one or both sides of the nose, the first thing to do, says Richards, is to clear the nose of all visible sources of obstruction, especially polypi; examine the teeth, to see whether there is anything in the way of probable dental origin of sinus trouble. Then at-

tempt to ascertain whether the pus comes from the antrum or from the frontal sinus or from the ethmoidal cells. Transillumination and exploratory puncture of the antrum may be resorted to. If the antrum is free, explore the frontal sinus; try to wash out with the canula or pass a probe, if possible; if not, remove the middle turbinate. If the antrum contains pus, irrigate. If these measures fail, a radical operation must be done. The better the drainage, the faster the cure, and to accomplish this it is necessary to have a good-sized opening into the antrum. If the pus appears to come from the frontal sinus, wash out with a canula, if possible, pursuing this treatment a reasonable length of time, and being guided as to the question of a future operation somewhat by the feelings of the patient, somewhat by the annoyance of the discharge, somewhat by the chronicity of the case. It is to be remembered that the frontal sinus is a simple, large, irregular cavity, which may communicate with one or more of the anterior ethmoidal cells, and that the operation, while not of itself especially serious, may mean a more or less prolonged course of after-treatment. Where there are several empyemas, it is better to clear out the nose as thoroughly as possible, and then, under ether, do the operation on all the cavities at once.

15. The Plasmeba of Dengue.—This name has been given to a parasite found by Eberle in the blood of persons suffering from dengue. The parasite of dengue belongs to the class sporozoa, and since it is found first in the plasma of the blood, Eberle has given it the generic name plasmeba. This plasmeba, primarily found in the blood plasma, impregnates the corpuscles, producing a pale, violet tinted growth assuming various shapes as it increases in size, and in which can be noticed, after from two to four hours, faintly darker bodies, the earliest spore formations which occupy usually from two-thirds of to the entire corpuscle. On many occasions, when the spores form in the pseudopodiæ, they give the corpuscles the appearance of being crenated, but in fact they are merely projections beyond the border of the corpuscle pushing out the elastic limiting membrane of the cell. These spores mature in the course of a few hours and are characterized by a definite outline enclosing a pale protoplasm without nucleus or nucleolus. These matured spores are highly refractive and finally burst through the limiting membrane of the corpuscle and are poured out into the plasma (the greater number, however, being passive) and are ready to enter on the new cycle. The dengue plasmeba is smaller and much more active than the ameba in malarial blood. Its detection requires great patience on the part of the investigator and thorough knowledge of its morphology. The secondary changes in the corpuscles are unlike those of any of the malarial types. Crescents or flagellæ have not been noticed. There is no enlargement of the spleen or liver. The plasmeba can be found in fresh blood specimens during every day of the disease, and in the same specimens sporulation and segmentation go on continuously. Quinin has no effect in cutting short the disease, nor in lowering the temperature. Only in complicated cases would its administration be recommended, and then it should be combined with other antipyretics. The minute dengue organisms stain beautifully in weak eosin solutions and in methylene blue.

16. Removal of Internal Hemorrhoids by Excision.—LaPlace describes his method as follows: The patient, prepared as usual, is placed on the left side with the thighs flexed on the abdomen. The sphincter ani is dilated by stretching with both thumbs. The hemorrhoidal area is brought into view by clamping with forceps (preferably Kocher's) each hemorrhoid at its upper and lower extremity parallel with the course of the rectum. The upper forceps being held in the left hand, the hemorrhoid is cut immediately above the forceps, with curved scissors, just enough to allow the cut to be closed by the immediate insertion of a continuous suture of No. 2 cumolized plain catgut, on a medium-sized curved Hagedorn's needle. This first cut being closed, the hemorrhoid is again cut a little, and the wound is closed by the same continuous stitch, and so the procedure is repeated until the hemorrhoid is removed, when the suture is finally tied. Should any hemorrhage occur, a whipped suture is applied locally. The result is a linear cut securely sutured. The danger from hemorrhage or from sepsis is reduced to a minimum. The catgut drops away in due time. Pain is rarely present and occurs only when the sutures have been applied too deeply. The advantages of the method are precision, absence of hemorrhage during or after the operation, safety, and simplicity. LaPlace has performed it 83 times without any complication in any case. The patients are cautioned to keep the bowels locked, with a half-grain opium pill twice a day, for two days. On the sixth day an enema is given and the patient is ready, as a rule, to be discharged. No dressing is applied, except a pad externally.

25 Paraphimosis in a Young Girl. M. I. Beeman, Newburgh, Ont.

21. Antitoxin Treatment of Tertian Malaria.—The antitoxin used by Ford was obtained from rabbits which were injected with the blood of patients suffering from malaria, or infected mosquitoes were allowed to bite them. The material injected was either the fluid serum or defibrinated serum, or serum, or corpuscles desiccated at a temperature below 53 degrees C. Of 9 patients treated, 2 were apparently unaffected; in 1 there was a temporary disappearance of symptoms, in 1 an abscess developed at the site of injection. Four patients recovered. The fever and parasites disappeared in the fifth case, but the course of the disease so much resembled a case of spontaneous cure that Ford regards it as inconclusive, in spite of the severity of the infection and the promptness with which the parasites disappeared from the blood after the injection of the serum.

23. X-Rays in Primary Lupus of Oropharynx.—Birkett's patient, a boy, aged 15, with a family history of tuberculosis, had two distinct growths in the oropharynx, each situated on the lateral and partly on the posterior walls of the pharynx. The growths were distinctly nodular in appearance, about the size of a swollen sago-grain, quite separate and distinct in the central portion, but merging into one another at the periphery; pale pink in the center, darker toward the periphery. The structures anterior to the growth were not involved. The uvula on its palatal surface seemed normal. The infiltrations extended upward to the cushion of each Eustachian tube, and from there towards the center of the nasopharynx along its root. There was no extension into the posterior nares. The pharyngeal aspect of the uvula showed two nodules, each about the size of a lentil. Under ether, by means of cutting forceps, Birkett removed the greater portion of the masses involving the lateral walls of the oropharynx. The microscope showed tubercle bacilli in typical tubercular tissue. Animal inoculation was positive. The local treatment carried out subsequent to the removal of the masses consisted of curetting the infiltrated areas and subsequently rubbing in a mixture of lactic acid and glycerin. This treatment proving ineffectual, the galvanocautery was tried, and finally, the Roentgen ray. The patient was treated with a regulating tube with a vacuum equal to a three-inch spark-gap, which was supplied from an eighteen-inch coil, operated by an electrolytic interrupter. The tube was placed ten inches from the patient and ten-minute exposures were made for ten treatments. On account of inflammation, treatment was suspended for three weeks. Daily treatments were then given for 23 days, the face being protected by a piece of wood painted with 11 coats of white lead on each side. A recurrence was treated in the same manner and the results at the present time are most satisfactory.

28. Hour-Glass Deformity of Stomach.—Scudder's patient, a woman, aged 38, suffered from influenza 10 years ago, and since that time she has had more or less trouble with her stomach, complaining of dyspepsia and indigestion. She was unable to keep anything on her stomach and was nourished by nutrient enemas. On percussion the lesser curvature of the stomach was found two inches above the umbilicus and the greater curvature three inches below. An operation was undertaken because of the persistent vomiting, and the evident obstruction. On opening the abdomen, an hour-glass deformity of the stomach was found. The obstructing portions were evidently cicatrices of old and recent ulcers. A gastrogastrostomy and a gastroduodenostomy were done. Both of these operations were facilitated by the use of rubber-covered clamps, which prevented hemorrhage and the escape of stomach or intestinal contents. The patient made an uninterrupted recovery, being able to take with relish whatever food was given her.

29. Decrease in Consumption Death Rate.—Miller has reviewed such literature on the subject of tuberculosis as deals with the work done for its extinction. Treatment of any

35. Etiology of Carcinoma.—Orth says that it is a matter of no consequence etiologically in proving the transplantability of cancer, to produce a secondary cancer even on another individual, but it is of consequence to produce a primary tumor. As long as that is not successfully accomplished, and that by means of an organism in pure culture, so long is also the parasitic nature of cancer not proved.

38. Operative Treatment of Mammary Cancer.—Warren has collected a series of 100 consecutive cases of mammary cancer taken from his hospital and private practice, in which at least three years had elapsed from the time of operation. These cases have all stood the test of careful microscopic examination, and their subsequent history has been followed up carefully, thus enabling him to give end results bearing on all important points. These cases represent the average, such as the surgeon would consent to operate on with hope of benefit, if not of cure, to the patient. The results illustrate what may be accomplished under the usual conditions of surgical practice. Recognizing the importance of early surgical interference, Warren makes it a practice in all cases of tumor of the breast, in which there is uncertainty as to the nature of the growth, to explore the gland through the so-called Thomas incision, and thus arrive at the earliest possible diagnosis. In five cases it was evident that cancer had developed as a secondary process in either a cyst wall or in that chronic inflammatory condition of the gland tissue which is the accompaniment of cystic degeneration. All but one of these cases are reported as cures. In another case cancer was found growing in a small fibroma which had existed for over twenty years. Warren considers this strong testimony in favor of early operation of non-malignant tumors of the breast. In six cases there was a history of abscess; in 16 some kind of blow; in 18 cases there was a family history of cancer. The disease was most commonly observed in the sixth decade of life, 36 cases occurring between 50 and 60, 14 cases between 30 and 40, 28 cases between 40 and 50; 15 cases between 60 and 70, 5 cases between 70 and 80. The average age of those cured by operation was 52.9 years; the youngest was 31 years old, and the oldest 73. A pathologist was present at each operation and a provisional diagnosis made by the microscope at the time, also of the condition of the lymph glands removed, the dissection being continued until the last gland removed was reported not infected. Of the 100 cases 26 can be regarded as cured, that is, the patients are either alive (free from recurrence) or have died from other causes three years or more after operation. Seven of the 26 cases died, the cause and time of death being as follows: Apoplexy, 10 years after operation; cholera, 6 years; pulmonary hemorrhage, 14 years; grippe, 13 years; pneumonia, 10 years; apoplexy, 8 years, and pneumonia, 4 years after operation. Of the remaining 19 cases one each is alive at 20, 19, 18, 14, 11, 10, 4 and 3 years after operation;

two each 10 and 8 years, three 7 years, and five 5 years after operation. The percentage of cures in each variety of cancer is as follows: Colloid, 2 cases; cured, 2; 100 per cent. Cancer, 26 cases; cured, 6; 23 per cent. Scirrhus, 28 cases; cured, 12; 42 per cent. Medullary, 40 cases; cured, 3; 7 per cent. Paget's disease, 1 case; cured, 1; 100 per cent. Adenocarcinoma, 3 cases; cured, 2; 66 per cent. Warren divides the clinical course of his cases into stages. The first stage includes all cases in which the disease still remains practically in the condition in which it was when first discovered by the patient. The second stage marks the beginning of the period of visible activity in the growth. In the third stage are included all cases which have advanced beyond the immediate neighborhood of the primary focus, and have involved adjacent regions, either by direct extension or by metastases. The summary of cases made on this basis is as follows: First stage, 45 cases; cured, 19; 42 per cent. Second stage, 35 cases; cured, 6; 17 per cent. Third stage, 18 cases; cured, 1; 5 per cent. In 2 cases death resulted from the operation, and, therefore, these are not included in this list. Of 23 cases in which the skin was adherent to the growth, 6 died within a year after operaton, 5 within two years, 1 within three years, 1 five and a half years after operation. Two recurrences, four years after operation, are alive and well, and there are four cures, 13, 10, 6 and 4 years after operation. Adhesion of the skin diminishes the chances of cure by one-third. In 72 cases enlarged glands were felt in the axilla, no axillary involvement in 17, no record in 11. Of the 17 cases 11 are cures, 64 per cent. Among the 26 recorded cures 12 cases had enlarged axillary veins, no glands in 11, no record in 3. Of the 72 cases in which enlarged glands were present there were 8 in which glands were also felt above the clavicle. One of these cases died at the operation. Six that died with recurrence had lived on an average, 1.8 months after operation. One is living with recent recurrence 8 years after operation. In 61 cases in which death occurred from recurrence, the average duration of life after operation was 2 years and 1 month. In 52 cases recurrence took place on an average 1 year and 10 months after operation. Of the 61 cases 12, or 19 per cent., died after the three-year limit. After a period of 5 years the percentage is as low as 8, and it is not until 9 years have elapsed that no deaths occurred. Of 9 living cases in which there is a history of recurrence, 2 that are cured have gone respectively 16 and 10 years since the last operation. In 14 cases the disease had advanced so far that a radical cure could not be expected, yet one lived 2 years, three lived 3 years and one died 8 years after operation. The situation of the disease was as follows: Upper outer quadrant, 17; center of breast, 12; upper hemisphere, 10; lower outer quadrant, 8; upper inner quadrant, 7; whole breast, 7; outer hemisphere, 7; lower hemisphere, 3; lower inner quadrant, 1; inner hemisphere, 1; axillary border, 1. The average duration of the disease in the 100 cases was 11.8 months before treatment, but the average duration in the 26 cured cases was 12.3 months. Retraction of the nipple was recorded in 22 cases. The operation performed in the first 50 cases consisted in a removal of the breast and of the pectoral fascia and a dissection of the axilla. In the second 50 the "completed" operation was performed, both pectoral muscles being removed, the clavicular portion of the pectoralis major being left behind and the posterior cervical triangle frequently dissected. The results of operation in the two series of 50 cases show a slightly greater number of cures where the lesser operation has been performed. In the first 50 there were 14 cures and in the second 50 only 12. In the series of 100 cases there were 2 deaths from the operation, 1 from acute septic infection, due apparently to the fact that the patient was put in a bed previously occupied by a case of erysipelas, and the second case was one of pulmonary embolism caused by allowing the patient to sit up too soon and to move about too freely after operation. Speaking of cancerous infection during the operation, Warren says that it is his habit to act on the supposition that such danger exists, and throughout the operation to attempt to keep the parts exposed protected as much as possible by gauze packing. His modification of the Halsted operation has the advantage that nine-tenths of the wound is not exposed, nor, in fact, touched by an instrument until the close of the operation, presenting, therefore, much less danger of cancerous infection. In exploratory incisions instruments should be changed and the wound leading to the disease temporarily closed by suture or packed with gauze, so as to protect the operation wound as thoroughly as is possible.

40. **New Method of Closing Wounds of Large Arteries.**—Brewer records experiments undertaken with a view of obtaining some new and simple method of closing accidental wounds of the larger arteries. Experiments were carried out as follows: As soon as the artery is exposed it is brought to the surface of the wound and incised with the point of the scalpel. The vessel is then compressed above and below the wound to prevent excessive hemorrhage, and the sheath carefully removed. The artery is next cleansed of all blood by the use of a small pledget of gauze moistened with ether. As the ether evaporates the vessel wall is left clean and dry. A small strip of a specially prepared plaster sterilized by formaldehyd vapor is next passed beneath the vessel, and the two corners held by two small artery forceps. The strip is then put gently on the stretch and the lower extremity of the strip held by clamps placed firmly in contact with the vessel, while the upper extremity of the plaster is slowly drawn upward. This causes the vessel to rotate with the plaster until the horizontal edge of the lower extremity of the plaster is on a level with the vessel and firmly adherent to it. The two clamps are then passed over the vessel and the plaster kept on the stretch while the operator, with thumb and forefinger, gently rotates the vessel backward, and at the same time compresses the enveloping plaster until it adheres snugly. The redundant plaster is then removed and the vessel allowed to fall back to its normal position in the wound. The wound is closed without drainage and the gauze and collodion dressing applied. Brewer is of the opinion that, in dogs at least, small wounds of the larger arteries can be successfully treated by the application of an aseptic elastic plaster. This plaster should be exceedingly thin, very adhesive and applied with the minimum of pressure on the vessel wall; and that, if the operation is carried out with perfect aseptic technic, the plaster becomes embedded in the tissues and produces no outward symptoms. Brewer says he would not hesitate to use this method on the human subject if an occasion presented.

43. **Celiac Parotitis.**—Among many complications, says Dyball, which may be met with after operations on, or diseases of, the abdominal and pelvic viscera, one of the rarest is parotitis. To this form of parotitis Dyball proposes to give the name celiac parotitis. He concludes that it is most probable that celiac parotitis is due to the action on parotic glands of toxic substances absorbed into the blood and derived from (a) the secretions of certain organs modified by injury or disease; (b) toxins of microbic origin (*Bacillus coli communis*) absorbed either from the alimentary canal, peritoneal cavity or bladder; (c) products of deranged digestion. In any given case of injury or of disease of the abdominal or pelvic viscera, the occurrence or not, of parotitis will, therefore, depend on the presence and on the absorption in sufficient quantity of some of these various toxic agents. Suppuration does not appear to be an esential feature of the condition, but is due to the fact that the parotid gland, when inflamed by the action of these toxic agents, forms a *locus minoris resistentiæ* and becomes secondarily infected by pyogenic organisms reaching it (a) by the blood stream; (b) by Stenson's duct. Dyball suggests this theory as one which affords an explanation of all cases, and which is in accordance with present knowledge of the colony.

44. **Duodenal Ulcer.**—Mayo reports 59 operations in 58 cases; 7 for acute conditions developing with one exception, on chronic ulcer, with 3 deaths. Fifty-one operations for chronic conditions gave one death. He says that at the present time posterior gastroenterostomy appears to be the operation of choice in the chronic cases.

50. **Undescended Testicle.**—Odiorne and Simmons performed orchidopexy 7 times in children ranging in age from 5 to 13

years. In but two instances was a perfect result obtained, and this in the same patient, aged 13, who had double retention. Both testicles are normal in size, position, and probably in functionating power. Two other boys were operated on at the same age, 13, and in both the testicles have remained in the scrotum. Although they have retracted to a position high in the scrotum, they are not in contact with the pubic bone. Neither testicle is notably atrophied. One of the patients suffers some pain. One case, aged 11, has a poor result, the testicle being much atrophied and fixed firmly just outside the ring, where it is a constant source of pain, and would better be removed. Two children were 5 years old at operation. In one the testicle drew up into the canal, where it remains very small and undeveloped; in the other it retracted to the pubic region, where it has as yet given no trouble. The only really satisfactory results were in the 4 cases, aged 13. As a result of 11 operations performed on adults of from 16 to 42 years of age, 5 testicles have remained in the scrotum, 4 of them occupying a high position in it, while the remaining one is in almost perfect position and fully one-half normal size, yet is the seat of frequent inflammatory attacks due to injury. Three testicles retracted soon after operation into the canals, where they remained very much atrophied. One of them is the cause of much pain. Two have retracted to the pubic region, where they are the source of considerable annoyance, undoubtedly due to their position. One of these is atrophied. In every case in which the organ appeared normal at the time of operation there has been a subsequent diminution in size. In two cases, however, the atrophy is not very marked, the testicle being fully one-half normal size. In 2 cases symptoms were distinctly relieved, in 3 not relieved and in 2 others were aggravated. In no case has there been a recurrence of a complicating hernia.

53 *Preliminary Report of Results Obtained with Extravisceral Ligature in Enteroenterostomy and in Gastroenterostomy. R. C. Coffey, Portland, Ore.
54 Heart Failure Due to Acute Indigestion. L. R. Markley, Bellingham, Wash.

52. **Chorea in Pregnancy.**—Semple says that the perils of chorea in pregnancy are so great that when the symptoms increase, in spite of medical and moral treatment, and the sleep is becoming disturbed, the only course left for the physician is to induce premature labor, which gives the patient the only chance of recovery.

53. **Extravisceral Ligature.**—After having performed an enteroenterostomy and a gastroenterostomy, Coffey suggests the picking up of the side of each intestine entering into the anastomosis and tying it with a strong silk or linen thread, including as much of the intestine as necessary to make a hole of the desired size. Then take a Lembert suture and sew the intestines together, surrounding the two portions of intestine entirely with the suture. This method is a modification of that of McGraw, and is the result of a suggestion made by Weir that an opening between two hollow viscera would be better and more permanent, if it could be made in the form of a hole, like that punched through leather in harness-making, than the simple slit made by the McGraw ligature.

58 Gc [illegible] Huber, New York.
59 *Ca [illegible] Simulating Acute Scarlatinal [illegible] hington, D. C.

55. **Recurrent Vomiting.**—Rachford's treatment of the prodromal stage is as follows: One-quarter of a grain of calomel and 5 grains bicarbonate of soda are given every half-hour until 2 grains of calomel are taken. If the stomach is not too irritable the calomel should be followed, in two or three hours, by a saline laxative, and four or five hours later by benzoate of soda in from 3 to 8 grain doses every two or three hours, dissolved in essence of pepsin and peppermint water. No food whatever should be given. Water may be allowed if the stomach will retain it. The curative treatment consists of the carrying out of proper hygienic measures and a carefully restricted and selected diet. Sources of reflex irritation should be sought for and, if possible, removed. In the medicinal treatment Rachford considers the wintergreen salicylate of soda and the benzoate of soda most valuable remedies, and describes them in the following combination:

℞. Sodii salicylatis (gaultheria)..............ʒi 4
Sodii benzoatis ....ʒii 8
Pepsin essence ....fʒii 60
Aquæ menth. pip.........................fʒii 60
M. S.: Teaspoonful after meals for a child 6 years of age.

In the more severe cases this prescription must be continued for months at a time and, after this, is to be given once a day for an indefinite period.

56. **Pyloric Stenosis in Infancy.**—Shaw and Elting attempt to show that pyloric stenosis in the infant is of much more frequent occurrence than is commonly supposed, and that medical treatment of these cases is both uncertain and unsatisfactory. They advise early surgical interference, before the strength and vitality of the patient have become seriously reduced, either pyloroplasty or anterior gastroenterostomy being the operations of choice.

59. **Carbolic Acid Poisoning Simulating Acute Scarlatinal Nephritis.**—Adams' case, a girl, aged 10 years, had a moderately severe attack of scarlet fever without any troublesome symptoms. It was impossible from beginning to end even to approximate the quantity of urine passed in any twenty-four hours, as the mother invariably had an excuse for not keeping it or not measuring it. At the time of the seventh visit the child complained of intense itching. The mother was instructed to bathe her twice daily with a teaspoonful of carbolic acid to the quart of water (1 to 256). The itching was allayed and there was neither tingling nor irritation of the skin from the carbolic acid. Thirteen days later the patient passed a fair quantity of dark urine which was found to contain carbolic acid. The eyes were only slightly puffed; otherwise the girl was in fine condition. Adams is satisfied that the nephritic symptoms which appeared were due to the irritation of the drug and not to the toxemic effect of the scarlatina. This opinion was confirmed by the speedy relief of the kidney irritation with the elimination of the carbolic acid.

3. Vomiting of Pregnancy.—Martin offers the following classification of this condition, and in doing so cautions that there may be vomiting due to phthisis or gastric ulcer coincident with pregnancy. 1. Where the nausea or sickness is light, with, at the most, retching, occurring usually in the forenoon and passing away just before or when quickening takes place, without producing any constitutional disturbance. 2. Where vomiting as well as nausea is of frequent occurrence, not confined to any period of the day, and resulting in appreciable failure of health and emaciation. 3. Where vomiting is so constant and persistent that all food is rejected, rapid emaciation follows, with febrile disturbance, circulatory troubles, jaundice, dry tongue, quick pulse, delirium and threatened death. 4. Where organic disease is present, and it is difficult or impossible to say what share pregnancy has, in producing a dangerous or fatal result An extended clinical experience leads Martin to say that there is simple nausea with or without actual emesis, of physiologic and of reflex origin, a symptom only due to hyperemia, the developing uterus, vessels and nerves in a confined cavity. That malposition of the uterus, if the cause of so many troubles in ordinary conditions of health, must be a graver trouble in the pregnant woman, and thus increases the vomiting of pregnancy and consequent malnutrition and emaciation. That in the absence of uterine troubles and organic disease hysteria plays an important rôle and usually defies all therapeutic remedies If operation should be deemed necessary it should be carried out under thoroughly antiseptic conditions and anesthesia. Martin has found nepenthe by mouth and morphin by rectum most useful in the treatment of vomiting of pregnancy. The induction of abortion must be considered in those cases which come under the third and fourth divisions of his classification The responsibility of such an operation should be a divided one, and the patient should have the benefit of it before it is too late, not waiting too long under the hope that vomiting may suddenly subside, as it sometimes does Better attention to health and the greater inclination to athletic exercises and hygienic surroundings may have a tendency to counteract the artificial existence which has for so many years existed in the child bearing population.

5 Indications for Operation in Stomach Disease.—Saundby urges the importance of the assistance to be derived from surgery in the treatment of stomach diseases, the need for seeking surgical aid before the patient's strength is undermined by the duration of the disease, and the value of simple means of diagnosis. Surgeons should reconsider the claim to operate in every chronic ailment of the stomach which has not been relieved by medical means, to select their cases by studying the indications which justify operative interference, and to avoid, so far as possible, operating on patients who are the subjects of general neurasthenia.

7. **Treatment of Duodenal Ulcer.**—Power attempts to show that duodenal ulcers are not very uncommon; that usually they are single, and more frequent in men than in women. These ulcers may perforate and cause acute symptoms, or they may heal, and by cicatrization lead to symptoms of chronic duodenal obstruction. Power says the sequelæ of a healed ulcer may be so remote that the symptoms are mistaken for those due to cancer of the pylorus, and the patient is allowed to drift from bad to worse under the erroneous notion of the day that he is bound to die. In many cases there is no means of recognizing the existence of the ulcer until it perforates or until the results of its cicatrization become manifest. The treatment of duodenal ulceration laid down by Power is as follows: 1. Direct suture of a perforated ulcer, the prognosis being less favorable than in similar cases of perforation. 2. The performance of gastrojejunostomy in cases of dilated stomach due to duodenal constriction, the prognosis being the most favorable of all the conditions for which this operation is performed at the present time.

11. **Abdominal Pregnancy.**—In this paper Bland-Sutton brings forward facts in support of his contention that primary abdominal pregnancy is still an unverified speculation.

13. **Unusual Effects of Movable Kidney.**—In one case cited by Moullin a movable right kidney gave rise to a series of symptoms resembling very closely those ordinarily present in chronic gastric ulcer. The pain invariably came on from a quarter to half an hour after meals. Solid food made it worse, vomiting was frequent, and was rather encouraged as it relieved the pain. The stomach was not dilated or displaced. There was a little tenderness on deep pressure to the right of the epigastrium, but no tumor could be felt. Both kidneys were movable, the right one in particular, descending so far when the patient strained or coughed that it came quite below the thorax and the hands could be made to meet above it. In two other cases there had been repeated attacks of colic beginning in the right hypochondrium and resembling mild attacks of biliary colic, but bearing little or no relation to food. They rarely occurred at night. They were often attended by jaundice, which, however, rarely lasted longer than two or three days. There was tenderness in the right hypochondrium in both, especially after one of the attacks. The liver was not enlarged and no tumor could be felt when the patient was lying down. When standing up and leaning forward, supporting the weight of the upper part of the body on the hands, so that the abdominal muscles were relaxed, a sensation of deep resistance was felt over the region of the gall bladder, but the gall bladder could not be defined. The lower end of the right kidney could easily be felt in both patients when they were standing upright, but it was not movable in the ordinary sense of the term. In several other cases inflammation of the appendix was simulated very closely by movable kidney.

20. **Ethyl Chlorid Anesthesia.**—Hilliard describes the method of using ethyl chlorid, its dose, after-effects, clinical signs, and the preparation and posture of the patient. He considers this preparation an admirable anesthetic, either alone or with air, with nitrous oxid, with chloroform, with ether, with A. C. E. mixture, and as a preliminary to each of the last three for a large variety of surgical operations. It is contraindicated in diseases of the larynx, inflammatory lesions and tumors in, or adjacent to, the respiratory passages; goiter; all conditions giving rise to urgent dyspnea, and in long operations.

26. **Appendicitis and Pregnancy.**—The author's patient, aged 40, was seized with pains in the lower right half of the abdomen during the fifth month of pregnancy. Pain continued and was accompanied by constipation, but no vomiting. Poulticing relieved the pain for a few days, when it returned, accompanied by fever, constipation, swelling and tenderness in the right iliac fossa. She had had two similar attacks previously during pregnancy, and at about the same time. The diagnosis of suppurating appendicitis was made. An incision through the parietes in the usual place allowed the omentum to bulge forward into the wound. This omentum covered an abscess cavity containing about three ounces of pus. A gauze drain was inserted and the patient was put back to bed. Pregnancy was advancing and the movements of the child were both seen and felt, which did not tend to the formation of a good scar. Eventually, however, the wound closed. A month after the operation the patient miscarried, the child being dead. There were no complications, and the woman made an uneventful recovery. In view of the rapid growth of the uterus during the latter months of pregnancy, the author considered the advisability of procuring miscarriage. For some days after operation the wound seemed to get more and more extensive and gaping, and omentum was protruded. They felt that when the wound did heal several unpleasant possibilities might present during labor. The scar, recent and thin, might rupture; a large ventral hernia in all probability would form either during labor, with possible intestinal constriction as a result, or afterwards, in which case a second operation would be necessary for its cure. The risk of procuring miscarriage was thought to be sufficiently great to counterbalance what were, after all, only reasonable possibilities or probabilities, and nature finally and fortunately came to the rescue and solved all difficulties. Throughout her illness the patient had a singularly rapid radial pulse, and her temperature was almost uniformly subnormal and never rose above 99 except on three occasions.

28. The French at the St. Louis Congress of Sciences.—Out of the 130 presidents' and 260 official addresses at this international congress, 28 were representative Germans, 13 Englishmen and 15 Frenchmen. The Austrians numbered 8 and the Japanese 4, Italians 3 and Dutch 2, while six other countries sent one representative each, and the Americans numbered about 300. Courmont and Teissier are both of Lyons, France, and with these exceptions the other representatives from France were not officially connected with any medical faculty. Courmont compares this apathy on the part of the French with the systematic organization of an imposing representation invariably sent by Germany on such occasions. The French are not seen at these international gatherings, he remarks, and people forget that they are among the first, if not the first, in the medical sciences. Thirty years ago students flocked from America to Paris to complete their studies; now they go to Vienna, Leipsic or Berlin, and pass by France. One of the principal reasons for this is the excessive centralization of Paris. Foreigners do not know that there are a number of fine medical schools outside of Paris, one having 1,200 medical students. Invitations to participate in the congresses are sent to Paris only. If the invitations for Germany had been sent to Berlin alone there would not have been so many representatives at St. Louis. He concludes with the remark: "If our friends across the sea would remember that there are many universities in France they would have more visitors and more representatives of French medicine to respond to their invitations."

31. Variations in Virulence and Urinary Surgery.—Guyon comments on the comparative rarity of ammoniacal cystitis now; "retentionists" get along for years without local or general mishaps, notwithstanding their retention and the rich microbian flora in their bladders. The microbes are kept in a state of hypovirulence by the more frequent emptying of the bladder and its occasional disinfection with silver nitrate. The germs do not wax virulent under these measures, and as they are capable of attenuating the virulence of the germs, no surgical intervention should be attempted on the urinary passages until the virulence has been attenuated by these or by other measures. The operation, instead of being a very dangerous one in a field of hypervirulence, thus becomes a very benign intervention in a hypovirulent field. Prostatectomy, nephrectomy, lithotrity and suprapubic incision under these conditions, after attenuation of the virulence of the germs, do not expose the subject to operative shock, nor to exacerbation nor renewal of the febrile phenomena. The only operations which are best done without delay are those where it is necessary to open some septic focus from infiltration of urine or the like, merely a simple, rapid incision.

32. Pay Hospital for Contagious Diseases.—Faure suggests the advisability of establishing at Paris a well-equipped hospital for contagious diseases among the well-to-do. As each patient would have a separate room such a hospital would be expensive, and he adds that it might be better to have several small ones for each disease, measles, scarlet fever, diphtheria, etc.

34. Syringe for Injecting Cold Paraffin.—Broeckaert gives an illustration of his improved syringe which by the pressure of a screw forces out the cold paraffin in a soft, thin stream. Its advantages over other syringes of the kind are that only one hand is used. The screw is worked by an automatic lever which also serves as the handle for the syringe. By compressing together the two legs of this lever handle the screw is turned as rapidly as desired while the tip of the syringe is under complete control and the other hand is left free. He usually makes a pocket in the tissues with the tip of the needle to hold the paraffin before he injects it, and is enthusiastic in regard to paraffin prothesis as one of the finest acquisitions of modern surgery and. perhaps. one of the most fertile in its applications. He has sometimes obtained excellent results in the most discouraging cases by combining an autoplastic operation with the injection of paraffin.

35. Mechanical Purification of Milk.—Diffloth reports that great progress has been realized by the cotton filters, a Swedish invention, now used for purifying milk. The milk is strained through two wire strainers holding between them a flat, round, small sheet of cotton. The cotton is thrown away and replaced by a fresh disc of cotton after using. In eight months of tests with this cotton filter his inoculation of animals with the milk never caused morbidity, and the milk thus filtered could be kept for many days without souring. Diffloth regards the results of these tests as very remarkable in regard to the preservation of the chemical composition and of the digestibility of the milk, but as the milk was obtained from a model dairy they are not conclusive in respect to the microbes. Centrifugation has no effect on pathogenic germs in milk, or is liable to favor their proliferation. He adds that stock raisers have found it necessary to pasteurize "skim milk" from the creameries before feeding it to their pigs, as it is much harder to preserve than "skim milk" from natural cream rising. Centrifugation also interferes with what he calls the stereochemistry of the milk, that is the molecular arrangement of its constituents, and it has the further disadvantage that it expels the gases.

37. "Cardiac Liver."—Geraudel describes the pathologic anatomy of the congested liver in heart disease, commenting on the fragility of the liver in general and especially of the parenchyma surrounding the hepatic veins. The most remarkable feature of the "nutmeg" liver is the regional variation of the reaction of the organ to the injurious influences. The portal zone resists, but the zone around the hepatic veins rapidly yields. This imposes the necessity for guarding the subject with heart disease from any causes, alimentary, medicinal or of other origin, liable to reduce the resisting powers of the liver still farther, or to enhance the fragility of this zone around the hepatic veins.

38. Nascent State of Medicinal Substances.—Frenkel remarks in this continuation of his researches that each molecule of free oxygen contains two atoms, and the intraorganic oxidations occur only when the molecule has been split up into its atoms. Inside the body oxygen is split up into its atoms, which is the same as saying that it is in the nascent state. Ordinary oxygen in contact with the skin or taken into the stomach retains its molecular character and does not split up into atoms, but the peroxids do this. Hence their importance in therapeutics whether in the form of ozone (peroxid of oxygen), of peroxid of hydrogen, of magnesium or of zinc. These peroxids give up their oxygen, split into atoms, on contact with acids or ferments, and hence they allow, on the surface of the body, oxidations similar to the intraorganic vital processes.

39. Materials of the Urine.—Labbé presents arguments and data to corroborate the fact that the mineral substances in the urine owe their origin to the food. The proportion of chlorin, phosphorus and sulphur show the quantity and quality of the food taken. Exact knowledge of the diet and comparison of the ingesta with the excreta are indispensable for a proper study of the nutritive functions.

41. Lumbar Puncture in Ear Affections.—Babinski noticed that vertigo of aural origin was benefited by lumbar puncture. As the vertigo in such cases is due to irritation of the labyrinth, the idea occurred to him that the same measure might prove effectual in other affections of the labyrinth. He first established that rachicentesis does no harm from the standpoint of the ear. The occasional headache and nausea are transient and they are usually most pronounced in the subjects who derive most benefit from the intervention. He reports his experience with 106 cases thus treated. At first he allowed only 4 or 5 cm. of the cerebrospinal fluid to escape, but now he withdraws from 10 to 15. A single puncture is generally sufficient. but some patients require two or more. Out of 32 cases of vertigo, 21 of the patients were improved, including 7 who have been completely cured for six months at least. In 11 no benefit was apparent. The subjective symptoms were more rebellious. Out of 90 only 30 have found that the tinnitus was much improved. Deafness is still more rebellious, but occasionally cases were encountered in which the improvement seemed almost miraculous. In one case, a woman who had been deaf in one ear for six years subsequent to a suppuration, was able to hear the whispered voice at nearly seven feet. A man of 33 who had been a deaf mute from the age of two and a half, entirely deaf in one ear and almost completely deaf in the other, who had submitted to every imaginable form of treatment, was treated by puncture thrice repeated. No benefit was apparent after the first, but the second was followed by slight improvement, and now he hears the speaking voice at eight inches on the side in which the hearing had been supposed to be entirely lost. Pure labyrinthitis gives the larger proportion of successes, and in otitis media the phenomena due to irritation of the labyrinth are the ones most favorably influenced.

42. Carbonic Oxid Poisoning.—Strassmann and Schulz have been studying to learn if it is possible to distinguish between *poisoning from without and poisoning from within* by this agent, that is, whether it was inhaled during life or permeated the tissues after death. They experimented with illuminating gas, using the sensitive palladium chlorid test. The gas was introduced into the air-tight coffin holding the cadaver, and sometimes the tube was placed in the mouth. The results showed that there is no part of the body into which the carbon oxid does not penetrate in time, whether the gas is pure or diluted with air, stagnating or constantly renewed. A very *important sign* that the gas has penetrated from without is the difference in color of the hemoglobin in the muscles as they are nearer or farther from the surface of the body. There is no qualitative difference between the findings after carbonic oxid poisoning and of postmortem diffusion, but the quantitative difference is marked when the body has not been very long exposed to the gas. If completely saturated with it there may be no difference of any kind. In a recent case a woman was found dead with the tube of her gas stove in her mouth and the stopcock open. A relative asserted that criminal abortion had been forced on her and that the gas accessories were merely to divert suspicion. No traces of recent abortion could be discovered and tests for carbonic oxid in the blood aided in confirming the assumption of suicide.

43. Retrogressing Paralysis of Vocal Cords.—The postmortem findings in the case of fatal aneurism described and illustrated showed that the sac had become filled with coaguli during life. As they formed, the aneurism was not distended to quite the same extent as before, thus relieving the pressure which had induced the paralysis of the vocal cords.

44. Routes of Infection for Tuberculosis.—Wassermann believes that pulmonary tuberculosis frequently starts at some point in the lining of the mouth or throat or even in the ear. This lesion involves in turn the glands in the neck, the infection working downward and inward. The pleura is next involved and later the hitherto intact lung. This passage of the infection through the chain of organs to the intact lung and the tuberculization of the latter form a sequence which is frequently observed. He cites a few cases in illustration, among them that of a child with enlarged glands in the neck. The grandmother rubbed salve vigorously into the glands and the swelling subsided, but the bacteria forced out of the glands by the massage evidently passed into the pleura with resulting pleuritis, followed by infection of the lung. The assumption of this route for the infection needs to be confirmed by anatomic study of the lung apex *in situ*, not after it has been pulled out. If the findings were to indicate that the infection had been propagated from the parietal to the visceral pleura, then there could be no further doubt as to the correctness of this assumption.

45. Acute Articular Rheumatism in Children.—Baginsky has *never found the blood essentially abnormal.* The anemic appearance is probably due to the lessened blood pressure and the smaller amount of blood in the vessels. He protests against the dumping of chorea in the general receptacle for infectious affections—there are probably *two main groups*, the rheumatic and the nervous choreas. In 64 cases of chorea he found only 20 in which there were any rheumatic antecedents. *Aside from chorea, nervous manifestations were rare* in his experience with rheumatism except that cerebrospinal meningitis was sometimes associated. The distinguishing feature of acute articular rheumatism in children is the early and almost inevitable involvement of the heart. All except 7 of the 76 cases in his experience presented evidences of lively irritation or inflammation in the heart. In 17 cases there was apparently complete restitution of the heart, but in 41 others some cardiac defect developed sooner or later. The proportion of cases with intact heart was 12 per cent.; of complete recovery, 23 per cent.; of permanent heart defects, 62 per cent., and of deaths, 9.9 per cent. The postmortem findings demonstrated that the special and most prominent anatomic reaction of the heart in childhood to the irritation of the rheumatic virus is a fibrinous pericarditis with adhesions, and a tendency of the fibrinous exudated and proliferating products of the inflammation to become transformed into connective tissue, with the heart and pericardium completely grown together. The organism usually manages with this immovably fastened organ until the stress of puberty. Salicylic medication has no effect on the heart complications either for prevention or cure. He relates experiences with various drugs, including subcutaneous injection of carbolic acid, all to no avail. The only one that seemed to do any good was potassium iodid, from 1 to 3 gm. a day. This seemed to alleviate the symptoms of severe inflammation in cases of pronounced pericarditis and endocarditis. It sometimes had a magical action in reducing the fever, moderating the local inflammation and combating the most dangerous symptoms of the disease. His experience with antistreptococcus serum has been slight and rather unfavorable.

46. Diagnosis and Treatment of Cardiospastic Dilatation of Esophagus.—Strauss has modified his method previously described in these columns, and describes its mode of application and the results. One patient had presented symptoms of cardiospasm for ten years. The stomach tube introduced into the esophagus revealed evidences of stagnation. Pushing it farther down into the stomach evacuated food relics showing traces of digestion, entirely absent in the slimy mass removed from the esophagus. The sound with the inflated rubber bag afforded reliable information in regard to the size of the dilated esophagus. Its capacity was 350 c.c. in the typical case described. The sound projects into the stomach, and air blown through it can be recognized by auscultation. Pressure on the stomach region also disturbs the water in a connected jar. By this means it is possible to exclude a diverticulum, as in-case of the latter it would be impossible to push the sound down into the stomach without first withdrawing it a certain distance. The inflammation in the esophagus healed on removal of inciting causes, on resorting to rectal feeding and ingestion of oil, butter and minimal amounts of fluids, with tannin per os. Systematic stretching of the cardia was not undertaken until all symptoms of inflammation had subsided. The instruments used were all soft and flexible. One was a soft rubber tube with a hollow, spiral metal guide terminating 2 cm. from the tip of the tube. With this the esophagus was gently inflated as the tube was introduced, which has a tendency to open the cardia by the traction. When this appliance had been systematically used for a time he changed to one which has a spindle-shaped bag on the stomach tube. The air bulb is connected with this and the esophagus gently dilated. When the collapsed bag passes into the stomach its presence there can be determined by ascertaining that the tip of the tube projects into the stomach (auscultation of air blown in, etc.) The air bulb is then detached from the stomach tube and changed to a T tube. The rubber bag in the stomach is then inflated, the amount of air necessary to distend it to a circumference of about 9.5 cm. having been previously ascertained. Gentle traction on the stomach tube brings the inflated bag back through the cardia, accomplishing the dilatation. The air is then released and the apparatus withdrawn. Patients treated on these principles are soon relieved of all their disturbances, and in the typical case described the young man gained 28 pounds in six weeks. A woman with the esophagus dilated to a capacity of 550 c.c. was restored to health and gained materially in weight by a few weeks of systematic dilatation of the cardia in this way, although the capacity of the esophagus had not been much reduced. She has been free from disturbances during the year and a quarter since. The superior advantages of the appliances described are that the softness prevents injury of the lining, the pneumatic principle of inflating the esophagus renders it much easier for the bag to pass the cardia, and the larger circumference of the bag renders the dilatation more effectual, while a safety contrivance for the escape of the mercury prevents injury from too great pressure.

49. **Action of Roentgen Rays on Blood Affections.**—The experimental research on rabbits reported demonstrated that close exposure to *x*-rays causes the myeloid and lymphoid cells to vanish from the bone marrow while the red corpuscles remain unaffected. The findings confirm the clinical observation that pernicious anemia is not influenced by Roentgen treatment while leukemia is liable to show marked improvement owing to disappearance of the lymphoid and myeloid tissue. Red corpuscles suspended in salt solution and exposed for two hours to the rays were apparently unaffected by them.

50-51. **Mechanical Dilatation of Esophageal Stricture.**—An impermeable cicatricial stricture of the esophagus in a girl of 17 was dilated with a Crawcour spiral sound introduced for a quarter of an hour daily until fluids could be ingested. Further dilatation was accomplished with Senator's swelling sound, that is, a sound on which a laminaria tent is fastened. About fifteen minutes after its introduction the patient feels the pressure of the swelling tent in the stricture; when it becomes unbearable the sound is removed. The success of this mechanical dilatation was most striking. In six weeks the patient was eating normally and gained 66 pounds in seventy days. Richter's article reports the findings in regard to the metabolism during convalescence.

52. **Experimental Production of Lymphocyte Exudates.**—Wolff recalls that Senator in 1893 was the first to suggest the possibility of an active lymphocytosis. He proposed this as an explanation for the finding of lymphocytes in the urine in certain cases of nephritis. Wolff has been seeking some means of influencing the lymphocytes and of inducing active lymphocytosis by chemotactic or other means. He first undertook research to determine whether the lymphocyte reaction is of the same biologic importance in different species, and whether the agents found to induce lymphocytosis in one have the same action in other species. The results demonstrated that injection of tetanus and diphtheria toxin is able to induce exudation of lymphocytes, persisting for one to twenty-four hours after the injection. The mouse has a special tendency to lymphocytosis. The substances which induce polynucleosis in the guinea-pig cause lymphocytosis in the mouse. A peritoneal injection of .1 c.c. of one of these toxins produces active lymphocytosis at will. In the guinea-pig similar injections cause lymphocytosis at first, gradually changing to polynucleosis after the first hour.

57. **Radical Operation for Femoral Hernia.**—Hammesfahr closes the femoral canal by fastening Poupart's ligament to the crest of the horizontal ramus of the pubis. After the hernial sac has been resected and the stump reduced, he drills three holes in the upper margin of the ramus. They are drilled from the front and slant upward so that the inner opening is close beneath the edge of the crest. Strong silk is then passed around Poupart's ligament and then through the holes and tied firm. This fastens the ligament to the bone like the periosteum, and it probably becomes adherent. The ligament can be said to start at the crest of the pubis, toward the median line from the femoral vein. Aseptic healing can be counted on if silk, boiled and kept in Claudius' 1 per cent. iodin-iodid solution, is used and thread gloves worn.

63. **Joint Tuberculosis and Trauma.**—Petrow gives illustrations of the joints of animals after peritoneal inoculation of tubercle bacilli. The joints and epiphyses were clinically and macroscopically intact, but the microscope revealed tubercle bacilli latent in the marrow of the epiphyses in 14 out of 312 sections, the positive findings being from 8 animals which had succumbed to tubercular peritonitis four or five weeks after inoculation. Further experiments with infected joints exposed afterward to trauma demonstrated the unmistakable action of trauma in accelerating the progress of the infection. In another series of experiments he established that a severe trauma affecting a joint is liable to favor the localization at this point of chronic tuberculous infection.

65. **Woody Phlegmon of Neck.**—Merkel describes a typical case of Reclus' "phlegmone ligneuse" developing in the course of four months. The process evidently started in the tonsil and burrowed outward, spreading under the skin and inducing dyspnea and dysphagia, pain and slight temperature. An incision was made in the hard, woody tumor, under chloroform, and a tablespoonful of pus evacuated, after which the tumor rapidly softened and in two months not a trace was left. The patient connected the tumor with the fact that he had held a knife for a few moments in his mouth after he had just slaughtered with it a cow presenting lesions of actinomycosis. But nothing about the phlegmon suggested an actinomycotic process.

66. **Ultimate Results of Anterior Utero-Vaginal Incisions.**—Bardeleben reports 8 cases examined for the remote results of rapid dilatation by means of an incision through the portio and vagina. There was no hemorrhage, no discharge in any instance, nor retroflexion, and in only 1 was anteposition and in 2 retroversion with anteflexion noted. The advantage of the incision is that one can control the evacuation of the uterus in a given time, and the wound is in the best possible condition for repair. Instrumental dilatation is under less complete control, and in case of unyielding tissues there is danger of laceration, after which the prospects for repair are much less favorable.

67. **Extramedian Symphyseotomy.**—Leopold has performed the Gigli operation in 5 cases recently. It proved simple and easy of execution and the lying-in period was free from complications of any kind. He gives the details, the results confirming Gigli's assertions in every respect.

69. **Gigli's Technic for Extramedian Symphyseotomy.**—Gigli qualifies ordinary symphyseotomy—from the surgical standpoint—as not a proper operation. His technic of extramedian symphyseotomy, however, is free from all its disadvantages while securing all that is claimed for it. The incision must be to one side of the articulation of the symphysis, and it must also be outside of the point of attachment of the pubovesical ligament. The line that best respects the relations between the bladder and the pubis, etc., is drawn from the tuberculum below, slanting upward toward the median line above, lying entirely along the bone. This avoids the points where the abdominal wall is weak and leaves the cartilaginous apparatus intact. It is well to draw the skin down so that there will be as much space between the incision and the genitalia as possible. The soft parts are then incised down to the bone, and then mobilized a little at top to allow the finger to feel the upper margin of the pubis. A blunt-pointed, curved needle is then easily passed from above behind the bone in the direction of the incision, and, guided by the finger in the vagina, it emerges at the proper point below, entirely avoiding the crura clitoris. There are no large vessels at the back of the pubis, and the needle curves up readily around the lower margin of the pubis. The wire saw is then fastened in the needle, which is then drawn back, the bone sawed and the operation is done. Both the immediate results—the absence of complications—and the remote—the permanent enlargement of the pelvis with no interference with the gait—speak in favor of this operation first made possible by Gigli's wire saw. He insists that it should be called "Lateralschnitt des Beckens," which may be translated "lateral section of the pelvis." Others call the operation "hebotomy," from the Greek term for pubis. [For convenience in indexing, the term extramedian symphyseotomy seems preferable for the present.—Ed.]

74. **Symptomatology of Movable Retroflexion.**—Nacke found that 14 per cent. of 265 patients with movable retroflexion and otherwise apparently normal genitalia had no symptoms whatever from the backward displacement. Of the others. 66 complained of backache alone, 37 of backache and other symptoms, and 125 of every possible symptom. The retroflexed uterus does not seem to cause disturbances so long as it is not enlarged and is free from pathologic changes. In case of congestion of the organ, increasing its size, or of irritation of its peritoneal investment from running, dancing, working the sewing machine, etc., the retroflexed uterus gives rise to pains which probably would not be the case if the organ were in anteflexion. The symptoms observed are probably due to slight changes in the tissues or in the nervous apparatus of this region from these causes.

78. **Hemorrhage from Varices During Pregnancy.**—Kubinyi has observed a case of complete retention of urine after sudden hemorrhage from the bladder at the eighth month of a pregnancy, the outlet of the bladder having become obstructed with a thick clot. The hemorrhage was traced to a varicose enlargement of one of the veins in the bladder. In another case an almost fatal hemorrhage occurred from a varix on the leg of a pregnant woman.

80. **Eucain-Adrenalin Local Anesthesia.**—Freund relates his experience with local anesthesia with a mixture of 2 parts of 1 per 1,000 adrenalin to 8 parts of a 1 per cent. solution of beta eucain, injected under the skin or mucosa or both. He regards it as indispensable for prolapse operations and for plastic operations on the perineum. No by-effects were ever observed in his extensive experience except that a few extra sensitive patients complained of transient smarting.

82. **Cure of Paget's Disease.**—In the case described, the affection known as Paget's disease of the nipple was located in the axilla. For this reason the authors suggest that the disease had better be called by a more descriptive name, and propose "chronic, circumscribed, eczemiform epithelial dermatosis." This term corresponds with the histologic findings which they describe in detail. The lesion was so extensive in the case reported, measuring 13 by 20 by 27 cm. in extent, and involving the upper arm and both the front and back of the chest, that the surgeons declared it inoperable, especially as the patient, a ix-para, was very cachectic. Excised scraps from the deeper part of the lesion showed the elements of a squamous-celled carcinoma, evidently originating in the epidermis. Roentgen treatment was applied, exposing the entire region in a single sitting to a radiation of 4 chromoradiometer units and the deeper parts to from 8 to 10 units. After two or three weeks a reaction of the first degree developed all over the lesion and as this subsided the lesion healed. In less than four months *nothing* was left of the cutaneous lesion but a few narrow strips, and in the depths of the affection exhibited progressive improvement. The general health improved, the patient has gained in weight, and the blood findings are nor-

mal. A further exposure of 3 to 4 units was made four months later, and again after a few weeks, one small strip in the axilla being treated with radium.

83. **Radium Therapy.**—Lassar gives illustrations of a number of patients with melanoma or cancroid cured by application of 1 mg. of radium bromid in a small capsule of lead foil on a sheet of mica. He thinks that his experience justifies him in proclaiming that neoplasms can be cured with radium in the hands of any physician. Although the first expense of redium is high, yet as its energy is inexhaustible, on the whole, it is cheaper than some other methods of treatment. All mishaps from its use can be confidently avoided by suspending the treatment at the slightest symptom of irritation, swelling, redness, pigmentation or tenderness. Medical oversight is imperative and the rather tedious exposures must not be left to subordinates. During the thousands of sittings in his institute no inconveniences of any kind were noted, and the results observed indicate that radium has a wide field of usefulness in dermatology. He is also enthusiastic in regard to the efficacy of Roentgen treatment of cancer. It frequently transforms an inoperable into an operable lesion, and is almost certain to cure the incipient recurrences of the growth. They are usually more superficial than the primary lesion. He cites a number of cases in detail, among them that of a woman of 50 who appeared nine months after radical extirpation of a mammary cancer. The growth had recurred in the form of numerous ulcerating nodules, the size of a pigeon's egg, scattered over the region from the axilla to the median line and down to the waist. His illustrations show that the nodules entirely retrogressed under the *x*-rays, and the patient has gained more than six pounds.

85. **Embolism from Mercury in Paraffin.**—Voss states that in a material of 1,373 persons treated with 13,671 injections of insoluble mercurial salts, suspended in paraffin, embolism occurred fifteen times. The proportion was one embolism to each 91 subjects. The salt generally used was Hg. salicylate in a .05 or .1 per cent. suspension in paraffin. The symptoms were invariably slight and transient, and embolism may be regarded as a harmless complication. The injections were always intramuscular.

87. **Hot-Water Treatment of Gonorrhea and Soft Chancre.**—Sadger reiterates that the application of heat reduces the length of treatment by one-half or more; it entirely prevents glandular enlargement; renders a bubo non-virulent, and insures its rapid healing after evacuation. It is not effectual before incision. The application of heat alone is better than to combine it with medication. Welander has thus treated more than 2,000 soft chancres, and the results were invariably most favorable. K. Ullmann's hydrothermoregulator is proving a simple and convenient mode for local and self-regulating application of heat in the form of hot water continuously circulating in an endless tube.

89. **Further Inoculation of Ape with Syphilis.**—From the illustrations given by Lassar it seems to be evident that he has succeeded in inoculating a second chimpanzee with syphilis, the virus being taken from the first chimpanzee previously reported. He thinks that these results offer a prospect for obtaining an effectual antisyphilis serum from chimpanzees in time.

97. **Prescribing of Yellow Oxid Salve.**—Schanz presents various arguments to show the defects in the current modes of prescribing and making yellow oxid salve. His improved formula is: Hydrarg. oxyd. flav. recent. pur. pultiform .1 to 1 gm.; aq. dest. and adip. lanæ anhydric., āā, 1 gm.; vasel. amer. alb. 10 gm.

99. **Cathode Rays as a Substitute for X and Radium Rays.**—Strebel announces that the cathode rays act like the radium rays, and may substitute the latter in radiotherapy. He further describes his mode of photo-cauterization and commends it as a valuable means of treatment of lupus, cancroid and similar affections. His experience has also been very gratifying with local applications of the ultraviolet rays in the urethra to induce hyperemia as a means of treating gonorrhea.

104. **Symptoms of Paralysis of the Sympathetic.**—Rosenfeld describes a case of cancer of the esophagus causing paralysis of the right sympathetic and left recurrent laryngeal nerves. Besides the usual symptoms he mentions a remarkable hyperemia of the opposite side of the face, and the anidrosis and reaction of the pupil to pain, observed on the affected side.

105. **Tonic Reaction of Pupils Not Reacting to Light.**—Roemheld's patient presented evidences of old phthisis and exophthalmic goiter, no syphilis. The pupils were unsymmetrically dilated, without any reaction to light. During accommodation, convergence and closing of the lids, they contracted with great rapidity and completeness, and persisted in this condition for a long time, resuming their former condition very gradually. There were no other indications of a spinal affection. This phenomenon has been observed to date in congenital lues, multiple sclerosis, tabes, diabetes, alcoholism, migraine and paralysis. Its significance for diagnosis and prognosis is still undetermined.

106. **Postdiphtheritic Nephritis.**—Mayer has witnessed a couple of cases of acute nephritis commencing the second week of diphtheria. He thinks that postdiphtheritic nephritis is more common than supposed, but generally escapes notice. The urine should be examined long into convalescence to detect albuminuria.

108. **Climatic Influences on Asthma.**—Avellis relates a few instances from his experience to show the contradictory action of change of climate in cases of asthma. In one instance a child had been permanently relieved of the asthma by a trip to a certain place in the country. There was no recurence of the asthma, but a year later the child was taken to this same place and at once the asthma returned and persisted until after the return home. In another case a change of air always brought on asthma; in a third, a place where the patient had always been free from asthma brought it on as soon as she arrived there. A fourth patient with very severe, almost constant, asthma, was permanently relieved by a two-hour journey to a hill country and the same place always proved "asthma immune" in her case. Another asthmatic lived in Heidelberg and suffered much from asthma, but was always relieved when he climbed to the top of the high hill there. Some do best in high valleys, others on the plains, some even in the London fogs. Sea air seems to have an unfavorable influence except for children, whom it frequently benefits. Mountain air sometimes helps children.

THE OCULAR SYMPTOMS OF LESIONS OF THE OPTIC CHIASM,

WITH THE REPORT OF THREE CASES OF BITEMPORAL HEMIANOPSIA.*

G. E. DE SCHWEINITZ, A.M., M.D.
AND
JOHN T. CARPENTER, M.D.
PHILADELPHIA.

In order to study the ocular symptoms of lesions of the optic chiasm, the following classification, although somewhat artificial, naturally suggests itself:

1. The anatomic relations and structure of the optic chiasm.
2. Anomalies of the visual field.
3. Ophthalmoscopic changes.
4. Anomalies of the external ocular muscles.
5. Alterations in the pupil reflexes, with special reference to the hemiopic pupillary inaction.
6. The lesions which produce alteration in the structure and function of the optic chiasm and give rise to the ocular symptoms from which their position is inferred.
7. Diseases of the pituitary body, with special reference to the ocular symptoms of acromegaly.
8. Simulation of chiasm disease by other affections, for example. hysteria, locomotor ataxia, brain tumors.
9. The effect of certain toxic agents in causing lesions of the optic chiasm.

ANATOMIC RELATIONS.

Beneath the floor of the third ventricle the optic chiasm rests in the optic groove of the sphenoid bone. Its important anatomic relations are ventrally the sphenoid bone, dorsally the third ventricle of the brain and posteriorly the hypophysis with its prolongation, the infundibulum. The circular venous sinus and the internal carotid arteries, with their anterior cerebral branches, are in close surgical relation to the chiasm.

Microscopic Structures.—As is well known, there has been considerable difference of opinion in regard to the disposition of the fibers in the optic chiasm, whether on the one hand there is total crossing of the fibers, as Michel and von Kölliker believe, or whether, according to the majority of authors, there is, as a rule, a partial decussation. The literature of this subject, often involved and contradictory, has been best analyzed in comparatively recent times by Llewellys Barker.[1] and we can not do better than quote in a somewhat condensed manner from his admirable review as follows:

> The long processes, or axones, of the ganglion cells pass into the nerve fiber layer of the retina, reaching the papilla or nervehead, and proceed to the optic nerve. Having reached the optic chiasm, a portion of the fibers of one optic nerve cross over and enter the optic tract of the opposite side, forming the crossed fasciculus, while a certain number of other fibers do not cross, but enter the optic tract of the same side, forming the noncrossed fasciculus. The noncrossed fasciculus arises chiefly from the temporal side of the retina, while the crossed fasciculus arises from the ganglion cells of the nasal side of the retina. The bundle of the macula lutea, or papillo-macular bundle, in general terms, is situated in the central part of the optic nerve and maintains its central position in the optic chiasm and in the optic tract, and is composed of crossing and direct fibers.

Now, although secondary degenerations observed in pathologic cases in higher animals and in human beings seem to prove a semi-decussation and not total crossing of the optic chiasm, and although von Gudden has shown that in the rabbit, where the decussation is almost total, there is a small non-crossed fasciculus and that total decussation is present only in such animals in which the visual fields of the two eyes are entirely separate, for example, in fish, amphibia and birds, von Michel asserts that even in man the decussation is complete or total. He bases his opinion on serial sections of the normal optic chiasm, on sections of the optic nerves, chiasm and tracts, in cases of degeneration in men and animals; and on certain physiologic considerations.

Apparently, however, his views are not tenable when taken into consideration with the great mass of evidence which has accumulated on the opposite side. Von Gudden, with careful consideration of the superior commissure of Meynert, the inferior commissure of Gudden, and the hemispheric bundle, has demonstrated by unobjectionable methods,that each of these,as well as the crossed fasciculus and the non-crossed fasciculus, can be individually isolated. He has shown that the well-known experiments of Nicati, by which the optic chiasm was cut in the middle through the mouths of cats, demonstrate that these cats could still see, which would be difficult or impossible to explain if the decussation was total, and in Siemerling's case of destruction of one optic tract with diminished sharpness of the opposite eye, the patient could still see with the temporal side of his retina. also an impossiblity if complete decussation had been present.

Finally, we come to the studies of Henschen, based on elaborately studied and collected clinical material. According to this observer, whose views are accepted by almost all modern writers on the subject, the following is the arrangement of the fibers in the chiasm: The macular fibers. both crossed and uncrossed. are axial in situation. the crossed bundles being central while the uncrossed bundles are found medial and lateral. The papillo-macular bundle, although mainly axial, almost reaches the periphery behind the center of the chiasm where the crossing fibers are exposed to injury by a circumscribed lesion in the median line. The fasciculus cruciatus from each optic nerve is found on the dorsal and ventral aspects; while the *fasciculus non-cruciatus* is found medial and lateral.* In addition, the chiasm at its posterior angle contains two sets of commissural fibers not concerned in vision—the superior commissure of Meynert and the inferior commissure of von Gudden.

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

[1] The Nervous System and Its Constituent Neuroses, 1899, p. 782.

While it is undoubtedly true that this represents the usual anatomic arrangement in the chiasm, individual differences of great variety are possible, and indeed, have been found, varying from the entire absence of the chiasm (the right optic nerve going to the right tract and the left nerve to the left tract), to perhaps total decussation in the chiasm. (Fig. 1.)

ANOMALIES OF THE VISUAL FIELD IN CHIASM DISEASE.

The literature of this subject is extensive, and although we have examined it with some thoroughness and carefully analyzed between forty and fifty of the most important papers, it does not seem profitable in a communication of this character to do more than present a condensed statement of the possibilities in visual field changes without detailed reference to individual cases.[1] Moreover, the entire subject has been dealt with in so masterly a manner by Wilbrand[2] that it would be impossible to avoid quoting him as freely as we have in the section which follows:[3]

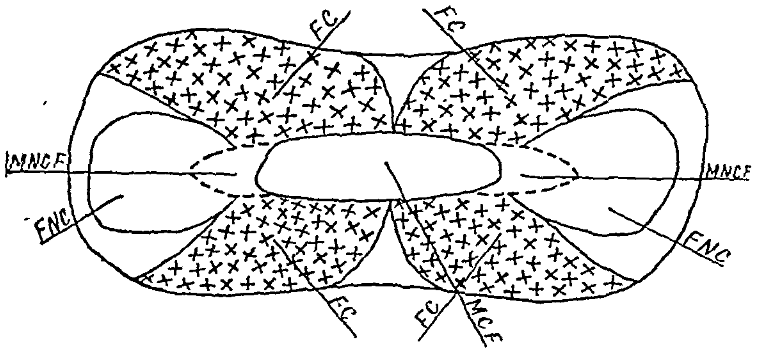

Fig. 1.—Henschen's arrangement of the fibers and chiasm according to Barker: f. c., crossed fasciculus; f. n. c., uncrossed fasciculus; m. n. c. f., macular non-crossing fibers; m. c. f., macular crossed fibers.

Complete Bitemporal Hemianopsia.—The most characteristic alteration of the visual field which may be regarded as pathognomic of chiasmal lesion is bitemporal hemianopsia, which, with its various modifications, is called by Griffith "the localizing form of hemianopsia." In a typical example there is blindness of the temporal halves of the visual field, with preservation of the normal function of the nasal halves, the dividing line making a sharp, vertical separation between the two portions of the field of vision. (Fig. 2). Instead of loss of the temporal field exactly to the fixation point, a portion of the field may be retained beyond this position, i. e., the line of separation does not lie in the vertical meridian.

This "over-shot field of vision," as it has been called, suggests the supply of the macula with a double set of nerves, one from each hemisphere, and has been explained by Schmidt-Rimpler by assuming anastomoses of the fibers in the optic nerves and chiasms. An interesting fact is the occasional long unchanged duration of bitemporal hemianopsia, as in Förster's[4] case, where with complete loss of the temporal fields those on the nasal side remained unaltered for ten years. In these typical cases, not only does the nasal field for form remain unchanged, but the color-limits of the same sides are also preserved and coincide with the vertical separation. The temporal field defect is not necessarily complete *ab initio;* it may begin with loss for colors only, to be followed later by loss of form sense and light sense, or the form sense and color sense may be lost, and the light sense retained entirely or in part.

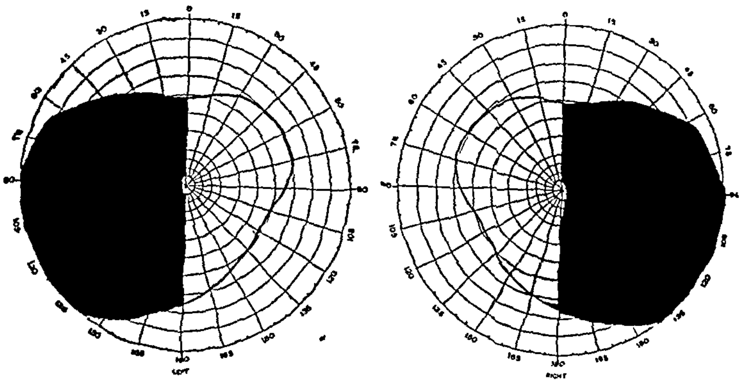

Fig. 2.—Typical bitemporal hemianopsia.

Again, the process may begin with paracentral or bitemporal hemianopic scotomas, which gradually broaden into bitemporal hemianopsia. Such cases, according to Wilbrand, have been reported by Beer, Förster, and Vossius.[5] In the last-named author's case, the condition began with bilateral temporal contraction of the visual fields and paracentral scotomas, and was followed by sharply limited bitemporal hemianopsia (Fig. 3).

Finally, the original condition of bitemporal hemianopsia may change and result in symmetrical paracentral hemianopic scotomas, as in Treitel's[6] case, which is quoted by Wilbrand. (Fig. 4).

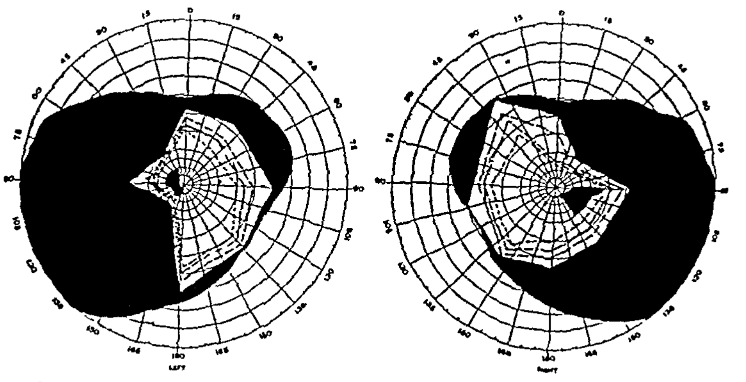

Fig. 3.—Bitemporal contraction of the visual fields and paracentral scotomas, followed later by bitemporal hemianopsia, after Vossius.

Significance: Typical bitemporal hemianopsia of permanent character is caused by a lesion which destroys the function, or, as it is called, the conductivity of both crossed fasciculi, leaving the non-crossed fasciculi unaffected. The best reported case of this character has been recorded by Weir Mitchell and Dercum,[7] in which an aneurism destroyed the center of the chiasm and obliterated the function of the crossed fasciculi. Paracentral or hemianopic scotomas indicate that the lesion is confined to that point on the dorsal surface of the chiasm where the papillo-macular fibers of the crossed fasciculus are interwoven.

[7] Jour. Nervous and Mental Disease, vol. xiv, 1889, p. 44.

Bitemporal hemianopsia subject to fluctuations in the extent of the visual disturbances depends on the basal disease, especially syphilis, as has been pointed out by Oppenheim.[8] Improvements, even to complete recovery, may be followed by subsequent loss of vision. In such a case as Treitel's, previously quoted (See Fig. 4), Wilbrand suggests that a basilar gummatous meningitis may have injured the crossed fasciculus, while an interstitial neuritis may have caused atrophy at the intersection of the papillo-macular fibers.

In this connection we briefly refer to two cases of bitemporal hemianopsia with autopsy:

BASAL GUMMA AND BITEMPORAL HEMIANOPSIA.

CASE 1.—This case one of us (de Schweinitz[9]) has already reported briefly.

History.—The patient, a colored man, in the wards of Dr. H. C. Wood in the Philadelphia Hospital, was a syphilitic aged 55, who had epileptic attacks, Jacksonian in type, partial loss of hearing on one side, demonstrable loss of taste and smell, partial hemianesthesia and hemiplegia. Wernicke's pupil symptom could not be demonstrated. Both nerves were atrophic, and there was complete bilateral temporal hemianopsia,, with marked contraction of the preserved fields (Fig. 5).

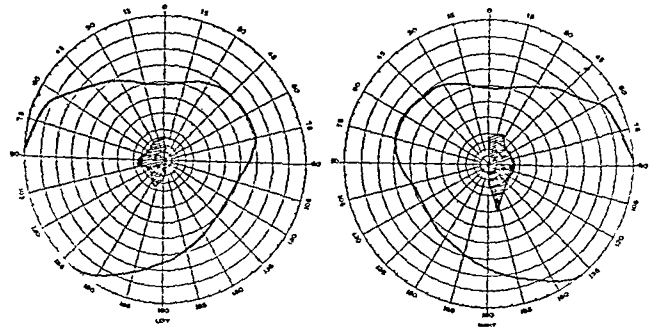

Fig. 4.—Symmetrical paracentral scotomas, after Treitel

Autopsy.—At the postmortem examination a band-like gumma was found which stretched across the anterior end of the pons and reached to the cribriform space. One end of the tumor was thicker and heavier than the other. The corpora quadrigemina and optic tract and chiasm were involved. Microscopic examination was not made.

TUMOR OF CHIASM; METASTASIS FROM MAMMARY CARCINOMA; BITEMPORAL HEMIANOPSIA.

CASE 2.—This patient, a woman between 50 and 60 years of age, was examined by one of us (de Schweinitz) in consultation with Drs. Tyson and Mills, who will report the case in detail. It is now referred to as a typical example of temporal hemianopsia in which a growth secondary to a carcinoma of the breast was situated at the base of the brain and involved in the chiasm. The visual fields (Fig. 6) indicate that the crossed fasciculi were divided. Dr. Spiller's examination of the specimens is as follows:

Autopsy.—The findings in the chiasm of Mrs. G. are as follows: The sella turcica was much enlarged and was about one and one-half inches in width from side to side, and about one inch from before backward. A large tumor mass filled the sella turcica, and the tumor was larger on the left side than on the right. The tumor extended around the optic chiasm and grew from behind it, and extended backwards almost as far as the anterior part of the pons. The right optic nerve was not imbedded in the tumor, but the tumor grew into the left orbit and surrounded the left optic nerve.

Microscopic Examination.—This showed that the tumor was a carcinoma, and that the optic chiasm was much degenerated by the invasion of and pressure from the tumor.

Temporal Hemianopsia of One Eye and Partial or Complete Blindness of the Opposite Eye.—Partial or complete blindness of one eye, with loss of vision in the temporal field of the opposite eye, has been reported a number of times. Thus there may be temporal hemianopsia of one eye, with entire loss of vision in the opposite eye, except in its upper or lower nasal quadrant; or the loss of vision in the opposite eye may be complete for color or form, but partially retained for light in one nasal quadrant; or, finally, the loss of vision in the opposite eye may be absolute. Cases of this character have been reported by Hirschberg, Lang and Schoen.

Significance: Under these circumstances the clinical picture is significant of a spreading lesion gradually involving the entire chiasm. Thus, if the upper or lower quadrant of the nasal field of the opposite eye is lost, in addition to its temporal blindness, it means that the disease has spread to the areas of the chiasm represented by the loss of visual function.

In this connection we record the following case already briefly reported by one of us (de Schweinitz[10]).

CASE 3.—A man, aged 34, clerk, American by birth, presented himself on Nov. 3, 1903.

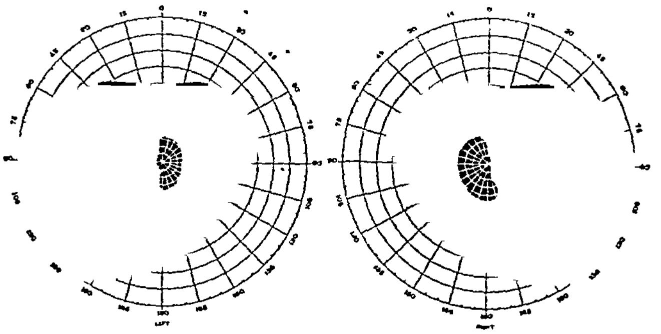

Fig. 5—Bitemporal hemianopsia and contraction of preserved visual fields from a patient under care of H. C. Wood. The lesion was basal gumma.

History.—The patient's father and mother are living, as also are four brothers and one sister, all of whom are in good health and have no organic defects of vision. Since an attack of dysentery at the age of 2 he has enjoyed good health, history of severe illness being absent. In 1883 he fell from a horse and was injured on the forehead over the left eye, but the skull was not fractured, so far as is known. The patient has led a healthful life, has no drug habits and denies venereal taint of any kind. His eye sight gave him no concern until seven years ago, when it began to fail, first on the left and later on the right side, the defect in vision being manifest by loss of the visual field on the temporal sides. There was never at any time pain, headache or signs of ocular inflammation.

General Examination.—The patient was undersized, but well nourished and presents all of the physical signs of infantilism of the myxedematous variety. With this exception, examinations made by us, as well as by other physicians, failed to find signs of organic disease. The urine was normal.

Examination of Eyes.—The eyelids were slightly puffy, and there was a moderate conjunctivitis of the left eye. V. of R. E. with + 0.75 sph. 6/7.5; amplitude of accommodation, 6 D. The optic nerve was ophthalmoscopically a narrow, vertical oval and atrophic, being bounded on its outside by a widened scleral ring; the veins were rather fuller than normal and were faintly streaked with white lines; the arteries were unchanged in size, both sets of vessels carrying normally tinted blood. Distinct evidences of neuritis were lacking and there were no gross changes in the retina or choroid. The visual field for form and colors exhibited the typical chart of temporal hemianopsia, the preserved form field (1 cm. square of white) being normal in extent, while the color fields (red and green) are markedly contracted, the dividing line exactly following the vertical meridian, the macular representation being in the preserved field (Fig. 7). The light field was preserved, except the upper and outer quadrant, which was entirely dark. The direct light reflex of the pupil was preserved, the consensual reflex absent, and the hemiopic pupil inaction (Wernicke's sign) could not be demonstrated, although the response was not so prompt when the light was directed on the blind side of the retina as when it fell on the opposite side.

---

[8] Mills, Univ. of Penn. Med. Bulletin, May, 1904, p. 110.

[9] Jour. of Nervous and Mental Disease, vol. xiv, 1887; also Nervous Diseases and Their Diagnosis, by H. C. Wood, p. 271.

[10] Ophth. Record, vol. xiii, 1904.

V. of L. E. was *nil*, light perception being absolutely lacking. The optic disc ophthalmoscopically was small, round and entirely atrophic, but there was no marked decrease in size of the retinal vessels, and as on the other side, no distinct signs of a previous neuritis. The direct light reflex of the pupil was, of course, absent; the consensual reflex preserved;

Examination of Nose and Throat.—Examination of the rhino-pharynx and sinuses by Dr. Walter Freeman yielded negative results, who writes: "I find no evidences of sinus or nasal disease which could account for the eye trouble; I believe the sphenoids and ethmoids are normal."

Examination of the Head.—Examinations of the cranium by means of the *x*-rays were made by Dr. Henry Pancoast at the Hospital of the University of Pennsylvania, and the skiagraphs showed a shadow directly in the position which would be occupied by the chiasm, which shadow was not present in a skiagraph of the normal head, kindly loaned by Dr. Pancoast.

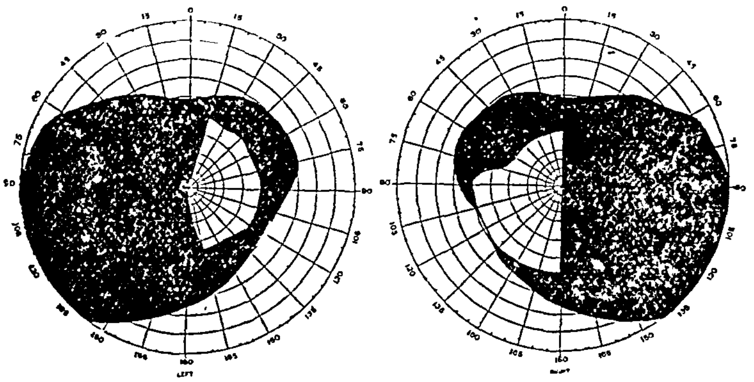

Fig. 6.—Bitemporal hemianopsia; tumor involved chiasm.

Remarks.—In the present instance we evidently had to deal with a case which was originally bitemporal hemianopsia, because the patient's statement accurately described the loss of the temporal side of each visual field as his first visual disabilities. Gradually the degeneration of the optic nerve continued, until on the left side the blindness became complete, and there is now temporal hemianopsia of the right eye for form and color and with a partial retention of the light sense, that is to say, it is preserved in the lower temporal quadrant and completely on the nasal side. In other words, we had here a very good example of a spreading lesion, so that only the nasal field of one eye remains perfect.

As to the probable lesion, three possibilities may be named, and in studying them we have had the advantage of Dr. William Spiller's examinations, who saw the case in consultation: 1, Myxedematous enlargement of the pituitary body; 2, as the patient once suffered from tapeworm, cysticercus of the chiasm; 3, aneurism or tumor at the chiasm.

What the exact lesion is is purely speculative, except there can be no doubt that the optic chiasm is involved. Sphenoid disease, which we first thought of, seems to be eliminated by Dr. Freeman's report. Dr. Pancoast's skiagram seems to show a shadow approximately in the region of the chiasm, a shadow, moreover, which is abnormal and which may indicate a growth, for example, an exostosis. Naturally, the injury which this patient received when he was thrown from a horse suggests the possibility that there may have been a fracture extending into the sphenoid bone. It is, however, difficult to accept this explanation in view of the fact that the injury occurred twenty years ago, while his visual defects were noticed only seven or eight years ago. Specific history is denied and there was no response to antisyphilitic treatment. He seems to have improved slightly in his general condition under the influence of thyroid extract. There has been no change, however, in the visual defects and also no progression.

Bitemporal Achromatopsia with Central Scotoma for Colors.—As already noted, the defect in the temporal fields may begin with loss for colors only, followed later by loss of form and light sense. In a case reported by Benson,[11] in addition to a bitemporal defect for colors, there was a scotoma for colors. The patient had acromegaly and was an excessive smoker. Sometimes, it would seem, there may be simply scotoma for color on one side, for example, in Doyne's case,[12] while on the other the scotoma is absolute.

Significance: In these hemiachromatoptic cases we may assume the interference in the conduction of the fibers involved has been sufficiently great only to lead to an inability to recognize colors, for example, red and green. Greater disturbance would lead to inability to recognize blue. As the power of conductivity grows less and less perfect, the patient gradually fails to distinguish black from white, and finally when it is lost the perception of light is lost.[13]

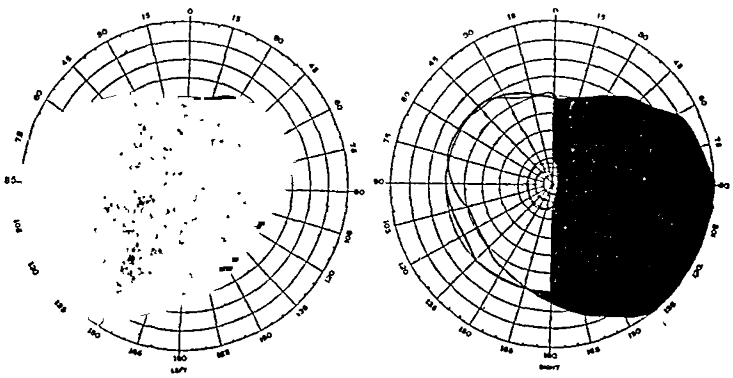

Fig. 7.—Temporal hemianopsia of right eye; complete blindness of left eye.

Chiasmal Central Amblyopia.—The development of bitemporal hemianopsia from symmetrical paracentral scotomas has been described. But it would seem that central scotomas, very difficult to distinguish from those seen in toxic amblyopia, are sometimes the initial signs of chiasm disease. According to Nettleship,[14] "the loss of the central field in the earlier stages is more abruptly defined than in tobacco amblyopia, and the symmetry is less precise, both in time and degree than in the latter disease." In one case in which a postmortem examination was obtained and the chiasm incorporated in a cyst, there was a central scotoma of oval shape, beginning just outside the fixation point, and extending twenty degress outward; the peripheral fields were intact.

Irregular Losses in the Visual Field.—A number of case records have been published describing irregular losses of portions of the visual fields. To some of these reference has already been made. Wilbrand has arranged them as follows: Temporal hemianopsia of one eye with loss of the upper outer quadrant of the visual field in the other (Schoen); temporal hemianopsia in one eye, in the other loss of the lower outer quadrant of the nasal visual field (Lang); loss only of the upper and outer quadrants of both fields; loss only of the lower and outer quadrants of both visual fields; loss of both visual fields, except their upper nasal quadrants which remained active; finally, loss of both visual fields, except their lower nasal quadrants which remained active is conceivable, although no such case has been reported. These irregular types of visual field defects are due to circumscribed lesions affecting small bundles of fibers in the chiasm. It is again to be noted that irregular losses of the visual fields with transient and varying types of bitemporal hemianopsia usually mean syphilitic meningitis, or gummatous involvement of the chiasm, in which recovery of vision often results from the administration of iodids or mercury.[15]

[14] Ophth. Rev., vol. xv, 1896, p. 309.

Binasal and Unilateral Nasal Hemianopsia.—Cases of binasal hemianopsia occur with comparative infrequency. The literature has been analyzed by Veasey,[16] who makes reference to nineteen cases, but who also includes in them cases of unilateral nasal hemianopsia of the bilateral form of the disease as it is seen in spinal cord disease. The subject has also been discussed by S. M. Burnett,[17] who reports a good example of this affection.

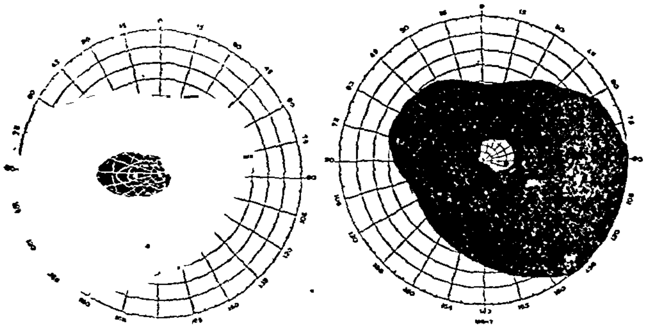

Fig. 8.—So-called binasal hemianopsia in hysteria, really simply an irregular contraction of the visual field. Patient under care of J. K. Mitchell and G. E. de Schweinitz.

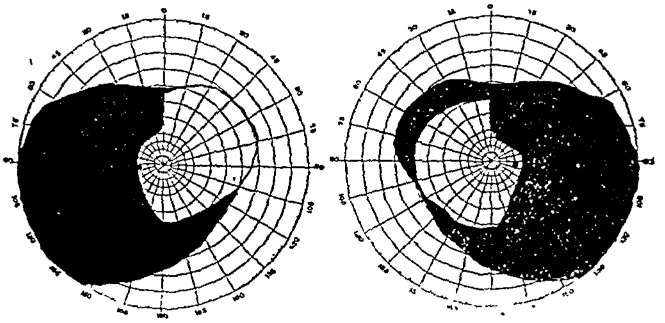

Fig. 9.—Bitemporal visual field defects in locomotor ataxia. Patient under care of G. E. de Schweinitz.

Significance: . The true chiasmal variety of the affection must be rare, if, indeed, it actually occurs. In Knapp's case it was ascribed to degeneration of the arteries of the corpus calosum, causing disease of the lateral angles of the chiasm. Burnett suggests as possible lesions in his case, in which the hemianopsia followed a fall on the forehead and remained unchanged for more than three years, a clot, or pathologic process set up by it, making pressure on the outer side of the right nerve trunk, and passing either above or below this trunk to the other side, without affecting intervening tissue, and there pressing on the temporal side of the left nerve. A double lesion affecting only the temporal supply-fibers in the tracts is also suggested as possible. Burnett himself recognizes, however, the difficulty surrounding the hypothesis he suggests. The irregularity of the remaining fields in most cases of binasal hemianopsia, as well as microscopic examinations which have been made, indicate that visual field phenomena are caused by optic nerve lesions. Thus, Gowers, commenting on Eales's case, suggests as an explanation bilateral inflammation of the trunks of the optic nerves in front of the chiasm, extending to this, and chiefly intense symmetrically at each side of the chiasm. Veasey accepts this explanation as most suited to his case.

A nasal hemianopsia on one side is produced by a lesion affecting the lateral portion of the chiasm involving the non-crossing fibers of one eye. Blindness of one eye and nasal hemianopsia of the other can not be explained by a single lesion. In Henschen's case the chiasm and optic tract were so involved that only the crossed fasciculus of one eye remained comparatively unaffected.

Bilateral Blindness of Chiasmal Origin.—Total loss of vision and of the pupillary reflexes in both eyes, followed in several weeks by bilateral optic nerve atrophy, is possible. Under such conditions we must assume that a lesion has divided the chiasm into an anterior and posterior portion and destroyed the conductivity of the lateral as well as the crossed fasciculi of both sides.

Superior and inferior hemianopsia have been described, and would indicate disease of the upper half of the chiasm, or, as in Uhthoff's case, symmetrical disease of the optic nerves.

OPHTHALMOSCOPIC CHANGES.

Following a destructive lesion affecting the optic chiasm, the ophthalmoscope usually reveals bilateral atrophy from descending degeneration. Partial atrophy of the optic disc results from circumscribed destruction of fasciculi of fibers on their passage through the chiasm. All grades of optic neuritis may be found with disease at the base of the brain involving the optic chiasm, varying from slight veiling of the edges to typical choked disc, but optic neuritis is not often found in chiasmal disease, even when produced by cerebral tumors. A reference to the report of the conditions of the eyegrounds in some fifty cases of disease of the chiasm show the following fundus changes, which can be conveniently grouped:

(*a*) Optic atrophy without preceding neuritis.

(*b*) Postneuritic atrophy.

(*c*) Atrophy of the temporal half of the nerve (partial atrophy).

(*d*) Slight optic neuritis as revealed by blurring of the disc edges.

(*e*) Well-marked optic neuritis and neuroretinitis with or without retinal hemorrhages.

(*f*) "Choked discs."

In one case mentioned by Hutchinson[18], the ophthalmoscope shows retinal arteries and veins diminished, retina white and hazy with many hemorrhages.

---

[15] Just as this section was completed the third volume of Wilbrand and Saenger's "Die Neurologie des Auges," has come to hand, in which there is a most complete discussion of the visual field phenomena which would follow variously placed chiasm lesions.

[16] Ophth. Rec. February, 1897.

[17] Arch. of Ophth., vol. xxix, 1900, p. 1.

[18] Ophth. Review, 1889.

It is important to remember that although central vision in most cases of bitemporal hemianopsia is lowered (rarely normal acuity of sight has been preserved), and that the final stage of chiasmal disease is apt to be total blindness with atrophic discs, occasionally, even after blindness has appeared, as Wilbrand remarks, nearly normal power may return.

ANOMALIES OF THE EXTERNAL OCULAR MUSCLES.

Chiasmal diseases may be accompanied by paralysis of nearly all the motor and sensory nerves of both eyes. The progress of the lesion can at times be closely followed by the successive involvement of the cranial nerves running to the orbit. Anosmia indicates the extension of the lesion forward; bilateral hemianopsia followed by unilateral blindness and paralysis of the cranial nerves entering the orbit of that side shows the extension of the disease toward the right or left side of the chiasm. The third nerve is most frequently affected.

ALTERATIONS IN THE PUPIL REFLEXES WITH SPECIAL REFERENCE TO THE HEMIANOPIC PUPILLARY INACTION.

The production of complete blindness by chiasmal disease gives the usual loss of direct pupil reaction. Most reporters have failed to note the presence of the hemianopic inaction.

In some forty cases referred to by the authors, whose reports we have examined, this inaction was noted in but four cases. The usual note was "pupil dilated and sluggish," or "unresponsive to light, react to convergence."

The hemianopic pupillary inaction has been unquestionably present in some cases and no doubt would have been found if more carefully looked for in many more cases of disease of the optic chiasm. It is a symptom difficult to elicit and its existence has been denied by some authors. Even Bach, with his large experience and skill, has not observed it, although he does not deny that it may occur.

LESIONS WHICH MAY PRODUCE ALTERATIONS IN THE STRUCTURE AND FUNCTION OF THE OPTIC CHIASM.

From a consideration of the anatomic relations of the chiasm, we may divide these lesions as follows:

1. Those which affect the chiasm from below. These include trauma, for example, fractures of the sphenoid bone, exostoses, basilar, gummatous and tubercular meningitis, periostitis, arterial disease, aneurism, syphilitic arteritis and hemorrhage, and tumors of the sphenoid bone.
2. Lesions which encroach on the chiasm from above. These include tumors of the third ventricle and distention of the floor of the third ventricle in internal hydrocephalus.
3. Lesions which affect the posterior angle of the chiasm. These include tumors and hypertrophy of the pituitary body—notably in acromegaly. To this frequent cause of chiasmal disease a more extended reference is made in a succeeding paragraph.
4. The lesions of multiple sclerosis. Cases of this character have been reported by Snell, Taylor, Uhthoff, Spiller and other authors.
5. The lesions of tabes dorsalis. Cases of this character have been reported by Gowers, Uhthoff, Popow, Moxter and Benedict.

The chiasmal symptoms in these cases may be due to syphilitic basilar lesion, and not to interstitial inflammation of the chiasm, as Gowers states. This author also includes as a possible cause of chiasmal disease interstitial inflammation from inherited gout. Interstitial hemorrhage has been reported. Swanzy states that tumors of the cerebellum, by closure of the aqueduct of Sylvius, may produce internal hydrocephalus and cause pressure upon the chiasm.

The above summary comprises the results of careful study of the literature for reports of postmortem findings in somewhat more than one hundred published papers.

ACROMEGALY.

As is well known, acromegaly is a frequent cause of bitemporal hemianopsia, and this visual field defect, to use the language of Swanzy, is one of the commonest and earliest symptoms of this affection. It does not seem necessary to do more than make the briefest reference to the facts in the case. According to Hinsdale, the bitemporal hemianopsia in acromegaly is caused by an overgrowth or neoplasm of the hypophysis pressing on the chiasm, and by bony changes consequent on the abnormal growth of the lesser wing of the sphenoid bone. It may occur as a bilateral defect, as an unilateral defect, either right or left sided, and in two instances, at least, has appeared in the form of a nasal hemianopsia.

While it is true that the bitemporal variety of the visual field defect is the one most commonly observed, homonymous hemianopsia has also been noted by several observers. One of them (de Schweinitz) has examined a case of this character for Dr. Dulles of Philadelphia, and he has also seen and examined two other cases with typical bitemporal hemianopsia, one in the service of Dr. H. C. Wood at the University Hospital and the other in his own practice.

SIMULATION OF CHIASM DISEASE BY OTHER AFFECTIONS.

Hysterical Hemianopsia.—There is much difference of opinion whether hemianopsia ever occurs as an ocular stigma of hysteria. Parinaud maintains that there is one variety of visual insensibility which hysteria appears to be incapable of producing, and that is hemianopsia in the sense in which this term is used in organic cerebral lesions, and this opinion apparently is shared by Charcot, Gilles de la Tourette, Gowers, Freund, Binswanger and others. On the other hand, Rosenthal[19] states that in all cases of hysterical amblyopia which he has investigated temporal hemianopsia was present[20]. Lateral non-crossed hemianopsia in hysteria has been recorded by a number of observers, for example, Bonnefoy, Westphal, Galezowski, M. W. Zimmerman and Henry Lloyd.

So far as we are able to judge from a critical examination of the literature, hemianopsia as an enduring ocular symptom of hysteria does not exist. On the other hand, as a temporary phenomenon it has been observed a good many times by those who are competent to judge, and has appeared, as already noted, as a bitemporal defect, a homonymous lateral defect, and even, it would seem, as a binasal obscuration. It is possible, according to Pierre Janet[21], that there may always be a period of hemianopsia when the ordinary hysterical amaurosis is recovering.

A similar observation was made by Galezowski and Daguenet prior to his publication, who have also noted a transitory scotoma. Hirsh[22] describes hysterical blindness in a boy of thirteen. After return of sight, there was high grade contraction of the visual field, which gradually widened and showed a temporary bitemporal hemianopic character. Unilateral temporal hemianopsia has been described in hysteria by Landesberg[23] Wilfred Harris in his Cambridge Thesis[24] refers to two cases of hysterical binasal hemianopsia, one of temporary character reported by D. B. Lees, the other published by J. K. Mitchell and de Schweinitz. It is true they somewhat incautiously made use of the expression that the visual fields had the character of binasal hemianopsia, but they are quite sure they should be regarded simply as an unusual form of bilateral contraction. (Fig. 8.)

---

[19] Wiener Med. Presse, Nr. 23, 1879, p. 736.

[20] In Gilles de la Tourette's book Rosenthal is quoted as having written a letter to Charcot in which he retracts this statement, saying that hysterics exhibit only amblyopia and concentric contraction of the visual field.

[21] La Presse Medicale, 1899, p. 243.

Bilateral Temporal Field Defects in Locomotor Ataxia.—As Gowers has pointed out, symptoms of a local lesion in the chiasm may occur in rare instances of tabetic atrophy. In one case which he has recorded the characteristic visual defect appeared suddenly. Popow[25] has examined in cases of ataxia the chiasm and found foci of degeneration. But the visual field changes in tabes dorsalis may simulate chiasm disease, when, in all probability, the chiasm itself is unaffected. It is probable that tabetic atrophy of the optic nerve may depend in part on disease and disappearance of the retinal ganglion cells. Should such disappearance occur on suitably situated symmetrical areas, symmetrical temporal field defects might follow. (Fig. 9.) It will be observed in a case which one of us (de Schweinitz) has observed, that although there is a form of bitemporal hemianopsia, the dividing line is irregularly placed and this in all probability would be a notably distinguishing, although not pathognomonic difference between ataxic and the chiasm-disease visual field.

Bilateral Temporal Field Defects in Brain Tumors Unconnected with the Chiasm.—As well recognized causes of bitemporal hemianopsia are basal tumors, and especially tumors of the pituitary body. But it should be remembered that a growth at a distance from the chiasm may occasion similar signs. As Swanzy, Gowers and others point out, a tumor of the cerebellum by closure of the aqueduct of Sylvius may produce internal hydrocephalus and thus exert pressure on the chiasm. So far as we are aware, bitemporal hemianopsia has never been observed as has cortical hemianopsia as a distant symptom. It is possible, however, that destruction of areas of retinal ganglion cells in cases of the choked discs of non-basilar cerebral tumor might give rise to bitemporal binasal visual field defects, but in such a case there would of necessity be marked irregularity in the line dividing the visual fields.

A brief reference to the lesions of the chiasm in multiple sclerosis has been made.

SYMPTOMS OF CHIASM DISEASE CAUSED BY CERTAIN TOXIC AGENTS.

We have already referred to central amblyopia and central scotoma as a sign of chiasm disease, and how such a scotoma may be difficult to distinguish from that produced by toxic amblyopia. One of us (de Schweinitz[26]) has published the results of microscopic examination of the optic nerves, chiasm and tracts from a typical case of so-called tobacco amblyopia with characteristic and intact visual fields. Degenerated patches are evident, occupying symmetrical positions in about the situation of the non-crossing macular fibers and leaving the remainder of the chiasmal structure intact.

Necessarily, they give no evidence of their existence except in the central scotomas. According to Westphal and Elschnig, optic neuritis with bitemporal hemianopsia has been observed as an ocular symptom of lead poisoning.

Homonymous lateral hemianopsia has been occasioned by illuminating gas toxemia, as reported by Purtscher and H. Friedenwald, but not the bitemporal variety of this form of the affection. Raffegean observed in a case of carbonic acid poisoning inferior hemianopsia dependent on a certain degree of interstitial neuritis of the optic nerves.

CONCLUDING REMARKS.

In the presence of typical bilateral hemianopsia, which, as we have before remarked, quoting the words of Griffith, may be regarded as the localizing form of hemianopsia, it is practically impossible to make a mistake, and the lesion must necessarily be, as already stated, one which destroys the conductivity of the crossed fasciculi, leaving the non-crossed fasciculi intact. When one comes to consider, however, the numerous irregularities in the visual field which may be present in chiasm disease, its existence can not always with safety be inferred from them without elaborately repeated examinations.

As Wilbrand has remarked, the chiasm with both tracts and the other intracranial portions of both optic nerves may be surrounded by diseased processes, particularly of a gummatous nature, and irregular defects of the field of vision result, from which a correct diagnosis would be difficult. Much depends on the method of examination and the degree of the destruction of the light sense. A careless examination might fail to develop a temporal field defect which a more careful one, conducted under diminished illumination, or using gray squares placed on white cardboard, would develop. On the other hand, an examination with a very bright light, for example, such as one uses in an electric perimeter, might reveal an intact visual field on the temporal side, good light sense being preserved, while it would be absent for form or colors.

Finally, the fact that a scotoma may be the beginning of a visual-field defect which will eventuate in a bitemporal hemianopsia and be significant of chiasm disease, should not be forgotten, and, moreover, a scotoma which to careless examination would seem to indicate simply papillo-macular bundle involvement and not involvement of the intermingling of the papillo-macular fibers in the chiasm.

The evident conclusion of the whole matter is that, in a large number of cases of optic nerve atrophy, the most elaborate examinations should be made by all known tests, under all degrees of illumination, and with all types of saturated colored squares, in order to eliminate or prove the presence of chiasm disease. We strongly suspect that there are a fair number of optic nerve atrophies on record, and, naturally, a much larger number in examination, which, if these precautions had been observed, would have yielded a larger percentage of chiasm disease than now seems indicated by the reports.

DISCUSSION.

Dr. Casey A. Wood, Chicago, stated that for a number of years he has suspected that those curious cases of aversion to binocular single vision are due to certain congenital defects of development; in other words, to lack of proper crossing of the optic fibers as they run forward from the visual centers. So far as he knows no proof of such an anatomic anomaly has been advanced to explain this failure to obtain binocular single vision. The fact that in certain cases of squint (usually alternating) two eyes with equally good vision, though straightened and treated by every known means, should still object to a completion of the act of binocular single sight is remarkable. It is exasperating that after early operation and training under apparently the most favorable conditions binocular single vision is unobtainable. Dr. Wood has not been able to accept the theory of lack of development of the fusion centers; he believes that we shall find the explanation in lack of proper crossing of the fibers at the chiasm.

Dr. John T. Carpenter, Philadelphia, said that perhaps Dr. Wood's suggestion could best be carried out in a general hospital, where such cases might be followed and autopsies properly made. He thought that the rarity of these cases is shown by the fact that in fourteen years he has not had a case of chiasm disease in his private practice.

Dr. Clarence A. Veasey, Philadelphia, exhibited a skiagraph of a recent case of chiasm disease. The patient is a robust man, perfectly healthy all his life, except for this ocular disease. He has been able most of the time to follow his vocation, that of a traveling salesman. Two years ago this chiasm disease showed itself, beginning in the temporal field of each eye as a slight fogginess. Later the form field was lost, the light sense being retained. The dividing line has varied from time to time. At one time it would pass directly through the fixation point; at another examination it would pass from 2½ to 15 degrees to the right or left of the fixation point; then again through the fixation point. There were no intraocular changes. This variability of the field can only be explained by a lesion, probably vascular, which produces change in the pressure between the examinations.

Dr. J. L. Borsch, Philadelphia, said that it is advisable, even when there is atrophy of the nerve, when destruction of nerve fiber has taken place and the chiasm is separated into an anterior and posterior portion, so to speak, to give a guarded prognosis, for a patient may present an atrophy of the optic nerve and one may be led to believe that permanent blindness has resulted, and still such a patient may recover his vision. Seven years ago Dr. Borsch saw a patient in the de Wecker clinic who had been brought in by a friend, which friend had wrested a revolver from him as he was about to take his life, as several oculists had told him that he was incurably blind; one of these gave him a certificate to that effect in order that he might enter the blind asylum. On examination it was found that he had complete atrophy of both nerves, with slight light perception on left side of field; on close questioning the fact was elicited that during the Franco-Prussian war he acquired lues, which had not been treated; he had had the ordinary diseases of childhood, but otherwise had never been ill, and in other respects was healthy. The man was placed on energetic specific treatment, and at the end of four months he had 1/6 vision, and in six months 2/3 vision. Dr. Borsch saw the patient last year while in Paris; he had normal vision in right eye and 2/3 in left.

Dr. G. A. Aschman, Wheeling, W. Va., mentioned a case seen six years ago of angiolithic sarcoma of the optic chiasm. The patient had a central scotoma which grew from week to week, but before that occurred it was thought to be a case of tobacco amblyopia, as he had been a heavy smoker. The interesting point was that this patient did not have any fundus changes for a long time. There were no signs of pressure; no choked disc. It was thought for a time that it might be a syphilitic trouble, but he did not improve at all on antisyphilitic treatment. It illustrates what has been said about confounding these cases with tobacco amblyopia.

Dr. Flavel B. Tiffany, Kansas City, Mo., said that he had a case a year ago of bitemporal hemianopsia in a man of 50 years of age, who came to him complaining of blindness on the temporal side of each eye. There was no history of syphilis, no trauma. Vision was 20/70 of the right eye and 20/200 of the left. The color sense was also impaired, especially for red. The treatment was pilocarpin ¼ grain twice a day, also vibratory massage once a day. The patient improved on this, his vision coming up to 20/40 and 20/70, respectively, in the two eyes. The etiology was very obscure. The trouble was probably due to a toxemia from grippe, which he had had two months before the onset of the hemianopsia. The lesion was evidently located in the chiasm involving the crossed fibers or those from the nasal side of each retinæ.

Dr. C. R. Holmes, Cincinnati, referred to a case in which the postmortem showed the exact condition afterward. A newspaper reporter came on account of inability to use his eyes. Careful examination revealed the fact that his glasses were correct, and with the ophthalmoscope no lesion was visible. He was ordered on a vacation, but returned worse than before. The condition was rather obscure. He, however, had a good deal of swelling in the nose and complained of inability to breathe. Dr. Holmes operated on one side, removing the hypertrophied tissue, and he was to come the following week for another operation. The day before the second operation was to have been performed Dr. Holmes was notified that he was not well enough to come, and the next day he learned that the patient was dead. He at once sent an assistant to try to secure a postmortem, which he succeeded in getting. It was found that there had been inflammation with necrosis of the sphenoid cavity, which had not been apparent at the examinations through the nose. When the brain was removed there was found a clot in the region of the sella turcica and extending over the chiasm. The bony roof had been entirely eroded, and a finger could be put into the sphenoid cavity.

Dr. John E. Weeks, New York City, asked why we do not more frequently find choked disc in these cases. A compilation has recently been made by one of the physicians associated with the New York Eye and Ear Infirmary of 102 cases,[1] and in only one or two of these cases was choked disc observed. The theory advanced by one writer is that the disease of the chiasm closes the subarachnoid space where the optic nerves leave the chiasm, and that the entrance of the subarachnoid fluid into the subvaginal space of the optic nerve is thus prevented.

Dr. G. E. de Schweinitz particularly called attention to the series of cases described in which there is simulation of chiasm disease by other affections, and particularly to the explanation which they have endeavored to give of so-called bitemporal hemianopsia of hysterical origin, which is never in their experience a permanent stigma of this condition, but which simply represents a form of the well-known amblyopia of hysteria.

THE MATHEMATICAL POINT OF REVERSAL IN SKIASCOPY.*

SWAN M. BURNETT, M.D., Ph.D.
WASHINGTON, D. C.

Of all the objective methods for determining the refractive state of the eye, the shadow test is not only the most reliable, but, up to a certain point, the easiest to apply practically. In view of these facts it seems unaccountable that concerning the laws underlying the method, there should be such a lack of clear and positive proof offered, even by those who are supposed to deal with the subject in an authoritatively scientific manner. The ordinary text-books for students and general practitioners, without exception, I believe, pass over the theoretical part very superficially, giving attention wholly to the signification of shadow movements "with" and "against," mentioning the "point of reversal" only casually, with a matter of course assumption that everybody knows where it is.

---

[1] N. Y. Eye and Ear Infirmary Reports. 1904.

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

It is not my intention to charge these writers with ignorance of the laws on which the phenomena are based, but they certainly lay themselves open to criticism of lack of explicitness by any one seeking for a satisfactory scientific explanation of the fundamental principles involved. I am inclined to think that this lack of precision and definiteness in description may be due, in many cases, to the want of a clear idea of what it is that we really observe in making the examination by this method.

We are aware that Cuignet, who was the discoverer and first employer of the method in a systematic manner, had an entirely erroneous conception of the essential optical principles. He believed that the cornea was the chief agent in causing the phenomena, and since this was the thing to be observed he gave the name "keratoscopy" to his method.

It would seem also that some writers regard the image of the flame giving the illumination formed on the fundus of the observed eye as the object of direct observation, and have thus given some sort of justification for the use of that hybrid abomination "retinoscopy;" and I am sorry to see that Dr. Jackson makes one statement in his article on skiascopy in the Norris and Oliver's system which lends countenance to this. He[1] says: "The movement to be observed is the apparent movement of an area of light on the retina."

Any one reading the context, however, will discover that he does not mean that specifically at all, but something quite different, which only shows how nearly our best men sometimes come to making misleading statements in dealing with this subject.

Others, prominent among whom is Landolt, teach that the object of observation is the pupil, if we may accept the term "koroscopy" as indicative of his idea, though one is left in a confused state of mind as to whether he means the pupil of the observing or of the observed eye.

Now there can be no question that the subject of observation in this method is neither the cornea, the pupil nor the movement of an area of light over the retina. A study of the optices involved shows that it can be only one thing, and that is the image of the bright area on the fundus formed by the refracting system of the eye at the conjugate focus of the retina, or the far point of the observed eye. On this simple and fundamental mathematical fact hangs all the law and the prophets of the skiascopic method. In the higher degrees of myopia this lies between the eyes of the observer and the observed. In hyperopia, it lies behind the observed eye, while in emmetropia and low degrees of myopia it is behind the observer's eye, placed at the ordinary observing distance. The optical laws, explanatory of all the phenomena involved on this basis, I have exposed in a previous article[2] on this subject, and to this I refer those who care to examine into the details of the exposition.

In returning, at this time, to the "point of reversal," it is to attempt to clear away some obscurities that have surrounded its location and established its exact position in the quite complex optical system of which it forms a part.

In practice, it may suffice to say, in a general way, that the eye of the observer is at the point of reversal, but in any discussion of the question in an academic manner, as should be the case when we are dealing with an exact science like optics, it is necessary to establish that point with mathematical precision.

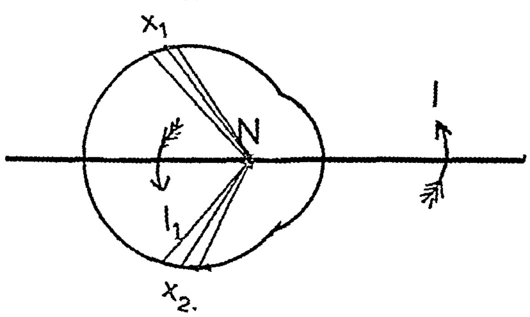
As in optics we deal entirely with points and lines, there must be a mathematical point in the compound optical system to which it belongs where the movement of this image in one direction passes over to that in another. Where is that point? The answer should be simple and clear.

Now we know in order to have a movement against the mirror rotation, an inverted image of the bright spot on the fundus of the observed eye must be formed in front of the nodal point of the observing eye, while in order that there be a movement with the mirror rotation, an exact image must be formed behind the nodal point of the observing eye; it necessarily follows, therefore, *that the point of reversal from the one to the other is the nodal point itself.*

This is shown in Fig. 1, where all movements of the image I, in front of the nodal point N, are against the mirror rotation, while all movements behind N, as at I^1, are with the mirror rotation. At N itself, which is the point of transition, or reversal from one movement to the other, there is no movement at all.

Furthermore, it must be apparent that when the image of the bright spot lies at N the rays X_1 and X_2 preceding from any one point of it divergently in all directions, as they do from every illuminated object, are sufficient to fill the whole of the interior of the eye, since they are not acted on by any refracting medium. It follows, then, that so long as there is a single point of the image remaining at N, under a rotation of the mirror in any direction, so long will there be a steady and full illumination of the field with no defined edge, shadowy or otherwise.

Fig. I.



The point of reversal at the nodal point, therefore, is characterized by no movement and a steady illumination under all mirror rotations. Moreover, these phenomena are possible only when the image of the bright spot lies exactly at the nodal point.

This is so inevitable that it seems strange that it has not found a categorical expression before this, but I have not been able to find it.

An explanation of the confusion and lack of clear expression on the subject may be found in one of several causes. The principal one, as I have mentioned previously, seems to me to be the want of a definite conception as to what is really to be observed and the position it occupies respecting the observing eye. Jackson, to whom we are so much indebted for his careful studies of the optics involved, fails to bring his usual clearness of demonstration to bear on this explanation, and the average student would not, I fear, find his ideas as to the exact point of reversal altogether free from confusion, for the reason that he leaves so much to be inferred.

---

[1] Vol. II, p. 91.

[2] Am. Jour. of Ophth., May and June, 1903; and in the "Principles of Refraction," published by the Keystone, Philadelphia, Pa., 1904.

The same must be said of the account given by Souter, who has written lucidly and comprehendingly on optical questions in general.

Neither is Tscherning any more satisfactory in what he offers either as to the principles of the method or the point of reversal in particular. Accepting the theories of Parent and Leroy, he attaches great importance to the rôle of the pupil, and fails to mention the nodal point at all in this connection.

He says, in speaking of the point of reversal on page 210 of his "Physiological Optics": "At the critical moment, when the light changes its direction, the far point of the eye coincides with the pupil of the observer." Landolt in his last treatise on the methods of determining the refraction of the eye, now in course of publication in the new edition of the Gräfe-Saemisch System, *takes the positive stand that the point of reversal lies* in the pupil of the observer's eye. He says on page 248: "Aside from those conditions in which the illumination of the pupil with the mirror, be it plane or concave, moves in the same direction and those in which it moves in the opposite direction, there is yet another in which no movement of the eye is perceived at all, because the pupil in its entirety appears either illuminated or dark. This occurs when the far point, that is, the conjugate focus of the retina of the observed eye falls *in the pupil of the observer's eye.*"

We have shown above that the conditions of constant illumination and no movement to which he alludes has its mathematical explanation only in the coincidence of the image of the bright area on the fundus of the observed eye with the nodal point of the observer's eye. It is possible to conceive here that the pupil, as such, can play a necessary part in the production of either of these phenomena; yet Landolt, throughout the text of his treatise and by the illustrations and diagrams, insists that it is the pupillary edge of the iris which plays the principal rôle. In this he has evidently followed Wolff, the latest German authority on skiascopy, from whom he quotes largely.

That the diaphragm of the ophthalmoscopic mirror with its sight hole, can and does play a modifying part in the sequence of appearances, can not be gainsaid and in my article, above referred to, this has been given due attention and what is there said can be applied with equal pertinency to the iris and its pupillary opening. It was there demonstrated and shown by diagrams, how when the examination was made in the usual way, and the point of reversal was at the nodal point of the observing eye, the pupillary edge of the iris of the observed eye, had its conjugate focus and image on the retina of the observing eye. This, however, is a secondary incident and has no direct nor necessary connection with the main and essential feature of the position of the point of reversal. If there were no iris nor diaphragm of any kind, the mathematical principles being still the same, the point of reversal would yet lie at the nodal point.

The iris and its pupillary opening not being in any sense cardinal points in the complex optical system, it is difficult to understand how it came about that such high authorities came to select this location as the point of reversal, except as an approximate guess.

It is true that in the normal eye the nodal point is not far removed from the pupillary opening, but in aphakia, for example, it is some distance behind, being at the center of the corneal curvature. There seems no more reason then, from a strictly mathematical point of view, for selecting the pupil as the point of reversal than the apex of the cornea or any other point in the immediate vicinity.

It has to be conceded that in our crude method of examination we are not able to locate the point of reversal with the mathematical exactness here insisted on. There is always a limited space within which the movements are not clearly defined, so that the phenomenon does not offer an immediate passing over from one movement to the opposite.

This inaccuracy can usually be neglected as insignificant in low degrees of ametropia, and when the point of reversal is located at a considerable distance from the eye, that is, one meter or more. Moreover, it must be held in mind that for the perfect working out of the law it is necessary that all points of the image fall on the plane coincident with the nodal point. Should the image be not so formed, some points being in front of, and some behind the nodal point, there will be conflicting shadows within the illuminated area. These I have called "internal shadows."[1] They have their origin in irregularities in the refracting media and are usually most pronounced under a wide pupil, which exposes the irregular astigmia of the periphery of the refracting media, particularly that of the cornea. In some cases these are sufficient to materially vitiate the findings. *For the most accurate results this method demands media clear of any irregularity in refraction within the area of the pupillary opening.*

DISCUSSION.

DR. EDWARD JACKSON, Denver, stated that any one who has followed the demonstration can see that it is the nodal point of the eye and not the pupil at which reversal takes place. In the sense in which Dr. Burnett speaks, of course, one does not look at the light area on the retina of the observed eye, but at the image of that retina which is formed at the conjugate focus of the retina on which the light area is situated; in the same sense, with a pair of opera glasses or field glasses one does not look at the actor or at the landscape, but at an image formed by the glass. One looks at the object through the intervention of the image. A paper of this sort can perhaps be better appreciated when read than when listened to, but it is of great practical importance to frequently follow these mathematical problems through a clear demonstration in this way. Not that it is the best way to learn the facts, perhaps, but that it is a good way to get a working conception of the facts. These facts can be learned from a book, but to follow them through a demonstration of this kind gives a working knowledge that is of great value, particularly regarding the shadow test. Nothing else in ophthalmology has been done so much by rule of thumb.

DR. MARK D. STEVENSON, Akron, Ohio, said that the mathematical point of reversal is never found in actual practice, and can only be imagined in theory in an ideal or standard eye. The light reflected from the fundus of the patient's eye passes out and forms an area of light at the examiner's face. If this area is much larger than the examiner's pupil only a certain amount of the light enters his pupil and the portion of the patient's pupil through which these rays pass, alone, appears illuminated. The remainder of the patient's pupil appears slightly darker. If all the rays of light reflected from the patient's fundus would focus at or pass into the observer's pupil, he would receive rays of light through every part of the patient's pupil which would appear completely illuminated. This will place him at the practical point of reversal. If the examiner could dilate his pupil *ad libitum*, so as to make

---

1. Trans. Amer. Oph. Soc., 1892.

it correspond to the area of light on his face, the patient's pupil would always appear fully illuminated. It is thus seen that if the observer's pupil receives all the rays of light, the observer is at the practical point of reversal. However, in this ideal condition under consideration, we must imagine a perfect anterior focal point or point of reversal coinciding with a pin-point pupil. The secondary rays of light will necessarily cross one another at this perfect focus, through this pin-point-sized pupil, thus making the nodal points coincide to the location of the pupil and point of reversal. Mathematically they do coincide, although in practice the pupil is the determining factor.

DR. SWAN M. BURNETT declared that it must be apparent that there can be only one mathematical point of reversal and that it is the nodal point of the examiner's eye.

SYPHILOMA OF THE CILIARY BODY.[*]

HERMAN KNAPP,
NEW YORK CITY.

My interest in cases reported by Dr. Charles J. Kipp,[1] Newark, N. J., and Dr. Edward Stieren,[2] Pittsburg, Pa., and in a recent case of my own, leads me to give a general description of this peculiar and uncommon condition.[3]

Dr. Kipp's first case was seen May 14, 1903. The right eye was normal, V. = 6/5. The left eye was greatly inflamed; conjunctiva intensely congested and slightly swollen; lids normal. Anterior chamber of normal dimensions, the temporal half filled with fibrinoid exudation. The nasal half of the iris visible, swollen and discolored. Pupil closed. No pain. The eye had been red and painful five days before Dr. Kipp saw the patient. Patient denied syphilis.

Diagnosis.—Irido-cyclitis plastica.

Treatment.—Warm fomentations, atropin instillations, sodium salicylate, leeches.

Five days later there was some bulging of the sclera along the upper and outer border of the cornea. This bulging increased, and two days later a dark-colored spot the size of a pinhead was noticed in the outer part of the horizontal meridian. Eye T + 1, intensely painful. Another black spot, smaller than the first, was noticed near the former; both grew larger. The bulging of the sclera increased, and some blood added itself to the yellowish mass in the anterior chamber. Dr. Kipp, believing that he had to deal with an intraocular growth, enucleated the eye. The wound healed in a few days. Shortly afterward Dr. Kipp learned that his patient had been treated energetically for syphilis.

Pathology.—Examination by Dr. Alt showed a mass of soft tissue, which had broken from inside through the sclerotic near the cornea, on the upper and outer side. The tissue was in direct communication with the enormously swollen ciliary body. The tumor started in the pars nonplicata, proliferated in the pars plicata and absorbed the iris. The optic nerve was atrophic. The tumor consisted altogether of small, round, polymorphonuclear cells, mostly mononuclear.

After-Treatment.—After the operation the patient received mercurial treatment and had good health.

Dr. Kipp's second case, a man aged 44, was brought by his physician. He was under treatment for syphilis. The left eye was normal, the right deeply injected, but not chemotic. Cornea hazy, Descemet's membrane dotted with whitish particles, the iris discolored and swollen, pupil contracted, secluded. Good perception of light. Mercurial treatment to be continued. He reported twice more, at intervals of a month. The eye went from bad to worse—hypopyon, iris covered with a thick, yellowish exudation, intense congestion of the entire globe with chemosis, cornea hazy, anterior chamber obliterated, pupil closed, faint perception of light, T + 2. In the sclera, a few millimeters from the outer margin of the cornea, several small black nodules projected 1 mm. above the sclera. Dr. Kipp yielded to the entreaties of the patient and enucleated the globe.

Examination of Tumor.—The tumor occupied the site of the ciliary body. The iris was drawn into the channel of the perforation. The ciliary body opposite the tumor was atrophied, but covered by tumor tissue, implicating the iris and filling the whole anterior chamber. The tumor broke not only outward, but also through the pigment epithelial layers of the pars plicata into the eyeball. It consisted of closely packed small mononuclear and polynuclear cells, and was in places quite vascular.

The patient recovered his health under prolonged treatment.

My own case is as follows:

A frail, unmarried woman of 32, consulted me Nov. 16, 1903. She is pale and has not been well for some time. Five days previous to her coming she found that her left eye was blurred. S. 20/70. In the center of the posterior surface of the cornea was a cluster of fine dots. Fundus blurred, but free from inflammatory foci. F. and T. normal. I made the diagnosis uveitis serosa, ordered rest in bed, atropin and salicylate of soda.

November 21. V.=20/40—. As the salicylate disagreed with her, I ordered calomel, refracta dosi. November 27. V. fallen to 5/200. Then she told me that she had syphilis and had been under treatment for it. I advised her to go to the hospital. She accepted at once and stayed there[4] seven and one-half weeks, where I saw her every day.

Treatment.—She was kept in bed as much as she could stand and was treated with mercurials, chiefly inunctions, and instillations of atropin and sublamin to keep the conjunctiva free from irritation. She developed an intense iridocyclitis. The ciliary region in the upper temporal part began to swell, at first in shape of a white, vascular nodule, which soon burst and showed the black uveal pigment. The swelling extended along the upper and outer neighborhood of the corneal margin. Its elevation was 3 to 4 mm., its length 6 to 8 mm. The cornea was hazy, the iris vascular and lack-luster, the pupil was about 3 mm. in diameter, its edge beset with filiform synechiæ. Tension increased, therefore instillation of 1 per cent. eserin, which soon reduced the hypertension. Yet it returned again when atropin was used, which was continued to reduce the iritis and prevent the closure of the pupil. Codein was given with the atropin. For a week her sight was more than perception of light, which as well as the projection, was always good. This kept me from proposing enucleation to her, though I asked myself whether that would not be the best treatment. Considering, however, that recovery of useful sight can never absolutely be denied, as long as perception of light or projection are preserved, I continued the treatment, and was gratified in seeing that gradually the symptoms abated. She never had great pain, for whenever it set in with plus tension, we gave her a myotic and morphin. As soon as tension was reduced we used homatropin or atropin, watching the effect.

December 12, about six weeks after her admission to the hospital, she counted fingers at 1 to 2 feet. The hypertension not infrequently alternated with hypotony, so that we could give atropin without hesitation. She was discharged Jan. 24, 1904. Pupil irregular, clearer; T. fundus dull; F. contracted temporally; V. fingers at 12 feet. The conjunctival congestion had almost disappeared, the perforation in the sclerotic was circumscribed, the elevation of the sclerotic diminished. She received strychnia tablets, gr. 1/50 for a week, then she was treated with potassium iodid and mercury mixed.

Result.—Her recovery progressed steadily. Atropin produced no glaucomatous attacks any more. The cornea and iris cleared themselves, the anterior chamber remained shallow for weeks, the pupil dilated, the filiform synechiæ did not entirely disappear. March 29, with + T. 21/50, fundus still hazy. April 5, no inflammation, interior normal, pupil somewhat oblong. April 23, 1904, interior clear, some synechiæ; V. with — 1C. 90° 20/20.*

[3] I acknowledge suggestions from the excellent monograph of Prof. T. v. Ervetzky, Ueber das Syphilom des Ciliarkörpess, Berlin, 1904.

[4] N. Y. Ophthalmic and Aural Institute.

Thus the patient and the physician could mutually congratulate themselves on the reward of their perseverance.

Dr. Edward Stieren's case of gumma of the ciliary body was as follows:

A woman of 21, family history negative, was married at 16 years of age, gave birth to a living healthy child ten months after marriage. Six months later, November, 1899, symptoms of secondary and tertiary syphilis appeared (sore throat and abscess of tongue; a month later small brown blotches over the whole body, etc.). She nursed her child, contrary to advice, and infected it, but the child was soon cured by mixed treatment. The mother, receiving the same treatment, in appropriately larger doses, until March, 1900, when, against advice, she ceased medication. Dec. 24, 1900, she reappeared with a deep, spreading ulcer of the right side of the nose, involving the cartilaginous septum and the upper lip. She was put on large, rapidly increasing doses of potassium iodid, and in a week returned with the ocular involvement. The eye was extremely intolerant of light, with intense ciliary injection, muddy iris, cloudy aqueous, large leucocytic hypopyon, and a small inactive pupil.

Treatment.—Hot fomentations, instillation of atropin, large doses of potassium iodid, with ⅛ gr. of calomel every two hours, every day until Jan. 4, 1901, i. e., twelve days, when salivation called for the withdrawal of the mercury. On this date the eye presented the following condition: Hypopyon absorbed, pupil fully dilated, photophobia, ciliary injection and tenderness on pressure marked. Two days later a purplish diameter, gradually spreading in every direction, very painful to the touch. The pupil contracted opposite the swelling, giving it a kidney shape. Acute and constant pain, ciliary injection reaching its height, sight reduced to perception of light. Cornea very hazy in twenty-four hours, almost no fundus reflex.

January 10. Swelling increased, with oblique light; it was dimly seen to extend into the vitreous, pushing lens and iris forward. T. + slight. One hundred grains of potassium iodid were taken three times daily.

January 12. Patient more comfortable; photophobia and tumor unchanged; 160 grains of potassium iodid t. i. d., well tolerated.

January 16. Anterior chamber obliterated, showing reflex from vitreous chamber T. — 2; 180 grains potassium iodid t. i. d.

January 19. Total paralysis of rectus externus; 200 grains potassium iodid t. i. d.

January 29. Eye improved; pupil well dilated except at gumma; no synechiæ; the scleral aspect of the tumor slate-colored; fundus reflex bright, but no details of background; gumma notably smaller inside and out. V. 3/200; T. — 1; left external rectus regaining strength. From this date on steady improvement, reducing potassium iodid to 160 grains t. i. d.

April 6. The large doses of potassium iodid were no longer tolerated; now gr. x were given three times daily. Gumma had entirely disappeared, pigmentation in sclerotic marks its site. V. = 6/40.

May 1. Background clear, showing the remains of a neuroretinitis.

July 19, 1901. Perfect movement in all directions; a slight accommodative squint relieved by a cycloplegic. The round pupil slightly up and nasal. V. with correction, R. 6/8, L. 6/6.

Dr. Stieren draws the following conclusions: Syphilitic gummata of the ciliary body or of any other structure of the eye need not call for a hopeless prognosis, even though vision be reduced to perception of light and eyeball tension materially reduced. The resolution of gummous neoplasms is best brought about by large and rapidly increasing doses of the iodids; no limit in dosage need be thought of; the drug must be pushed until the symptoms yield, the gummy tumor melts away, exudates absorb, and inflammation subsides.

I indorse these views, except that in primary syphilis mercury would be my choice. As proof I cite my case in which the disease was identical with that of Dr. Stieren's in the pathologic conditions of the eye and in which the mercurial treatment brought about a perfect recovery.

GENERAL NOTES OF THE SYPHILOMA OF THE CILIARY BODY.

Occurrence.—The beginning of this affection is difficult to determine, on account of the locality which we can not see. It seems usually to originate in the plicate part of the ciliary body as a nodule which, under inflammatory symptoms, grows in every direction, mostly into and through the sclerotic, into the anterior chamber, and into the vitreous at the relative frequence of 16:17:1, according to Ewetzky's statistics of 67 cases. Mostly it encroaches on two or even three parts. Usually only a single tumor develops, rarely (13 per cent.) two. More than two in one eye have not been noticed.

Appearance.—In the sclera it first appears as a small nodule, which may increase to the size of a bean. In its growth it is surrounded by a ring-shaped elevation, steep toward the cornea, but gradual toward the sclerotic. It is yellowish gray, and black when it has perforated the sclerotic.

In the extreme cases phthisis bulbi is the end. All intermediate grades up to perfect restoration are represented.

The duration of the disease varies from two or three weeks to nine or twelve months.

CONCLUSIONS.

The first appearance of the syphiloma frequently is a small nodule in the iris-angle of the anterior chamber, from whence it takes its way outward through the sclerotic or into the anterior and vitreous chambers, with exudations in the former as hypopyon spurium.

Only 9 per cent of Ewetzky's series had been free from iritis. The pupil is mostly changed by posterior synechiæ of the iris and membranous exudations, preventing more or less the examination of the posterior parts of the eye. These are frequently more or less seriously affected; for instance with congestion of the retina, retinitis in white patches, and postneuritic atrophy of the optic disc.

The shape and mobility of the globe are damaged in many ways and degrees.

As to sex, there were 47 men against 215 women; 52 per cent. were between 20 and 30 years old; 28 per cent. ended in phthisis bulbi. In 30 per cent. the enucleation was made.

The acuteness of sight in Ewetzky's count was in 66 eyes:

Blindness		63.6 per cent.
Weak sight	S=0.1	13.6 per cent.
Moderate sight	S=0.1 S=0.3	12.6 per cent.
Good sight	S=0.7 S=1.0	10.6 per cent.

Dr. Stieren's and my cases *fortunately* increase the good results.

---

*Note on correcting the proof, Dec. 5, 1904: The patient reported from time to time, continued to take small doses of KI, has had no relapse, and has perfectly recovered. The perforation of the sclerotic is still indicated by a small black patch. No changes in eye. Tn, Fn, V 20/20. H. K.

DISCUSSION.

DR. SWAN M. BURNETT, Washington, D. C., said that syphilis of the eye is not usually a particularly malignant affection in the negro, but when the ciliary body becomes involved he has never yet been able to stay the process sufficiently to restore vision to any serviceable degree. Some years ago he reported in *Knapp's Archives* some cases of this sort with a drawing made from a section of the ball. A peculiarity of the structure, as these revealed, is its close pathologic resemblance to tubercle. The giant cells are pronounced in their formation and structure. Another point in which it resembles tubercle is that it destroys the tissue in which it is embedded. Last winter Dr. Burnett had a case under observation which under vigorous treatment finally disappeared, but the whole of the ciliary body and iris were transformed into cicatricial tissue, and he is sure that it will soon be added to the collection of eyes lost by syphiloma of the ciliary body. One of the most marked symptoms is the intense pain which it causes. It is essentially a secondary manifestation. Dr. Burnett has a man under observation now presenting a perfectly typical appearance who is in the secondary stage of the disease. The protuberance from the ciliary region is 5 mm. It is the second case he has seen this year. The treatment should be as vigorous as possible. Formerly he gave deep muscular injections of bichlorid. This is painful and it is difficult to get the patient to submit. Where he can not do this he uses the inunction treatment. He does not have to enucleate all these eyes, but he has a larger collection of them than he takes pride in. Dr. Burnett said he would like to hear from his confrères in the regions where the negro abounds regarding the frequency of this disease and its malignancy.

DR. CHARLES J. KIPP, Newark, N. J., said that he has not seen a case in which it did not become necessary to enucleate in the end. Cases in which there is apparently syphiloma of the ciliary body can not be diagnosed with certainty unless the tumor perforates the sclera. Dr. Kipp agreed with Dr. Knapp that mercury is preferable to the iodid. A patient came to him after the tumor had appeared on the outside of the sclera and was rapidly spreading. The man denied syphilis, and it was thought to be some form of intraocular tumor. There was a grayish-yellow exudate in the anterior chamber, covering the iris. It was only after the tumor began to spread that it was found to be a malignant tumor. The man returned two months after enucleation of the eye and said that he was getting blind in the other eye. There was a mild ciliary injection and some spots on Descemet's membrane. He was at once put on inunctions of mercury, and in eight weeks this eye was all right. A similar process was undoubtedly starting in the other eye. Dr. Kipp now relies entirely on mercury in these cases.

DR. E. E. HOLT, Portland, Me., stated that, during the Spanish-American war, there were a good many of the soldiers in the Maine Eye and Ear Infirmary, and in one there was a marked case of this kind, the left eye being the one involved. The inflammatory process came through the ciliary region and burst. Dr. Holt did not remove the eye, and the right eye was not involved at this time. The inflammation subsided. Within a week or ten days, however, the right eye presented a tumor in the ciliary region which went on and burst, and that eye was lost. Dr. Holt asked Dr. Knapp if removal of the first eye would have prevented the occurrence of the inflammation in the other.

DR. SAMUEL L. LEDBETTER, Birmingham, Ala., said that nearly all negroes have syphilis and they are generally neglected, so that this is a common sequence in that race. They generally do not appear for treatment until the sclera has ruptured and so, of course, a large percentage of the eyes are lost. A certain number can be saved when they come for treatment early enough.

DR. ROBERT L. RANDOLPH, Baltimore, said that he had recently observed a case which, in its objective signs, was like that described by Dr. Burnett. The patient was a white man and had been under the care of an ophthalmologist who had expressed the opinion that the condition was sarcoma of the iris and that the eye would have to be enucleated at once. There were, however, several things about the condition which led Dr. Randolph to think it was a case of luetic infection, and he put him on large doses of iodid of potash and also gave mercurial inunctions. In six weeks the man had recovered. While it is unlikely that the eye will ever become a useful organ, it is at least a comely and a harmless one.

DR. HERMAN KNAPP said that in syphilis the nodule which first appears soon disappears and the part above swells and almost invariably bursts and there is a black excrescence, which is pigment from the ciliary body. That is not characteristic in sarcoma, where the nodule is more or less oblong and tongue-like and in which there are very few inflammatory symptoms. This, Dr. Knapp thinks, is sufficient to make the differential diagnosis between this condition and sarcoma of the iris or ciliary body. Dr. Knapp, in replying to a question, said that he does not believe that sympathetic action in the other eye ever acts in that way, so that the removal of the eye would probably make no difference.

TEMPORAL CLEFT OF THE NERVE HEAD.*

CHARLES H. BEARD.

CHICAGO.

Having used the ophthalmoscope rather industriously in large eye clinics and in private practice for the past twenty-one years, I have been strongly impressed by the oft-repeated occurrence of a certain aberrant picture of the optic nerve entrance. Roughly estimated, the total number of well-marked examples of such anomalous optic papillæ that I have encountered is about sixty—seen in the eyes of perhaps forty individuals—or about one in every 1,000 persons.

This I consider an extremely conservative estimate, as I believe the number to be greater.

The most distinctive feature of the appearance in question is an apparent wide parting in the optic nerve fibers at the temporal side, or a sort of triangular cleft, outward, of the cortical portion of the nerve head. Briefly described, the condition and accompanying phenomena manifest the following peculiarities: The gray pink color of the disc is confined to a crescent at the nasal side which, with its horns, occupies about two-thirds of the circumference of the scleral ring. This crescent, at its broadest part, would seem to be somewhat wider than the normal zone of nerve fibers. The scleral and choroidal rings, as far as they outline the crescent, are of nearly normal width and appearance—probably a trifle narrow. Outward. the scleral ring is broad and slanting and, in most instances, the choroidal ring becomes a small external conus. Indeed, the cleft would seem to be nearly related to external conus, and does not occur with conus up and down or annular. I have seen a few such clefts where no conus existed. The whole disc is slightly foreshortened, owing to the obliquity at which the nerve pierces the sclera and the trunks of the retinal vessels appear suddenly from behind the horns of the gray-pink crescent. The triangular segment of the disc bounded by the horns, and the external scleral ring is on a lower level and is glistening white, excepting next to the scleral ring, where a blue-green shadow marks the brink of the depression. The depth of the depression is not great—hardly so great as that of an ordinary physiologic excavation—and is seldom crossed by any save the tiniest of the retinal blood vessels. Now and then a vessel from the posterior ciliary system, or circle of Zinn, is seen to traverse this area—a truly unique sight in ophthalmology. All of which goes to prove that there are few nerve fibers between the observer and the sclera in this locality.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

There are never any openings of the lamina cribrosa visible in this area, not even in its nasal extremity or apex. The diameter of the scleral ring is not excessive—on the contrary, in a few instances, the papilla is abnormally small—it and the adjoining conus both taken together not appearing larger than an average disc. From the beginning, the picture here presented has suggested to me that of a flower of the morning-glory family, projecting into the fundus, from the nasal side viewed in a horizontal manner, and with its stem hidden behind the globe. So I have come to note it in my records as "morning-glory right," or "left," or "both," as the case may be. In at least one-half the cases the anomaly is bilateral. Twice I have seen it in the eyes of more than one child of the same parents.

Anomalies of the retina (*a*); of the choroid (*b*); of the refraction (*c*) are constantly associated with this cleft optic nerve.

(A) ANOMALIES OF THE RETINA.

Those referable to the retina include freakishness in the distribution and other characteristics of the vessels. Often a posterior ciliary artery comes in and plays the rôle of a good-sized retinal one. Frequently, one of the eight larger vessel trunks is wanting, and the lack is made good by one from the opposite side, taking on twice its usual size and sending over a branch to supply the need. To judge from the shape and dimensions of the carefully mapped out blind spot in these cases, there is also an unnatural arrangement and distribution of the macular bundles of nerve fibers in the retina. This spot is almost invariably elongated toward the center of vision and that, to a degree and with a configuration out of all keeping with the size and form of any conus that may be present. Without the data of an exact anatomic examination of such a retina, to guide in the matter, a logical explanation of this peculiarity of the blind spot would seem to lie in the wide separation of the macular fibers. In other words, to the actual absence of the triangular sector of macular fibers at the optic-nerve entrance, and which corresponds approximately, in shape and size, to the cleft under discussion.

ANOMALIES OF THE CHOROID.

Among the anomalies of the choroid that exist in this connection, the most conspicuous and constant is the appearance of general lack of development. This tunic is thin and barren, being specially poor in capillaries and pigment. Hence, the eyeground is streaked [illegible] nd the irregular distribution of the pig- [illegible] the characteristic peppered look com- [illegible] as "powder-grain fundus." In rare [illegible] es a plaque at the posterior pole, [illegible] wherein the choroid is either com- [illegible] has undergone pigment degenera- [illegible] oidal coloboma of the macula. [illegible] ted spots in the periphery are [illegible] nally there exists that condition [illegible] s the [illegible] undus tigré.

[illegible] F REFRACTION.

[illegible] under consideration, while [illegible] from the normal, is [illegible] acceptation of the term. Low grades of myopia and myopic astigmatism are the prevailing errors, though moderate degrees of hyperopia and hyperopic astigmatism are not uncommon among them. I have never seen this cleft associated with a high refractive error. Where the nerve defect is monolateral there is apt to be anisometropia or antimetropia. Temporal cleft of the nerve head with external clonus is not to be confounded with the obliquely set disc associated with posterior staphyloma, absorption of the choroid and high myopia. I do not remember ever to have seen the cleft in conjunction with these. In uncomplicated cases the defect or anomaly does not extend beyond the nerve head itself. The visual acuity, notwithstanding the best correcting lenses, is often below the standard, owing to the scant choroid. The fields of vision show varying degrees of diminished peripheral light sense, up to troublesome hemeralopia, but no other marked anomalies aside from those relative to the *punctum cœcum* already mentioned.

One of my cases was that of a 33-year-old man who came with the statement that since earliest childhood he had been unable to see at night, and that he had two brothers who had the same affliction. I rather expected to find the ophthalmic picture of retinitis pigmentosa. It proved to be a typical, double temporal cleft of the nerve head with the tiger fundus.

Another singular feature, that characterizes nearly every case, is torsion of all the fundus details toward the temple. Disc, conus, retinal vessels, fovea and macular coloboma of the choroid (when one exists) all show this temporal twist. This may have some reference to the fetal rotation of the globe, first noted by Kolliker,[1] and later by Vassius[2] and by Vasseaux.[3] This, of course, causes the macula and fovea to be placed abnormally low.

Cases complicated by great defects of the choroid are apt to have nystagmus and strabismus, particularly of the divergent variety. I have not seen any, however, that were accompanied by microphthalmos, harelip, cleft palate, nor other evidence of an imperfectly closed fetal fissure.

No inconsiderable amount has been written on the coloboma of the optic nerve and of the optic-nerve entrance. They mostly refer to incomplete closure of the ocular fissure, and are in conjunction with the downward coloboma of the choroid. The rest has to do, mainly, with various ectasias of the scleral portion of the nervehead, taking the forms of deep cavities or pits, single or multiple, within the area of the papilla, and situated at indiscriminate places. Another class, also quite prevalent in text-books and atlases, refers to a broad and deep excavation at the site of the optic-nerve entrance, whose dimensions, always considerably greater than that of the former disc, are often many times larger. The cases here in point are not those of true coloboma of the optic nerve, but their occurrence would seem to answer more to the explanation given by Ginsberg, of anomalous optic entrances which he had studied, both in the eyes of man and the lower animals. viz., a defect of the lamina cribrosa. A blocking up of the openings of the lamina cribrosa at the temporal side, or perhaps in some cases, an external, triangular area in this locality, where the sclera is actually imperforate. This would account for the crescentic arrangement of the optic nerve fibers, for the absence of any visible scleral perforations serving for the ingress of the nerve fiber bundles, and, in part, for the characteristic findings of the blind spot.

[2] Arch. f. Ophth., vol. xxix, p. 119.

[3] Arch. d'Opht., vol. xiii, p. 523.

The nearest approaches to the description of the particular cleft of the nerve head treated of herein that I have found in the literature, are those of de Wecker, Stood, Nuël and Elschnig, though none of them conforms precisely to it. The nearest approximation as regards the papilla alone is the case of Nuël, but here there existed also high myopia and a plaque of bared sclera, outward, several times the size of the normal disc. Taking it all in all, Elschnig's case, which he examined anatomically as well as ophthalmoscopically, tallies most closely, though the ophthalmoscopic findings were considerably at variance with the cases here cited. Stood's second case is, to a degree, along this line, but here the temporal cleft was incomplete, as regarded the optic-nerve fibers, and a deep pit of ectasia occupied its floor and into which two retinal vessels dipped and disappeared, to emerge again on the other side.

Fuchs refers to a singular anomaly of the papilla, consisting in the presence of a small, temporal conus, and a white membrane covering the vessels over the greater part of the disc. He had seen three cases and cites another of Hirschberg.

I take it that the conditions presented by the fundi now brought to your notice have an important pathologic significance. This relates mainly to the accompanying imperfections of the choroid, as exemplified in its limited capillary system, its irregular pigmentation, diminution of the peripheral light sense, and general lack of blood supply. Its early recognition might redound to the great benefit of the possessor of such a fundus, for by one might hope for the possible prevention or amelioration of diseases arising through slow sclerosis of the choroidal vessels and other degenerative changes in the choroid, such as glaucoma simplex, true inflammatory glaucoma with high intraocular tension, and grave secondary degeneration of the retina. This would be accompanied, of course, by proper attention to the general physical condition, to the correction of errors of refraction, and, most important of all, to the regulation of the eye work in general.

DISCUSSION.

Dr. G. E. de Schweinitz, Philadelphia, said that when one examines the fundus of the eye with the aid of Dr. Beard's intelligent observations, one becomes familiar with appearances which, while they may have been seen before, were never properly appreciated or interpreted. Dr. de Schweinitz considers that the temporal cleft of the nervehead, which Dr. Beard has called the "morning glory," should be called "Beard's nervehead." In some recent investigations Dr. de Schweinitz has been struck with the frequency of various anomalies, in the nervehead, of the retinal circulation and of the fundus of the eye generally in the so-called degenerate types. This has recently been the subject of an important series of observations in France, and the conclusion has been reached that there is nothing in the eye itself, so far as functional examination reveals, indicative of the degenerate type. Dr. de Schweinitz does not believe, however, that the end of this matter is yet at hand and thinks that the subject demands more elaborate investigation. If Dr. Beard's investigations are correct, we should all endeavor to recognize the conditions which he has described, because they may give indications for treatment which will prevent later ocular calamities.

Dr. Edward J. Brown, Minneapolis, said that during the past year and a half he has carefully examined all refraction cases with reference to the ophthalmoscopic appearance of the disc. Of the first 160 cases 39 presented greater or less temporal concavity of the disc, not confined to the center, and of these 3 or 4 presented the appearance described by Dr. Beard in sufficient degree to attract attention, 2 of them being decidedly pronounced. Of the 39 cases only 4 had perfect fields, the others presenting peripheral defects ranging from 10 to 30 degrees. Dr. Brown's attention was especially called to these cases by the paper published by Professor Schoen of Leipzig in the *Ophthalmic Record* of October, 1902, presenting evidence that the so-called "physiologic excavation" of the optic disc is pathologic in character. Dr. Brown's observations suggest that concavity of the disc, not confined to the center, may at least indicate that such eyes belong to a class especially liable to be the subjects of glaucoma.

Dr. Charles H. Beard, in replying to a question, stated that he had never found this cleft in conjunction with any fissures or openings indicative of imperfect closure of fetal clefts. With colobomata involving the nervehead one often sees microphthalmos and other deformities. The nearest he has found with these are nystagmus and strabismus. Where anisometropia exists, as Dr. de Schweinitz suggests, it is the eye that has the cleft which has the higher degrees of refractive error, i. e., where the defect is monolateral. At a joint meeting of the Chicago Ophthalmological and Chicago Medical societies, Dr. Beard in April last brought out the point in connection with the "powder grain" fundus and thin attenuated choroid; these cases are particularly liable to have wide physiologic excavations. In all those cases there is diminished peripheral light sense, and they are truly pathologic cases. Dr. Beard has found that these cases average up intellectually as well as any he has ever seen.

DEVELOPMENT OF THE FACULTY OF BINOCULAR FUSION.*

EDWARD JACKSON, M.D.
DENVER.

The fusion faculty, which controls the ocular movements in the interest of binocular vision, is one of the most delicate and exact, yet one of the most constant and rigid co-ordinations that the human being acquires. That it is not commonly possessed at birth seems to be well established by the agreement of all careful observers. That it is normally developed in early childhood, and only during early childhood, is equally certain. Persistent intelligent efforts have failed to give any indication of its acquirement in adult life. I believe it is well established generally before the age of 2 years, and practically always before 6. The earlier age is that of normal development; the later is the limit of delayed or obstructed development, beyond which its appearance or development is impossible.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

Although development of the fusion faculty occurs after birth, it is, I believe, determined essentially by congenital tendency. It is a race characteristic, and is not a result of the reaction of the individual to environment. It develops, as do the sex characteristics and organs, in obedience to inherited impulse; not like the power of reading or writing through conscious effort or training. There is not very much evidence on this point, yet what there is is fairly conclusive.

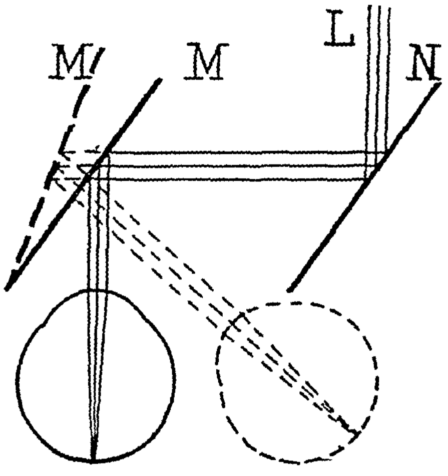
Take, for instance, the case reported by J. L. Minor to the American Ophthalmological Society in 1898, of a man operated on for congenital cataract at the age of 40. After one cataract had been removed the patient was still able to judge distance better with both eyes shut than he could by the sight of one eye. The other cataract was removed, and ten days later, when he was first allowed to use the two eyes together, tests with prisms and stereoscopic figures showed complete binocular vision. Two days after that when his eyes were again unbandaged he could judge distance accurately with both eyes open, but he usually missed when either was closed. His power of overcoming prisms was still comparatively feeble.

The very rapid acquirement of the power of binocular fusion from a few brief lessons with the amblyoscope reported by Worth and others, and which I also have witnessed, seems inexplicable except on the supposition that the fusion faculty has spontaneously become well-developed, although the patient, on account of some obstacle, has never learned to control or use it. Thus in the first of Worth's illustrative cases "fusion training" was given on five different days within a period of two weeks. On the fourth occasion it is noted: "The child as considerable amplitude of fusion." After the fifth ance, the eyes remain straight with glasses. Where the fusion sense has been established and the squint continues, Worth speaks of the repetition of fusion training once a month as being quite sufficient to keep up the fusion faculty until operation is permitted.

Evidently our most advanced treatment of squint today simply removes obstacles such as inequality of vision in the two eyes, or errors of refraction and the abnormal innervation they entail, or demonstrates to the child the existence of the fusion faculty that has already developed. But there are rare cases in which, without any apparent obstacle, no trace of binocular fusion seems to develop. In these cases without any serious error in refraction, with perfect vision in each eye, and no deviation of the visual axes, there still exists independence of function in the two eyes. They have no power of stereoscopic vision and no binocular diplopia can be provoked. There are also cases of alternating squint which are precisely similar to the [illegible]e, except that the movements of the two eyes are [illegible]inated to excessive convergence or divergence. [illegible] still larger class of cases a feeble faculty of binocular [illegible]sion or some rudiment of such a faculty is dis[illegible]t it is not capable of overcoming even slight [illegible] he bulk of uncured convergent, like the [illegible] ivergent squints of Worth, belong to this [illegible] o [illegible] ement of those cases must lie our [illegible] dded future success in the treat[illegible] w have instruments, the amblyo[illegible] d the stereoscope, with which the existence of the fusion faculty when it has already developed, but which he has heretofore left unused. These instruments, however, are not adapted to help in the continuous exercise of a fusion faculty which beside being unused, is really undeveloped.

In seeking an instrument that would aid us in the actual development of the fusion faculty, I have worked out one by which the patient can employ his binocular vision, such as he may possess, not only on a few specially prepared objects or slides, but on all objects that he looks at and continuously, even while there remains actual squint of any degree. The matter can be best presented by an explanation of the instrument.

In viewing the reflection of objects in a mirror there appears a lateral reversal of relative positions. If this reflection is reflected from another mirror the second reversal gives the objects their normal relative position. If the two mirrors are parallel, each object seen is seen after double reflection in its true direction. By inclining the surfaces of the mirrors to a certain angle each object seen through them appears displaced to double that angle. When, as in squint, the visual axis of the fixing eye is directed toward one point, that of the deviating eye is directed toward another. But by causing one or both eyes to look at such double reflections as are furnished by plane mirrors inclined to the proper angle it is easy to present the same object to the visual axis of both the squinting and the fixing eye. The accompanying diagram illustrates the effect of changing the direction of one of the mirrors.



The solid lines represent the mirrors M and N as parallel and the eye as receiving the ray L parallel to its original direction. The broken lines represent M inclined as for a convergent squint, the altered direction of the ray after its second reflection, and the way it would be received by the converging eye. By varying the angle of the mirror M, the reflected ray can be given any direction required for even the highest degree of squint.

The instrument can be used for the same purposes as the amblyoscope or an adjustable stereoscope, with slides prepared as for the stereoscope. But it can also be used in looking at any object near or distant, to produce any modification of direction required in the interest of binocular fusion. If there be present a rudiment of this faculty, even with a high degree of squint, the mirror can be set at such an angle as to constantly stimulate the exercise of fusion. By varying the inclination of the mirror M, the patient can be induced to increase or diminish his convergence, and thus exercise his power of maintaining fusion.

For an instrument not to be worn by the patient the before one eye only, the other being left free as in ordinary vision. The instrument swings either way on the upright that supports it so, that it can be used equally well for the right or the left eye. The arc can be graduated to show just how much convergence and divergence the position of the mirror represents. The reflection from two mirrors somewhat lessens the visibility of objects viewed by means of them; hence, the mirrors should ordinarily be placed before the non-deviating eye. To bring down the vision to an equality with that of the deviating eye, a series of smoked glasses of different shades are also furnished. These can be slipped in front of the opening, in the clip for this purpose.

With the width between the eyes, the degree of squint, and the difference in visual acuteness exactly known we can, in any given case, construct a binocular instrument very much smaller than this, which can be attached to a head band and worn continuously. With such an apparatus all the child's seeing for hours, or throughout the day, should be done under conditions that bring the two images of a given point on corresponding points of the two retinas.

I believe that with such an application of this principle of double reflection we will be able to bring about the development of fusion faculty in some cases in which such development would not otherwise occur. With the fusion faculty once fairly developed the complete cure of comitant squint becomes possible.

DISCUSSION.

Dr. Wendell Reber, Philadelphia, declared that there are three essentially different methods of regarding the eye: First, as an optical instrument contrived to form a perfect image, every focal point of which shall correspond with a radiant point in the object viewed; second, the retinal structure, and especially its bacillary layer; third, the still more wonderful correspondence of the two retinas, point for point, and of their representatives in space, point for point. Dr. Reber said that in the study of methods for the training of the fusion faculty, the question of the evolution of binocular vision is the primary consideration. It is a bewildering complex coordination, gradually acquired like walking or talking. The most rational method of studying this subject would seem to be in adults who, because of complete congenital cataract, have grown to maturity without seeing, and then had both eyes successfully operated on. Several such cases have been reported from time to time. One case recorded by Trombetta four or five years ago was that of a girl of 10 years, who had both eyes successfully operated on by Guaita, the eminent Italian ophthalmologist. Trombetta took charge of the young girl and in 45 lessons he succeeded not only in teaching the child to see without the sense of touch, but in obtaining satisfactory binocular vision. Before the twenty-fifth lesson, when the child's attention was directed to a nearly bright object, one eye would fix and the other wander up and out and oscillate. In the course of this lesson it was discovered that the child's vision had become stereoscopic. Dr. Reber said that in the case of the 40-year-old man quoted by Dr. Jackson, the question arises whether some sort of crude binocular vision did not develop and flourish before the man became entirely blind from the congenital cataract. If so, it would, of course, be a relatively easy matter for him to regain the faculty of stereoscopic vision when both retinas had been restored to their functions. This rousing of the faculty of attention and its close relation to the act of convergence, Dr. Reber considers, is closely bound up with the development of binocular vision. Le Conte shows that perception of the third dimension proceeds largely from an almost imperceptibly rapid exercise of the faculty of convergence. This fact, along with the psychologist's "mental faculty of attention," seems to form the basis for correct visual judgments. Whether the complex array of acts in binocular vision are or are not represented in the cerebral cortex by a special center is still *sub judice*. That a fusion faculty exists is beyond all doubt. Functional strabismus shows that the higher centers have abandoned the task of making the retinas correspond point for point, and must, therefore, be viewed as a species of atavism. The small globes and short interocular base line in little children, assisted by the excessive accommodation, will account for the turning in of the eyes rather than the turning out as would be expected. In constructing mechanical devices for the training of the fusion faculty one thing is axiomatic: that is, they should be simple and, if possible, so devised that they may be used several hours each day. The instrument here offered by Dr. Jackson is beautifully simple and if, as he states, it can be made small enough to be worn with a headband for several hours a day, it would seem to approach very closely to the ideal device for the development or restoration of stereoscopic vision. Priestley Smith's fusion tubes, one of which the child would take in each hand, represents the acme of simplicity. But as the child's visual axes are crossed, the tubes got in each other's way, and Mr. Worth happily thought of the reflecting tube and built his amblyoscope which has proved so efficient in selected cases. At no time should apparent parallelism of the visual axis be accepted as proof positive that the patient has been restored to stereoscopic vision. Some test for stereoscopic vision should invariably be resorted to as a final test, such as Hering's box, which is easily made and is quite as reliable as any.

Dr. Edward Jackson stated that the case cited by Dr. Reber is certainly nearer the experience of most cases of the sort that have been reported than is Minor's case. His case is a very exceptional one in the rapidity with which binocular vision was demonstrated after the second eye had been operated on. It was a remarkable patient; a patient who had remarkable powers of co-ordination for an absolutely blind person. The best illustration we have that binocular vision is developed sufficiently to go right into use after some obstacle is removed is the vision that children often get after the correction of a high error of refraction. Many of them will quickly or in a few days respond to the tests of full binocular vision. That is the basis for the assumption that binocular vision may develop to a high degree without having been exercised. The obstacle being removed binocular vision becomes possible. While the child undoubtedly acquires something in this short time, it does not acquire the complete nerve connections necessary for binocular vision. There is something there ready to be used as soon as the child acquires the knack.

DAIRY HYGIENE.

WITH SPECIAL REFERENCE TO THE LIMITATION OF BOVINE TUBERCULOSIS.*

RICHARD COLE NEWTON, M.D.
MONTCLAIR, N. J.

While perhaps it is impossible to be absolutely sure of the truth of any general statement, of which from its nature complete proof is unobtainable, we are justified, I think, in assuming that the statement that wild cattle are entirely free from tuberculosis is true. We are told that the native (Criollo) cattle of the Argentine are now and always have been free from tuberculosis. The appearance of the disease dates from the time when pure-blooded cattle were introduced into that country for breeding purposes. So it has been asserted that the native cattle of the Jura mountains and other places are, and always have been free from tuberculosis. So far as known, no animal running wild and eating the food that nature intended, has ever been tuberculous; and yet the disease is to-day the most common and most generally distributed of all diseases, affecting as it does, all living creatures, including man and every known species of warm-blooded animal, as well as fishes, amphibians, birds and reptiles.

---

* Read in the Section on Hygiene and Sanitary Science of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

Since the discovery of the tubercle bacillus in 1882, there has been a steady advance in knowledge of this disease, and of its, hitherto unsuspected, distribution throughout the animal kingdom.

There is, however, no proof that an animal living as nature intended, as has just been said, will ever become tuberculous;[1] while on the other hand, it seems to have been distinctly proved that under appropriate conditions, with a large enough dose of the infecting material, any living creature may be made tuberculous. Coincidentally with the knowledge of the great distribution of tuberculosis, has come the welcome knowledge that the disease is, to a great extent, curable in both man and animals.

It was a revelation to pathologists when Trudeau and others observed that if rabbits were inoculated with tuberculosis and then allowed to run at large, they recovered, while those kept in confinement after the inoculation died. So a small number of successful experiments have been reported undertaken to show the curability of the disease in dairy cattle, notably some at the Storrs experimental station some years ago. Also certain experiments have been made to demonstrate that the susceptibility of cattle to the infection of this disease varies with their environment.

Dr. Pearson of Philadelphia, fitted up two cow stables in the University Veterinary School. One stable had only 3,000 cubic feet of air space and few windows, and was in every way unhygienic. The other had 9,000 cubic feet of air space, plenty of light, and was kept scrupulously clean. Into each of these stables he put four healthy cows and two tuberculous ones, and kept them there for seven months, at the end of which time the four originally healthy cows in the unhygienic stable were affected with advanced tuberculosis, whereas of the four non-tuberculous cattle kept in the hygienic stable only two were tuberculous, and that to an inconsiderable extent.

Dr. de Schweinitz[2] gives a case as follows: "An animal originally tuberculous, kept at the station of the Bureau of Animal Industry, has received about 3,000 c.c. tuberculin in different injections extending over a long time. The animal is now well and fat and has entirely recovered from tuberculosis."

Dr. Salmon stated[3] in 1901 that 20 per cent. of Canadian pure-bred cattle offered for importation into this country were tuberculous, whereas of those brought into the United States for grazing and feeding, not over 0.2 of 1 per cent. are tuberculous, while the milch cattle of ordinary breeds offered for import, occupy an intermediate position. Bang long ago pointed out that the calves of tubercular cows did not themselves become tubercular if immediately separated from their dams and all other tuberculous cattle, and fed on sterilized milk. Theobald Smith, Bang and others have insisted on the desirability of preventing tuberculous infection in dairy herds by keeping the cattle in the open air as much as possible, and keeping the number of cattle in one herd as small as possible.

Conn[4] says: "The fact is that the more experience accumulates the more we learn that many of these incipient cases of tuberculosis are only temporary and that the animals in question, if kept in a favorable condition, will soon recover and may live many years of useful life."

C. S. Phelps, the agriculturist of the Storrs Experiment Station, gives the history of an experiment as follows: "Four cows, having been found to be tubercular, were placed in a high, light and airy stable, affording about 1,500 cubic feet of air space to each cow, and having a yard in which the cattle could exercise. In mild weather they occupied the yard most of the day. No especial treatment for the disease was attempted, but good care and feed were afforded at all times. In October, 1896, all four cows responded to the tuberculin test as they did in January, 1897. In April, 1897, two responded; in July, 1897, none of them responded, nor did any of them respond in December, 1898, a year and a half afterward. In the following February two of the cows were in good, and two in fair health, judging from their appearance. One of them, however, was still coughing."

While the number of observations on the curability of tuberculosis in cattle is quite limited, there seems to be no doubt that the disease is curable as well as preventable in cattle as well as in man.

Nocard has said[5] that animal tuberculosis is now rare in Paris because the animals are not kept longer than a year before fattening and slaughtering. Such a plan would probably eradicate the disease in any country, although all housed and confined animals are sufferers from this disease.

Dr. Louis Robinson[6] pointed out some years ago the greatly superior health of animals in a traveling menagerie over those in zoological gardens, who were confined in one spot, although the latter enjoy every care and attention that science can suggest.

The enormous distribution of tuberculosis in so many different species of animals, fishes and reptiles, would seem to establish the fact that it is essentially the same disease in all, and that the structural, morphologic and pathogenic differences noted in the tubercle bacilli of fishes, birds and mammals are gradually developed and due to differences in pabulum, temperature and environment, which the bacillus experiences in being passed through various hosts.

The ingenious theory advocated by Hueppe and others that the timothy hay bacillus, which has been proved to have slight pathogenicity, is the father of all the different varieties of tubercle bacilli, is not entirely lacking in verisimiltude.

Avian, human and bovine tubercle bacilli can certainly be so altered by cultivation and by passing through appropriate animals that they become indistinguishable. It is not my purpose to discuss this aspect of the subject further, nor is it necessary to burden this paper with figures to prove the enormous distribution of tuberculous disease in dairy cattle.

Experienced dairymen place the percentage of tuberculous cows in New Jersey, for instance, at thirty, and probably the number is about the same throughout the New England and middle states, although, until proper laws are passed enforcing regular stated inspections of all dairy cattle, and the rigid enforcement of the tuberculin test, no really accurate figures can be published. nor can proper steps be taken to eradicate the disease. We are at present only dallying with this very

serious question. To be sure, if no milk from tuberculous cattle was allowed to be sold, there would be now and for a long time to come a milk famine; as there seems to be little doubt that at least one-third of all the milk sold in our markets comes from tuberculous cattle.

It is a saying among dairymen that a tuberculous cow will give more milk than a non-tuberculous one. Whether this is true or not, as we have just seen, it is the pure-bred, high-grade milch cattle that are at present most affected with the disease, and there is not lacking good authority for the statement that superlactation is one of the predisposing causes, if not the principal one, of bovine tuberculosis.

From what has been said, it is evident that it is not alone necessary to destroy, or at least separate, all tuberculous cattle from healthy cattle, but that it is also necessary to take the best possible care of all dairy animals if the disease is to be eradicated and kept out of dairy herds in the future. The proper construction of cow stables and the care and food of the herd have been well understood for some years, but it is not so generally understood that cattle, like human beings, suffer from overcrowding and from confinement. Not over forty or fifty cows should live in one stable, and they should have their regular exercise, even in the coldest weather. The sun should shine into their stables all day long and the cubic air space should be much greater than that usually allowed. Alvord[7] advises 1,200 cubic feet per cow.

One writer,[8] after asserting that the tuberculosis of milch cattle is due chiefly to over-milking, urges that every one should be prohibited by law from milking a cow during the last three months of gestation. Nelson says that if animals are properly cared for they will not contract tuberculosis even when exposed to the disease. He refers more particularly to the diet in this connection.

Fortunately we have an efficient and easily applied means for the demonstration of the presence of tuberculosis in man and animals; namely the tuberculin test. Unfortunately, however, this test is not absolutely infallible in the most scientific hands, and as usually applied, it is subject to certain errors which should be more generally understood and guarded against. That cattle with advanced tuberculosis fail to re-act to the test is well known, but in most, if not all of these, careful physical examination will reveal the presence of the disease. It is in the early stages of the infection, when physical examination fails to reveal anything wrong with the cow, that the tuberculin test is our sole reliance and in these cases, errors, if they do occur, are more likely to be costly and far-reaching. It is asserted by some that a healthy cow may re-act to the tuberculin test. At all events she would unquestionably do so if by any chance the amount injected were too large or too concentrated. Nelson[9] only claims for the test 90 per cent. of efficiency after excluding all sources of error.

Nevertheless, it is a remarkably accurate and trustworthy method of diagnosing incipient tuberculosis, and the failures to re-act when tuberculosis is present, are astonishingly few, when we consider that there is nothing absolute in medicine and that in practically no case can every possible source of error be eliminated.

It is now customary to say that there must be a rise of 2 F. in the cow's temperature within from twelve to twenty-four hours after the injection of the tuberculin to indicate a positive reaction. The bovine temperature, however, is a variable matter, each particular cow being a law unto herself. The temperature during the rut runs higher than at other times. Young cattle as a rule have a higher temperature than older ones, and the temperature of the same animal (without discoverable cause) may vary within considerable limits (Nelson[10] says 2 degrees) on different days and at different hours of the day. While the average dairy cow's temperature may range between 101 and 103 F., it seems unjustifiable to say that a temperature of 103 or 103.5 F. is always due to the reaction from tuberculin. For this reason the temperature of cows should be taken more than the two or three times at two-hour intervals, as is now customary before the tuberculin test is applied. In fact, to render the test fairly accurate, the temperature of each cow should be taken at two-hour intervals for forty-eight hours before and for twenty-four hours after the injection of the tuberculin. As the temperature of milch cattle is variable, and is especially so among Jerseys and other high grade stock, we should expect that their temperature would bear some relation to that of the surrounding atmosphere, and sometimes at least, this would seem to be the case. At all events, Dr. North, of the Purity Milk Farms in Trenton, observed that after thirty-five cows were injected with a double dose of tuberculin in October last, they averaged 1 F reduction of temperature. At the time of the tuberculin injections the thermometer in the barn registered 80 F. The next day there had been a drop of 30 F. in the outside temperature, so that the thermometer in the barn registered 50 F., and every individual cow showed a reduction in temperature of from half a degree to a degree from the evening temperature of the day before, when the tuberculin test was administered. Some of the cattle showed very little variation, so that it may be suspected that they were tuberculous, and had it not been for the great fall in the external temperature, their bodily heat would have increased instead of remaining nearly stationary, after the injection of tuberculin.

A cattle dealer has asserted that he can make any cow pass the test for tuberculosis by putting her in the cold room of a refrigerating establishment and keeping her there a few hours after she has been injected with the tuberculin. The dealer asserted that this keeping of the temperature down could also be accomplished by throwing cold water on the animal with a hose. At all events, for a pronounced case of tuberculosis, or for an animal that has been a short time before subjected to the test, the 2 F. rise which has been agreed on by the veterinarians as the standard, is too high, since, as we have seen, some cattle, although strongly infected with the disease, will not re-act to that extent.

Thirty-eight cows which had passed the state veterinarian of New Jersey and had their papers, were one month afterward re-tested, nine of them, or nearly a quarter, reacted to the tuberculin test. The official tests have been found so often unreliable that many dairy men no longer trust them, but have their own veterinarian test every new cow before she is admitted to the herd. A friend of mine tested twelve cattle in one herd of nice looking, fat cattle presenting no evidence of disease, except that some of them coughed a little, and found that eleven of them were tuberculous. This same man was offered six Jersey cattle, all of which, when tested, showed tuberculosis. These same cows were subsequently sold to a wealthy man from New York for the especial nourishment of his children and invalid mother-in-law.

[7] Year Book, U. S. Dept. Agriculture, 1894.

[8] N. Y. Medical Record, Nov. 6, 1897, p. 685.

[9] Bulletin 118, N. J. Agricultural Experiment Station, Nov. 30, 1896.

[10] Report Biological Dept. N. J. Agriculture College Experiment Station for 1894.

In another case, the one cow picked out of a herd for the exclusive nourishment of a particular infant, was tuberculous. A man went to a farm to buy four cows. The owner agreed to allow them to undergo the tuberculin test as a preliminary to the sale, provided that he should not be told if any of them were tuberculous. On applying the test, three reacted.

In a well-known dairy herd in New Jersey of 350 cows, a careful test is made of each animal every six months, and 15 per cent. of the cows have been repeatedly found to be tuberculous and have been taken out of the herd. Every precaution is observed in this excellent dairy to keep the cattle healthy and eliminate every possible source of infection, with one glaring inconsistency, as follows—the dry cows are boarded at the neighboring farms until they are ready to calve, when they are brought back to the dairy, and some of them must needs bring a fresh infection of tuberculosis with them.

It would probably be as economical to slaughter every cow when she goes dry, according to the method said to be in vogue in Paris, as to lose a third of a valuable herd every year from tuberculosis, and perpetuate the infection.

Nor does careful testing always avail to detect tuberculosis in cattle, nor to prevent its spread, as the following well authenticated case will show: A dairyman, desiring to move a herd of twenty cows from New Jersey into Pennsylvania, had them tested for tuberculosis in compliance with the law. Seven reacted and had to remain in New Jersey. Of the remaining thirteen, four were purchased and put with a healthy herd of 100 cows. In three months' time this herd was tested and only one cow reacted. This cow was one of the four that had been taken out of the infected herd. As the latter herd had been tested by a competent and honest veterinarian, this result shows one of the limitations of the tuberculin test, and it also shows that had the owner of the larger herd not been unusually vigilant he would presently have had, instead of one tuberculous cow, a badly infected herd.

As said before, our present laws are quite inadequate for the eradication of this widespread and rapidly growing infection. The different states demand that cattle brought across their borders shall pass the test, but they do nothing effective to quench the fire which is consuming the very vitals of the dairy industry.

A law commanding the firemen to direct all their attention to the environment of a burning building, but not to touch the building itself, unless they shall receive a request from the owner to do so, would hardly be considered sound legislation, nor calculated to deal effectively with the situation. Yet this is practically the nature of the present laws against bovine tuberculosis. An owner may have his herd tested by a more or less competent veterinarian if he chooses, and may receive about one-half the value for the cattle that are condemned to be slaughtered, or he may, if he elects, remain in blissful ignorance of the real state of health prevalent in his herd and may maintain a hot bed of infection and disseminate tubercle bacilli among the unsuspecting populace indefinitely.

We can no longer screen ourselves behind Koch's fallacious, albeit comforting, pronunciamento that bovine tuberculosis is not communicable to man. That it is communicable has been proved beyond all reasonable doubt. And furthermore, to quote Dr. Salmon,[11] the infection of human beings with bovine tuberculosis is one, if not the principal, cause of the long-continued virulence of human tuberculosis. He says "The human (tubercle) bacilli are generally much more saprophytic in their characters and far less virulent than those of most other mammalian sources, and it seems that the human organism has the power of attenuating these bacilli and gradually making them less and less harmful. But this influence for good must be continually counteracted by the infusion of extremely pathogenic germs from animal sources."

What then is our duty in the premises? It seems to me that there can be no doubt in any thinking mind, that a law should be passed making a semi-annual test of every dairy animal in the United States compulsory, and providing for the slaughter of every one showing any evidence of tuberculosis, and providing further that the owner shall be compensated to the full extent of the damage done him by slaughtering his animal or animals.

Such a movement would not cost a tithe of the sum which the government expects to spend on the Panama Canal, nor of that which it will cost a private corporation to tunnel the Hudson and East rivers in New York harbor, and yet it seems to me that from economic, scientific and philanthropic considerations, the stamping out of bovine tuberculosis would be a thousand-fold more beneficial to our country and to mankind the world over than the consummation of either of the great enterprises just spoken of.

Let us wake up from our lethargy and show that we are really advancing in civilization by adopting a very plain and obvious means of wresting from the "great white death" one of his most powerful and insidious weapons.

Let us also put out of business the bologna sausage man, who gives the dairyman $15 for the carcass of every diseased animal, which the latter can no longer milk at a profit, and makes the meat up into sausage.

Whether or not the remarkable freedom of the Hebrews from tuberculosis is due to eating Kosher meat, the reasonableness of the proposition that we should adopt similar precautions in choosing the meat for our tables is irrefutable in my opinion.

DISCUSSION.

Dr. H. M. Bracken, Minneapolis, approved of testing dairy herds for the purpose of securing non-tuberculous cattle. The percentage of milch cows affected with tuberculosis as given seems very high, and, for Minnesota, he is sure it is too high. He does not think that the passing of a law by Congress compelling an examination of all cows is practicable. Compensation for the cattle destroyed can be easily regulated through the state legislature. In Minnesota a law has been in force for several years allowing compensation. The farmers throughout the state are not compelled to have their cows tested, but many of them are doing so. At first the compensation was two-thirds of the appraised value. The farmers and the dairymen were both well satisfied with this, for, as a matter of fact, the appraisals were generally high, and two-thirds of the appraised value nearly or quite represented the real value of the animal. Later this law was changed, and the owner now receives three-fourths of the appraised valuation. A man may require the testing of cows as a condition of purchase, but the owner is allowed to keep those condemned cows and sell them later in the open market. This should not be permitted. A great deal of the testing of cattle for the purpose of excluding tubercular milk from the city supply is a farce. For example: The dairyman's herd is inspected, say, once a year; 10 cows out of his herd are condemned, and he buys 10 cows to take their places. The 10 cows bought come from the open market, and nobody knows until possibly the next year whether they are tubercular or not. Such methods do not exclude tubercular cattle from the herd. An effort was made in Minnesota to require dairymen to purchase only tested cattle. Of course this is easily carried out in dairies furnishing certified milk, but with the general dairymen it is a difficult matter. Dairymen said they were willing to purchase such animals if they could, and were willing to pay an additional sum for them, but there were no such animals on the market. On various occasions efforts were made to place tested cows on the market, but without success. Dr. Bracken said that while tuberculous milk is dangerous, the dangers may be exaggerated. More children die from the use of bad milk than from the use of tubercular milk, and too often in the effort to secure milk from a non-tuberculous herd of cows the general sanitary conditions surrounding the cow and the milk are entirely overlooked. There is room for the general improvement of the sanitary conditions surrounding the dairy, the cow and the dairyman.

---

[11] Maryland Medical Journal, February, 1904, p. 92.

DR. GEORGE A. HARE, Tacoma Park, Wash., confessed to some disappointment in learning of the status of dairy inspection, and of the sanitary conditions surrounding the dairy supplies given to the people of the eastern states He believes that there are very few questions before the American people to-day fraught with the possibilities for good or evil to such an extent as is the question of dairy products and their proper inspection and believes also that we are looking entirely in the wrong direction for help. He said that the remedy is at our hands and just as soon as the medical profession wakes up just so soon will this question be solved in a practical manner. This question will be finally settled by the verdict of public opinion and public opinion on sanitary matters is molded almost entirely by the attitude of the medical profession. With a careless or indifferent family physician we can not expect very much care on the part of the recipient of the dairy products. If the physicians are asleep and apathetic on this vital question, the people will remain so. In the eastern states tubercular cattle are far more numerous than in the West, where the cattle have larger ranges. About 3 per cent. of the cattle tested in California are affected with tubercular disease. The sanitary affairs of every state at the present time are supervised by a board of health. The time has come in our country when these boards of health should be controlled by physicians Where they are controlled by physicians there is no good reason why the standard of dairy products may not be raised and maintained at any degree of efficiency the physicians choose. Dr. Hare said he had observed the conditions in a small city of 20,000, which a few years ago had no sanitary regulations. A board of health of five physicians was appointed, all of them untried men, but they had enthusiasm and a confident faith in the practical results of properly enforced sanitary laws. The result is that every dairy in that county is at the present time required to operate under a license. In the application for license it is specifically stated that the vendor of milk will subscribe to and observe every condition laid down by the board of health, and those conditions are printed in the application, with the statement that if he violates them wilfully his license will be forfeited If he violates them unconsciously he agrees to correct the error immediately on his attention being called to the matter. As a result of these methods that city has clean dairies —the dirty ones went out of business. They raised the price of milk a trifle, not nearly so much, however, as the gain in the prevention of the use of water. Every dairy is inspected every month. Every dairyman is under contract not to purchase milk outside of the product of his own cows, nor outside of the cows registered by the inspectors, and never to sell milk from any cow that has not been tested. When he adds a new cow to his herd, that cow must be tested, or his license is forfeited. The milk dispensed in the summer time must show below 50,000 bacteria to each c.c. In the winter season the bacteria must be below 30,000 to each c.c. The count is made twice each month, and with but one exception has been below the requirement and down even as low as 10,000 or 12,000 for a number of months. Those are practical results. Dr. Hare could see no reason why it should not be within the province of the medical societies of this country to so supervise the dairies of America as to exclude all diseased cattle, and to demand that all cows must be properly inspected. Public sentiment so strongly endorses the work of the board of health of that city that no dairyman in the county at the present time wishes to risk a lawsuit. Every dairyman's report is published in the paper. This has greatly stimulated the dairies to compete with one another in the production of a good product, because the people will go to the dairyman who has the best record. They find it to their own interest to watch one another. Until physicians realize that they can control the dairy business of this country they will be unable to control tubercular cattle.

DR. HURTY asked how long this process has been in existence and for how long a period the health officer is appointed.

DR. HARE, replying to these questions, said that this process has been in existence for three years, and that the health officer is appointed by the board and continues in office at the pleasure of the board. The board is appointed by the mayor for a period of four years, but the physicians took a hand in the framing of the charter, which specifically states that not more than two persons of the same political party can be members of the board of health.

DR. J. N. HURTY, Indianapolis, said that he became very much discouraged at one time in the work of controlling the milk supply on account of an experience at Indianapolis. They had an excellent health officer. He was doing good work. He had been in office for two years, that being the term of the mayor; then the politics of the city turned over, and out he went. Fortunately, another good man was put in, and he continued the work which the first man had inaugurated, producing very excellent results: then the politics of the city turned back again, and out he went. Dr. Hurty thinks that boards of health should not be composed of physicians entirely, and it would be well to have trained sanitarians on them. In the State Industrial University, situated at Lafayette, there is a department of hygiene. The man at the head of the department is not a physician; he is a graduate of the Boston School of Technology and has had training with the Massachusetts Board of Health. He has brought the department up to a high degree of efficiency, and, although not a physician, has been very successful in teaching sanitary science and this fact has led Dr. Hurty to believe that if a professional sanitarian, although not a physician, is appointed to the board, good results would be produced. The gentleman has been permitted to work through several administrations at Lafayette, no matter whether democratic or republican, because he is not a physician but a professional sanitarian. Dr. Hurty believes that there was a health officer at Mont Clare who was not a physician. He was very efficient and did good work there, and is now employed by the United States Geological Bureau in the hydrographic department. This promotion came on account of efficiency. In Indianapolis a plan was tried of managing the dairies that was extra-legislative. At that time there was no milk ordinance. The secretary of the board of health enlisted the aid of the newspapers and the board announced, although there was no law for it then, that they would give licenses to all dairymen whose dairies would pass inspection and the newspapers printed the rules as to what would be required in the inspection. The people were very much interested, and the dairymen all rushed in to get their licenses, because the people demanded it. The plan worked well. The state veterinarian tested the cattle. Photographs of clean dairies appeared in the newspapers from time to time, and the very best results were being secured; then out went the man. Politics interfered, and the work has to be done all over again at some future time.

Surgeon-General Sternberg, Washington, D. C., agreed with Dr. Hurty that a professional sanitarian might be a more suitable member of the health board than a physician who is not a sanitarian, but it seems to him that the professional sanitarians we need are men who have a medical education in the first instance, and added to that the necessary training to make them sanitarians. He thinks a great many physicians and health officers in this country appreciate the fact that a trained body of medical men who are specialists in sanitary work is needed. At the present time there is no regular system of training, and no place to go and pursue such a course of study. There is some prospect in Washington of being able to present such a course to those young medical men who desire to be sanitarians; the course will last for two years and lead up to the degree of Doctor of Public Health. The program has been made out by the president and trustees of Columbian University, which is soon to be called the George Washington University. The faculty has been selected. Dr. Sternberg is to be the dean, and among other members of the faculty are Dr. Wylie of the Agricultural Department, Dr. Salmon, and Dr. Stiles, who is an expert in everything relating to animal parasites. Dr. Wyman is to give lectures on quarantine administration, and Dr. Woodward on municipal sanitation. Dr. Sternberg is to have the general subject of hygiene. One or two distinguished lawyers and one justice of the supreme court, who is connected with the Columbian Law School, will give instruction with reference to sanitary laws, and the limitations placed by the constitution on legislation. They expect to have a competent sanitary engineer. The trustees have approved the plan, and there is only one thing at the present time that prevents them announcing that they are ready to receive students, and that is the lack of money. The trustees have decided that such a department shall be established as soon as $250,000 can be secured as an endowment or a guarantee fund of $50,000 to carry on the work of the department for a period of five years. If any wealthy gentleman will come forward with the guarantee fund they will be prepared to start the Department of Public Health. Dr. Sternberg believes if it could be fairly started that in the course of a few years they could begin to turn out thoroughly trained sanitarians. They will admit to the course non-graduates in medicine in order that they may take advantage of the instruction, but they can not receive a degree. The time will come when public sentiment in this country will demand that there shall be on every board of health at least one trained sanitary expert to whom all questions can be referred, who will conduct the laboratory work, etc.

Dr. G. T. Swarts, Providence, R. I., suggested that the trustees interview brothers Rockefeller and Carnegie.

Dr. Seneca Egbert, Philadelphia, believes the time will come when just such a school as this will be demanded; and when it begins to turn out its graduates we will then have sanitary districts, each with its proper sanitary officer. This plan is now in vogue in England. The United Kingdom is subdivided into sanitary districts, and in each of the sanitary districts there must be a sanitary officer, who is usually a graduate of just such a school and with such a degree as Dr. Sternberg has described. Dr. Egbert said if we can make the dairymen understand that by improving the conditions of their dairies and making them more sanitary and more nearly normal they are going to help themselves economically, we will reflexly help ourselves and our people, because as the dairy improves so will the quality of the milk improve. We must impress on the dairyman the necessity of putting his cattle in the best hygienic condition possible. Dr. Egbert believes that much of our tubercular infection comes from the milk and food we consume. He believes that the usual way of infection is through the alimentary tract into the lacteals, thence up through the thoracic duct to where it enters the subclavian vein. The chyle is poured directly into the subclavian vein just before the blood goes into the vena cava and heart, and from there right into the lungs. The material that goes into the body by way of the thoracic duct must go directly to the lungs, and the first place where it meets any marked obstruction to its progress is in the capillaries of the lungs.' Everywhere else it has a comparatively large lumen to pass through.

Dr. H. M. Bracken, Minneapolis, said that he does not think the Jews are any more careful in excluding tuberculous meat than are the gentiles. He knows of instances where tubercular cattle were killed under inspection, and the Jewish butchers were ready to take meat of a lower grade than the regular butchers. So far as he can judge, their inspection of meat does not amount to much when it comes to the question of tuberculosis.

Dr. Gardiner Swarts, Providence, R. I., said that there has been a good deal of dispute of late whether animals can infect the human being with tuberculosis, although the trend of opinion is confirmatory.

Dr. R. C. Newton said that, so far as he could ascertain on the eastern seaboard, the percentage of infected cattle was 30 per cent. Whether this is so or not over the entire country, we have no accurate knowledge. Buyers of fancy cattle and men who are trying to get high-class herds have had such an experience that they are beginning to think the disease almost universal. Thirty per cent. among eastern cattle is, perhaps, a low average. New Jersey has just passed a good law, which requires that every health inspector shall be examined as to his fitness and be licensed. The present inspector in Montclair is a graduate of the Massachusetts Institute of Technology. Those men are educated along the lines of chemistry and bacteriology better than the average physician. An epidemic of typhoid fever which occurred in Montclair in 1894 resulted in giving the health board more power than perhaps any other health board in the state. They have regularly employed an expert inspector since then. He has an analysis made of the milk delivered by every dealer every month, and that analysis is posted on the wall in the office of the board of health and any one can go in there and find out whether he is getting milk with 30,000, 40,000 or more bacteria to the c.c. or not. The more careful dairymen are getting all the business. Public opinion must be elevated considerably above its present status in order that the health boards may have proper authority to issue licenses to all dairies and to revoke the license of any dairy not properly administered. It is a matter of common report that the Jew is remarkably exempt from tuberculosis, and many observers have asserted that the careful inspection of their meat is at least one cause of this. It has been stated on good authority that out of 10,000 Jews in New York City one will find only 79 cases of tuberculosis, while among 10,000 Irish in the same place one will find 660; among the Swedes, 500, and among the Americans over 200. If we knew the reason for this we would be able to do something definite towards solving the great problem of the predisposing cause or causes of human tuberculosis. Dr. Bracken thinks hygienic laws and general habits have a great deal to do with it, but he does not think the meat has anything to do with it.

IS PNEUMONIA INCREASING?*

JOHN S. FULTON, M.D.
BALTIMORE.

The generally accepted view that the pneumonia mortality has risen rapidly in late years rests on no other evidence than the apparent mortality rates and ratios. If the rates and ratios are in general delusive, and if with respect to pneumonia they are shown to be fallacious, it does not follow that we must diminish our respect for pneumonia as a cause of death, but that we must more accurately determine its important relations.

---

* Read in the Section on Hygiene and Sanitary Science of the American Medical Association, at the *Fifty-fifth Annual Session*, June, 1904.

I shall use the ratios almost exclusively in this study, because the disturbing factors of mortality ratios are more easily ascertained than those of the death rates, and the ratios are less influenced by the vagaries and inconsistencies of registration.

The apparent rise of pneumonia dates from the beginning of mortality registration in this country, and has over and over again been the subject of remark. In 1889 the registration report of Massachusetts comments on the apparent rise of pneumonia mortality above the age of 60, but no remark is made on the statement that the ages below 15 had suffered 36.12 per cent of the pneumonia mortality during the previous 20 years. Its apparent rise since 1890 has, however, brought pneumonia prominently into view, and this period (since 1890) has been most discussed. In a study of the mortality reports of the United States Census for 1890 and 1900 Klebs pointed out the interesting fact that the pneumonia mortality between the ages of 15 and 60 diminished from 1890 to 1900, while the periods of childhood and old age carried an increased burden of mortality. It also appears from the census statistics that the whole burden of the alleged increase fell on cities. Taking the study back to 1880 one finds the same distinctions, but I believe it has not before been remarked that the distinctions of age and of urban mortality were more marked in 1880 than in 1890. In 1890 37.7 per cent. of the pneumonia mortality of cities fell under the age of 15; in 1900, 45.5 per cent. fell on the same period of life; but in 1880 the children bore 48 per cent. of the pneumonia mortality. If these figures contained the whole truth of the matter we should believe that pneumonia under 15 had decreased in cities since 1880. But it happened that between 1880 and 1900 the age distribution of the population in American cities altered very materially.

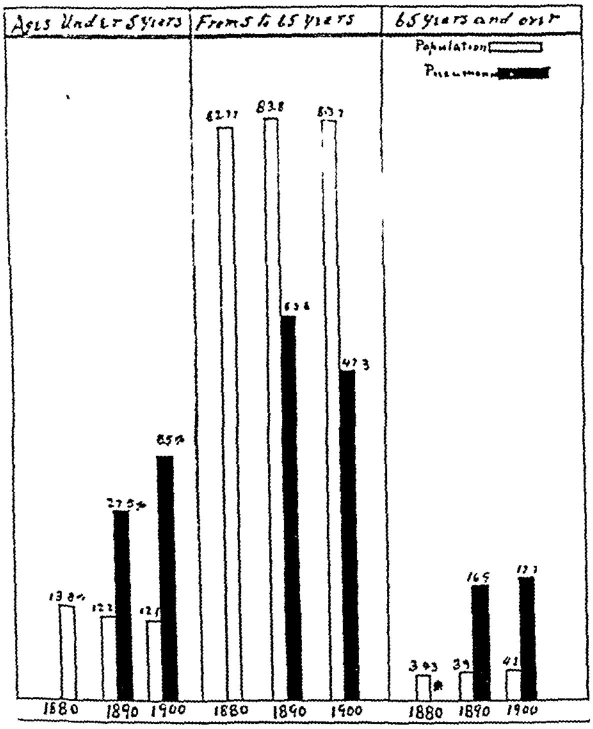

Chart 1.—United States census figures for 1880, 1890 and 1900. Population percentage in 3 age periods. Pneumonia mortality percentage in 3 age periods. *Pneumonia for 1880 unknown.

A glance at the charts (1 and 2) showing the curves of population and of pneumonia mortality, distributed by quinquennial age periods, will bring into view the first correction which must be applied to mortality ratios.[1] Unfortunately the distribution of urban population in 1880 is not shown, but the general age distribution of population in that year shows that cities had a considerably larger proportion of children in 1880 than in 1900. The 45.5 per cent mortality of 1900 fell on 30.3 per cent of the population. If, as seems probable, the 48 per cent. mortality of 1800 fell on 35 per cent. of the population, then 48 per cent. in 1880 was really a lighter load than 45.5 per cent. in 1900. Here we find the true relations diametrically different from those which were at first apparent. Not a city in this country probably, and certainly not one of those cities where the apparent rise of pneumonia has excited most comment, can apply this fundamental test to its mortality statistics.

Next we must try the ratios by what we know, or think we know, about the causes of death.

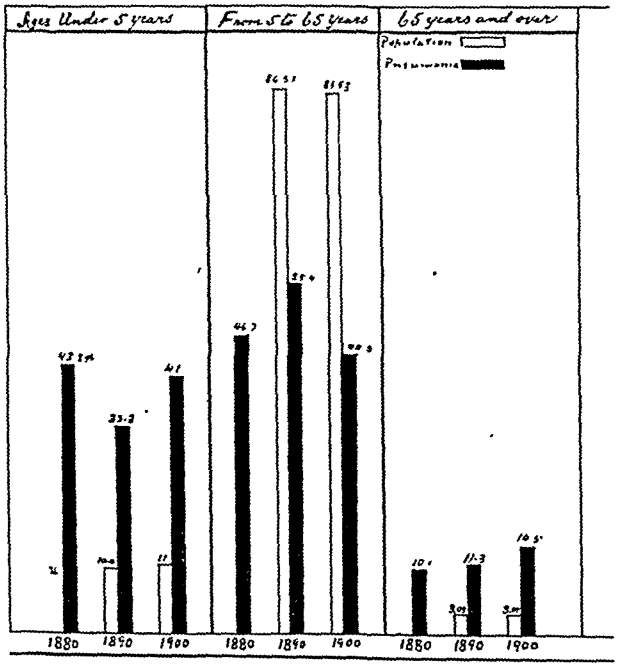

Chart 2.—United States Census, 1880, 1890, 1900. Percentages of urban population in 3 age periods. Percentages of urban pneumonia mortality in 3 age periods. Urban population for 1880 unknown.

The apparent ratios of death from pneumonia to deaths from all causes since 1850, as displayed in the United States reports, are as follows:

		Increase.	Per cent.
1850	.... 37.55 per 1,000 deaths		
1860	.... 68.74 per 1,000 deaths	31.19 points	83.00
1870	.... 81.28 per 1,000 deaths	12.54 points	18.24
1880	.... 83.30 per 1,000 deaths	2.02 points	2.5
1890	.... 87.37 per 1,000 deaths	4.07 points	4.8
1900	....106.1 per 1,000 deaths*	18.73 points	21.46

*Known causes.

Note that the twelfth census states for the first time the ratio of pneumonia to known causes. The previous ratios included unknown causes and need corrections which the reports appear to furnish, though unfortunately we can not rely upon their accuracy.

---

[1] The original charts (1 and 2), showing quinquennial age curves, could not be satisfactorily reproduced. The charts here substituted, showing but three age periods, illustrate the argument less forcibly. The same remark applies to Chart 12.

The deaths from unknown causes are said to have varied from 1850 to 1900 as follows:

1850	13.69	per cent. of the total mortality
1860	11.1	per cent. of the total mortality
1870	3.5	per cent. of the total mortality
1880	4.9	per cent. of the total mortality
1890	3.916	per cent. of the total mortality
1900	3.904	per cent. of the total mortality

Correcting our apparent ratios for pneumonia, we shall have: (Chart 3.)

		Increase.	Per cent.
1850	43.50 per 1,000 deaths		
1860	77.33 per 1,000 deaths	33.83 points	75.4
1870	84.23 per 1,000 deaths	6.90 points	9.0
1880	84.44 per 1,000 deaths	.21 points	.25
1890	90.06 per 1,000 deaths	5.62 points	6.6
1900	106.1 per 1,000 deaths	16.04 points	17.8

Meanwhile our views have altered as to what are unknown causes. In 1850 a death from "fever" was a known cause. So were deaths from "wasting," "worms," "teething," "rage," "fright," "grief," "congestion of the heart," "paralysis of the lungs," "swallowed a penny when a boy," and other absurdities, traceable in the statistics down to the later nineties.

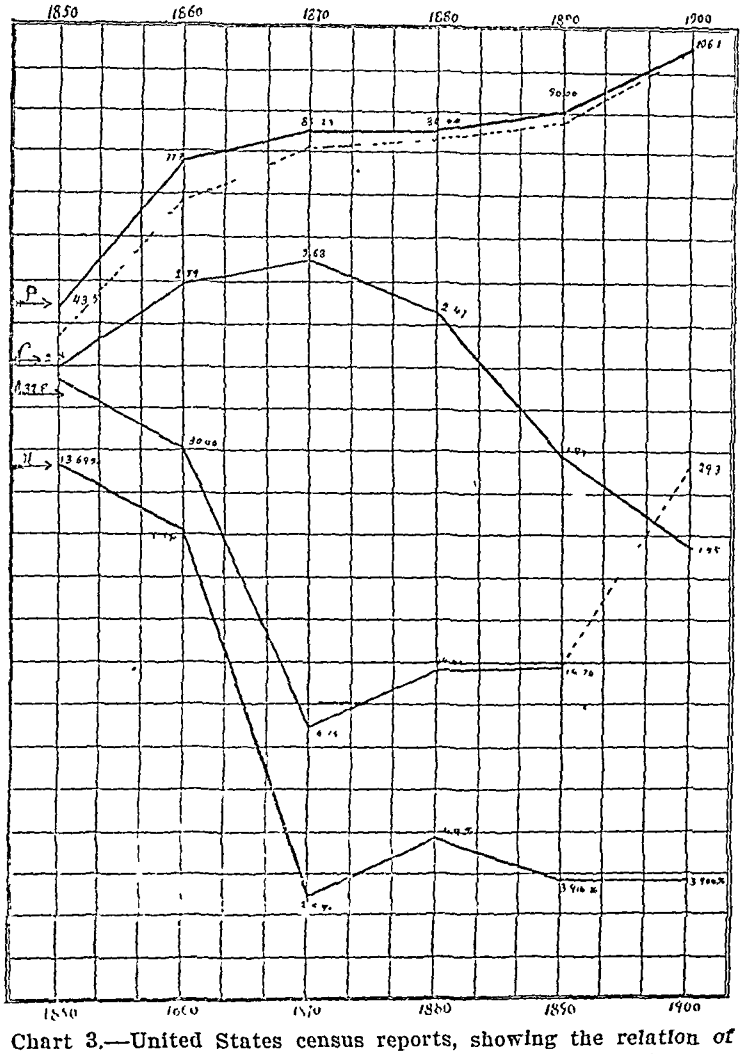

Chart 3.—United States census reports, showing the relation of pneumonia to unknown and indefinite causes of death. P, pneumonia; C, convulsions; A, old age; U, unknown causes.

In 1900 the unknown class includes debility, wasting, heart failure, infantile atrophy, marasmus, inanition (above the age of three months), *laparotomy, paracentesis*, phlegmasia, pneumatosis, polydipsia, polyuria, surgical shock, strangulation, stricture, suppuration, tympanitis, typhomania, rupture of viscera, and 27 sorts of fever, all of which in 1870 were considered definite enough to be classified among known causes.

The percentage of unknown causes for the year of 1850, if brought into accord with modern ideas, would be much more than 13.7 per cent. of all the certificates examined, and the percentages for intervening years would be materially increased, thus further diminishing the differences in our pneumonia ratios. The published pneumonia rates for the various localities of this country are all uncorrected for unknown causes, and there is no means of ascertaining what the error is on this account, but certainly a descending scale beginning *with a percentage of 13.7 in 1850 and ending with 3* in 1900, would not fully correct the ratio of pneumonia to known causes of death.

The state of Connecticut publishes a percentage table of unknown causes, though the ratios are not corrected by it. In 1878 the percentage of returns giving unknown causes of death was higher than that of the census for 1870, and this fact supports the view that the census percentages are very much too small. In 1878 Connecticut was a registration state, collecting her mortality data day by day at the time and place of death; while the United States Census Reports depend on the returns of a very few registration states and cities, supplemented, or confused as the case may be, by the reports of unskilled lay enumerators making inquiry in May concerning all the deaths of a preceding twelve months.

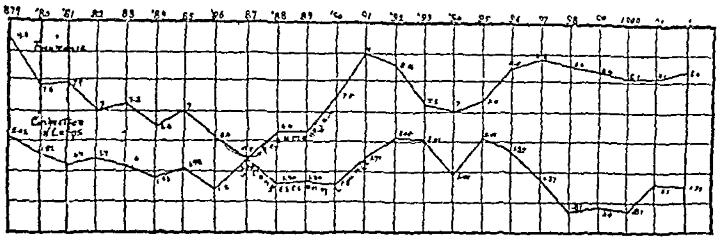

Chart 4.—District of Columbia, showing the symmetrical relations of pneumonia and congestion of the lungs with the striking effect of influenza's advent in 1890.

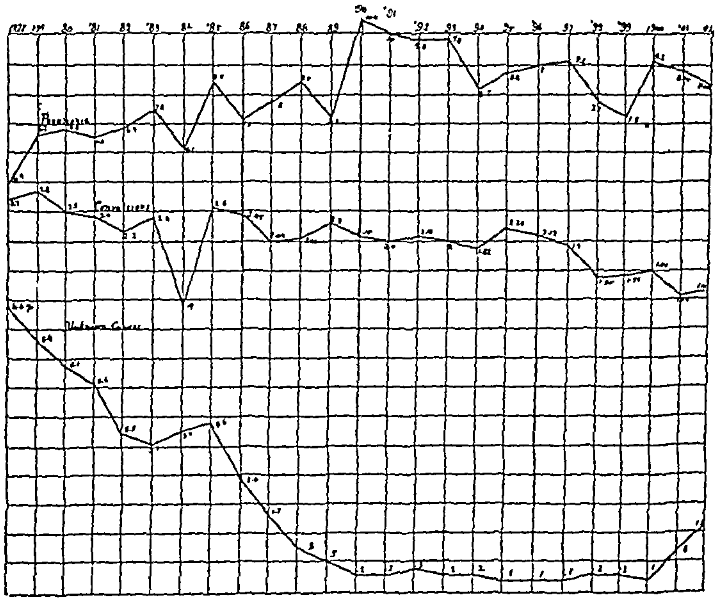

Chart 5.—Connecticut. Showing history of unknown causes. Illustrating the confusion between convulsions and pneumonia. Tendency to diverge in parallel motion. Relation of influenza suddenly appearing in 1890. Unknown causes are included in these ratios.

The Connecticut percentage for unknown causes falls year by year from 6.6 per cent. in 1878 to two-tenths of 1 per cent. in 1890. It does not rise above three-tenths of 1 per cent. until 1901, when the international classification came into use, sending the ratio of ill-defined causes up in two years to 1.3 per cent. Fancy what would happen to the pneumonia ratios of Connecticut if they were subjected to a plus correction beginning at 1.3 per cent. in 1902 and augmented backward to 37.7 per cent. in 1880 (Chart 5).

No statement of unknown or ill-defined causes can be found in Chicago reports. In New York city reports since 1901 one can find the vague causes of death, and they amount to 4 per cent. of the total mortality. Baltimore has been employing the international classification since 1898, but the deaths classed as of indefinite causation are but six-tenths of 1 per cent. The Philadelphia registrar is cleverest of all (Chicago always excepted), for he only finds one certificate in two or three thousand too difficult for his skill at classification. The returns of Maryland, outside of Baltimore, are examined by a medical man, and so large a proportion as 6 per cent. of them are found incapable of classification and unfit for inclusion in the nosologic ratios.

Boston is silent about indefinite causes of death until 1902, when the international classification went into use, and the indefinite causes of death are found *to be about 4 per cent.* The Massachusetts registration reports give us a clue to the probable history of vague causes in Boston. The indefinite causes of death shot up in a remarkable way in 1868, when vague returns for deaths of infants were taken out of the infantile class and passed into the unclassified account for all ages. The percentage of unknown causes shot up from 1.9 per cent. to 5.4 per cent. of the total mortality, and from this point it fell to 1.17 per cent. in 1889. If the 4 per cent. correction for unknown causes in Boston in 1902 be multiplied backward to 24.8 per cent. in 1882, what will then be the relation of the ratios of any definite cause of death? If the experience of Massachusetts and Connecticut indicates so large a source of error in undefined causes, how can the error be less in Chicago or New York?

Moreover, the age distribution of the unknown and ill-defined causes of death shows that this correction applies but slightly to the middle period of life, 40 per cent. of it falling on ages under 5 years, and a small excess again on ages over 60. These corrections would undoubtedly moderate the remarkable angularity of the published pneumonia curves, and might even cause its apparent general rise to disappear.

The Massachusetts correction applied to the census figures would change the pneumonia ratio for 1880 from 83.30 per 1,000 deaths from all causes to 98.54 per thousand deaths from known causes, reducing the apparent rise of 22 points to a rise of less than 8 points in 20 years.

Statistical compartment No. 179 is not the only waste basket in our nosologic classification. Each class of diseases has a special receptacle for the certificates which appear to belong to a definite class of diseases but not to a definite nosologic title.

Old age furnishes a statistical history somewhat suggestive, though less interesting than that of undefined causes. The ratios of old age to the so-called known causes of death are, according to the census reports, as follows: (Chart 3.)

		Increase or Decrease.	Per cent.
1850	.... 32.8 per 1,000 deaths		
1860	.... 30.6 per 1,000 deaths	—2.2 points	—6.7
1870	.... 16.75 per 1,000 deaths	—13.85 points	—45.9
1880	.... 19.61 per 1,000 deaths	+2.86 points	+17.00
1890	.... 19.74 per 1,000 deaths	+.13 points	+.66
1900	.... 29.3 per 1,000 deaths	+9.56 points	+48.4

If old age were a cause of death, its ratio to total mortality should have steadily and very materially risen in 50 years, for the proportion of population above the age of 65 has risen. We find, however, that the mortality ascribed to this cause fell for twenty years, and in the next 30 years rose slightly. The apparent rise of mortality since 1890 can not, however, be explained on the view that a larger proportion of deaths were returned under this vague title. The experience of all registration states is contradicted by the figures for these wide apart years, for everywhere old age is diminishing as an alleged cause of death, though everywhere old age as a phase of human life is increasing. The deaths of the aged are nowadays far more definitely explained than 20 years ago. Of those lost to the indefinite account many have gone into the accounts of cancer and of kidney diseases, but some have gone into the pneumonia account. The apparent rise of pneumonia in the aged is fully accounted for by the increased population at advanced ages, added to the improved certification resulting from better diagnosis.

In the class of respiratory diseases there is a vague title which undoubtedly conceals part of the pneumonia mortality. It is "congestion of the lungs," a title signifying as much in vital statistics as it does in medical

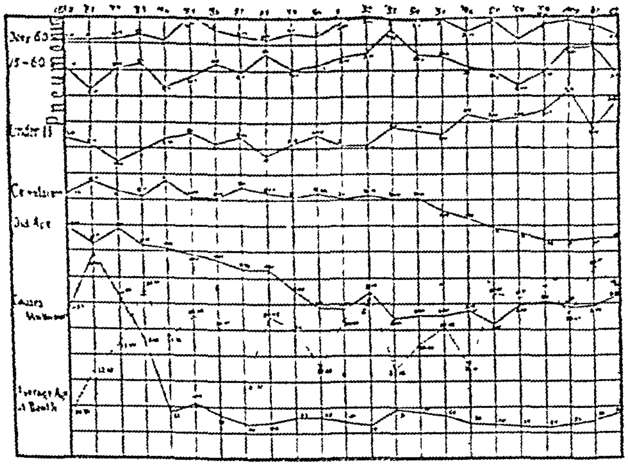

Chart 6.—Rhode Island. Showing an indefinite cause of death, "old age," declining while the average age at death increases and the pneumonia mortality above 60 does not rise. Under 15 years pneumonia rises while convulsions decline. These ratios are to total mortality, including unknown causes.

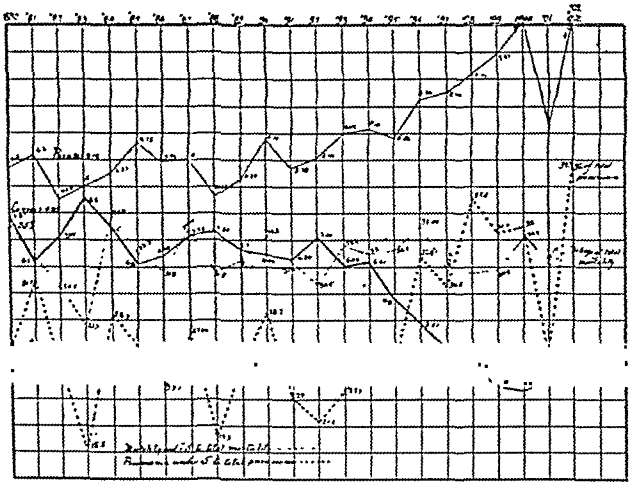

Chart 7.—Rhode Island. Showing apparent rise of pneumonia under 5, with coincident decline of convulsions and increasing ratio of pneumonia under 5 to total pneumonia. The decline of infantile mortality in general is also shown. Ratios are to total mortality under 5 and include unknown causes.

diagnosis, and no more. The District of Columbia[1] reports show the progress of this statistical item for many years. Observe chart 4, which shows pneumonia and congestion of the lungs diverging steadily year by year in parallel motion. Its responsiveness to the pneumonia curve shows that congestion of the lungs, in the District of Columbia at least, is not an empty title, although it has been unloading into the pneumonia column for years.

Certain obscure or ill-defined diseases bear relations to infantile mortality quite analagous to those borne by old age to the mortality above 60, and by unknown causes to the total mortality. One of these statistical titles has a close relation to the pneumonias of children, namely, "convulsions." Statistics of mortality from convulsions are available from 1850 to the present time. (Chart 3.) Their history in the United States Census is as follows:

	Per 1,000 deaths from all causes.	Per 1,000 deaths from known causes.
1850	18.8	21.8
1860	23.04	25.9
1870	25.9	26.8
1880	23.6	24.7
1890	18.9	19.7
1900	.....	15.5

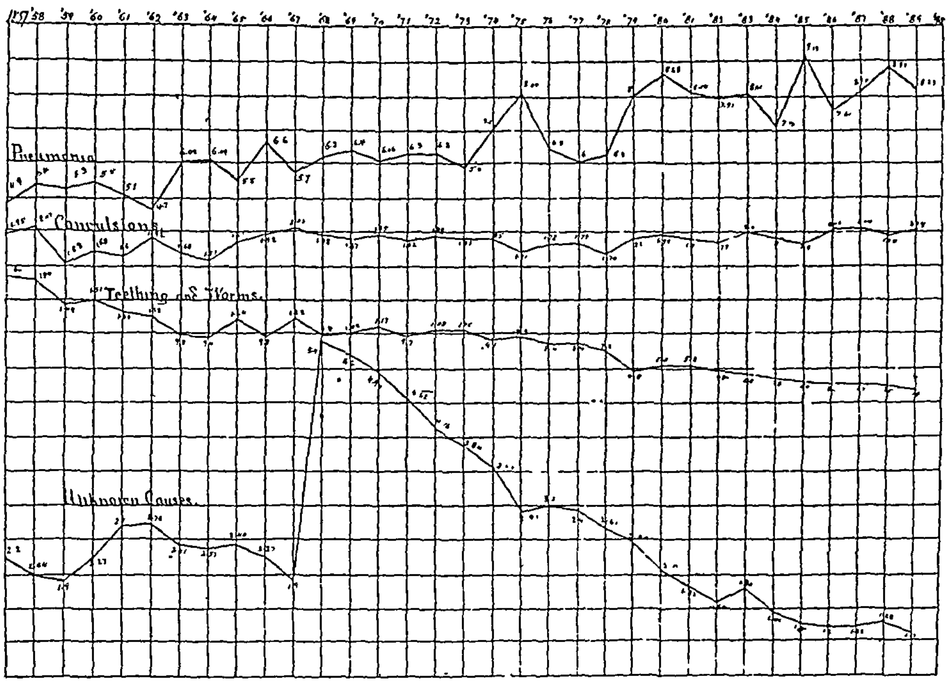

Chart 8.—Massachusetts, 1857 to 1890. Showing progress of the pneumonia ratios for all ages in relation with the progress of "unknown" causes and with two indefinite causes.

For the last decade, while pneumonia has been rising from 90.06 to 106.1, convulsions have fallen from 19.7 to 15.5 per 1,000 deaths from known causes. In the same period the death rate, for convulsions, per *100,000* population, has fallen from 56.2 to 33.1. The ratio of convulsions per 1,000 deaths from known causes at known ages has dropped from 33.5 to 2[illegible]4.

The relations of convulsions to quinquennial periods under 15 are as follows: In each 1,000 deaths under the age of 5 years there were charged to convulsions in 1890, 67.05; in 1900, 59.5. In each 1,000 deaths between 5 and 10 years, 15.44 in 1890, and in 1900, 11.3 were charged to convulsions. In each 1,000 deaths between 10 and 15 years of age there were charged to convulsions in 1890, 8.45; in 1900, 5.3. This is a remarkably consistent statistical exhibit of the progress of the mortality records toward definiteness.

Convulsions in children mask pneumonia more than any other cause of death, and one can safely say that a major part of the diminishing mortality from convulsions has, through improving diagnosis, been transferred to the pneumonia account, though from the statistical point of view this means no more than a step or two toward definiteness. At the present time every textbook warns one not to be misled by convulsions into overlooking pneumonia, and the importance of convulsions in the symptomatology of pneumonia is strongly emphasized. The diagnosis of pneumonia in children is indeed a very modern refinement of medicine, and dates from the comparatively recent inclusion of pediatrics among the essential subjects of college training.

One can not derive from the published statistics of large cities the relations of convulsions to pneumonia, but it seems quite significant that the weekly bulletin of Chicago has recently commented on the 40 per cent. decline of mortality from nervous diseases in the present decade, as compared with the decade preceding. The great part of that gain is a 60 per cent. reduction of the mortality from convulsions. It will be safe to say that 95 per cent. of the deaths charged to convulsions in Chicago fall on the period of life below 5 years, and that no more than 15 per cent. of these cases were in any proper sense diseases of the nervous system. A majority, at least, of these cases were pneumonia, and undoubtedly the pneumonia account has fattened on the alleged decline of nervous diseases.

The relations of pneumonia to convulsions are shown on several of the accompanying charts, and here, as in the case of congestion of the lungs, one observes a tendency to rise and fall together, particularly in the earlier part of the history. They diverge, however, the convulsions line pursuing a general downward course as pneumonia tends to rise.

For the state of Rhode Island I have been able to separate the pneumonia ratios by age periods, charting separately the pneumonia ratios for ages under 15 (Chart 6), from 15 to 60, and above 60. This brings out the relation of convulsions to infantile pneumonia rather better, although the statement is not quite fair to that relation. The relations of pneumonia under 15 to convulsions would be better stated as ratios *to the* mortality from known causes under 15 than to the mortality at all ages. The published figures would not yield these ratios, but Dr. Swarts has kindly furnished me figures which yield a still more striking illustration, namely, the relations of pneumonia and convulsions under 5 years to the total mortality under 5 years, the relations of pneumonia under 5 to pneumonia at all ages, and of the mortality under 5 to total mortality;

---

[1] The apparent pneumonia history of the District of Columbia has attracted much attention as the "exception." The crude statistics indicate a decline of pneumonia. The age distribution of the population of Washington is very different from that of any other city in the country. In this respect it resembles none of the states adjacent. The population of Washington is deficient below the age of 20 and above the age of 60 years. It lacks precisely the elements of population which are said to have suffered the increased incidence of pneumonia. The average age at death has steadily increased, but it is doubtful if the average age of the living has materially altered in Washington in the past 20 years. If the statistics of Washington could be studied for pneumonia under the age of 5 years, it should and probably would appear that the returned mortality for pneumonia has increased, but the tables do not yield the necessary data, though Washington prints better statistics of mortality than any other large city in the country.

all for the period of time covered by the preceding chart (Chart 7).

The chart for Massachusetts contains, besides convulsions and unknown causes, the mortality ratios for "teething" and "worms." In 1897 only 1.3 deaths in "worms" are given definite consideration in the mortality statistics of Massachusetts down to the year 1900, when these items were lost by the adoption of the international classification. The relations of "teething" and "worms" to present-day mortality may very well be ignored, but their relations to our vital bookkeeping in the past may not be ignored. In 1857, 18.6 deaths in every 1,000 deaths at all ages, were attributed to "teething" and worms." In 1897 only 1.3 deaths in 1,000 are found under these heads. Different and more definite relations of infantile pneumonia are shown in Chart 9 from the experience of Massachusetts between 1889 and 1902.

A single registration office that I know of keeps separate account of the diseases of the brain and nervous system of children. My friend, Henry Mitchell, of New Jersey, furnishes this statistical account for comparison with the pneumonia account. The graphic statement is quite a remarkable one, showing the two curves separating in parallel motion so uniformly as to leave no doubt, in my mind at least, that the pneumonia account is fattening on the decline of its too responsive companion. Let me remind you again of the diagnosis of pneumonia in children. Its symptoms may include convulsions, stiff neck, opisthotonos, Kernig's sign, and the tache cérébrale, the cardinal signs, till recently, of meningitis. (Chart 10.)

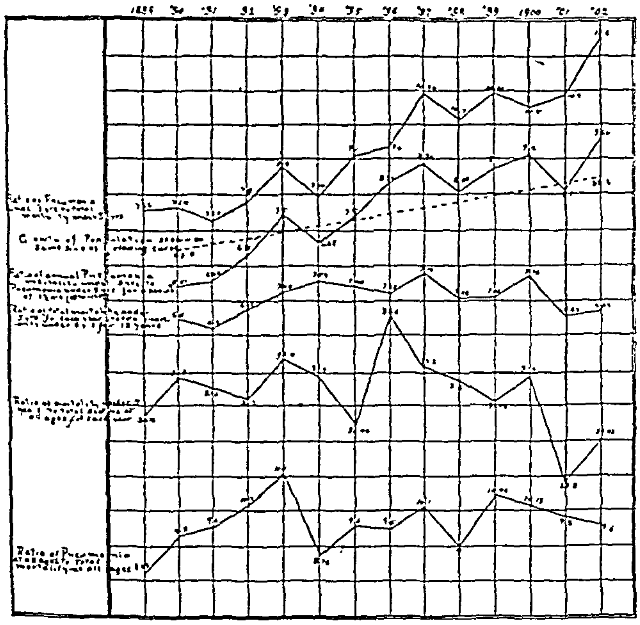

Chart 9.—Massachusetts, 1889 to 1902. Showing apparent rise of pneumonia under 5, increasing independently of the proportionate general mortality for that age period; showing the ratio of pneumonia for each year to pneumonia for 13 years, in the age period under 5, increasing but slightly in excess of growth of population.

For the state of Michigan I have been able to chart the ratio of pneumonia under 5 to the mortality from specified causes under 5, and to show the progress of convulsions and of unknown causes in the same relations. The relations of all these curves to the proportion of total mortality borne by children under 5 is also shown. A particular point of interest in this chart is the extremely irregular curve of unknown causes. Of course the unknown causes pursued in reality no such eccentric course. Rather does it indicate that Michigan registrars were like the rest of us, long in acquiring the Socratic merit of knowing that they did not know. From 1884 to 1889 a large number of obscure causes of death in infancy appear to have been restored to the classified nomenclature. If the plan of compilation used in 1883 had continued in use to 1889, the ratios would have traveled as high as they do in the nineties until 1897, when a much more stringent exclusion of vague causes was practiced, sending up a ratio that otherwise would have fallen. (Chart 11.)

In this state, too, the advent of influenza in 1890 had a remarkable effect on both pneumonia and convulsions. Both the ratios fall a long way in obedience to the strong impression made by the grip on the medical mind and probably also on the registration office. This precipitate decline marks the period when the physicians and registration officers of Michigan came very near calling a spade a spade, though they have, in common with physicians and registrars elsewhere, been hiding influenza in the pneumonia account ever since that year.

One must regret that the mortality statistics of the large cities can not be studied from the published reports. It is a reproach that the mortality of these cities is not at least put into condition for study before publication. The fact that crude statements are published without any mention of their elements, is of itself sufficient ground for refusing them credit. For New York it may be said that it is difficult to find collateral evidence of the delusiveness of her pneumonia statistics. Chicago, however, does not confine her remarkable statements concerning mortality to the subject of pneumonia. Some of Chicago's detached utterances are difficult to reconcile. For instance, when we are told that from November, 1903, to May, 1904, there were 3,568 deaths from pneumonia, one may ask whereabouts on the population the mortality fell?

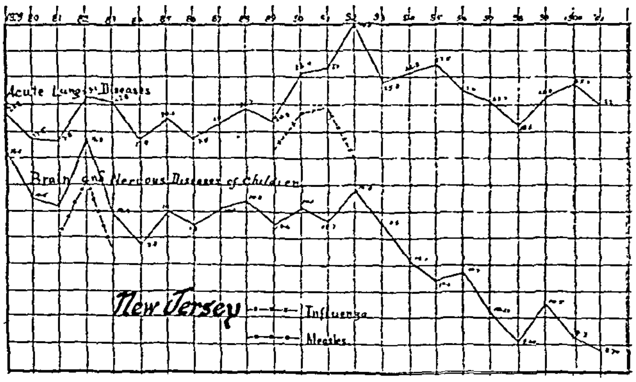

Chart 10.—New Jersey. Showing the mortality account of brain and nervous diseases of children unloading into the mortality account of acute lung diseases. The chart at 1892 suggests marked alteration either in the death certification or statistical treatment of influenza.

Above the age of 65, Chicago has but 2.46 per cent. of her population. The large American cities (including Chicago) have 3.07 per cent. of their population above 65. The Chicago figures for pneumonia impose a mortality 30 per cent. excessive on a population 20 per cent. short. One can not compound mortality at this rate.

At ages between 5 and 65 pneumonia is declining, and Chicago should derive a profit from this fact, for she has 86.3 per cent. of her people in this period, against the 85.93 per cent. in other large American cities. The excessive mortality can not fall on this period.

Chicago has below the age of 5 years, 11.24 per cent. of population, against 11 per cent. in this period in other large American cities. This part of the population, according to urban experience in recent years, must carry approximately 46.4 per cent. of the pneumonia mortality.

According to a recent bulletin the present proportion of deaths under the age of 5 is 21.8 per cent. of the total mortality, about 4 points less than it has been in years. The pneumonia mortality of Chicago is said to be 22.32 per cent. of the total mortality. The use of exactly these figures would result in an absurdity so gross that I hesitate to utilize it. Let us assume as Chicago's proportionate mortality what she says is her average, 26 per cent., and we shall have the statement that 26 per cent. of all deaths include not less than 37 per cent., and perhaps as much as 46 per cent. of the deaths from that cause which itself causes 22.32 per cent. of the total mortality. The arithmetical result of this sad disarrangement is that of every 1,000 deaths in Chicago under the age of 5 years, between 318 and 471 must have died of pneumonia.

There is no conceivable way of adjusting 3,568 deaths from pneumonia to the roll of the living or the dead in Chicago without producing as absurd relations as these. Instead of 21.8 per cent., 31.8 per cent. of total mortality for the period of life under 5 years is the lowest figure possibly consistent at the same time with human experience and with Chicago's reported pneumonia mortality. On the other hand, if 21.8 per cent. is approximately the proportionate mortality of Chicago for the age period under 5 years, the pneumonia mortality must be counted down from 3,568 to 2,880 before it reaches the limits of credibility.

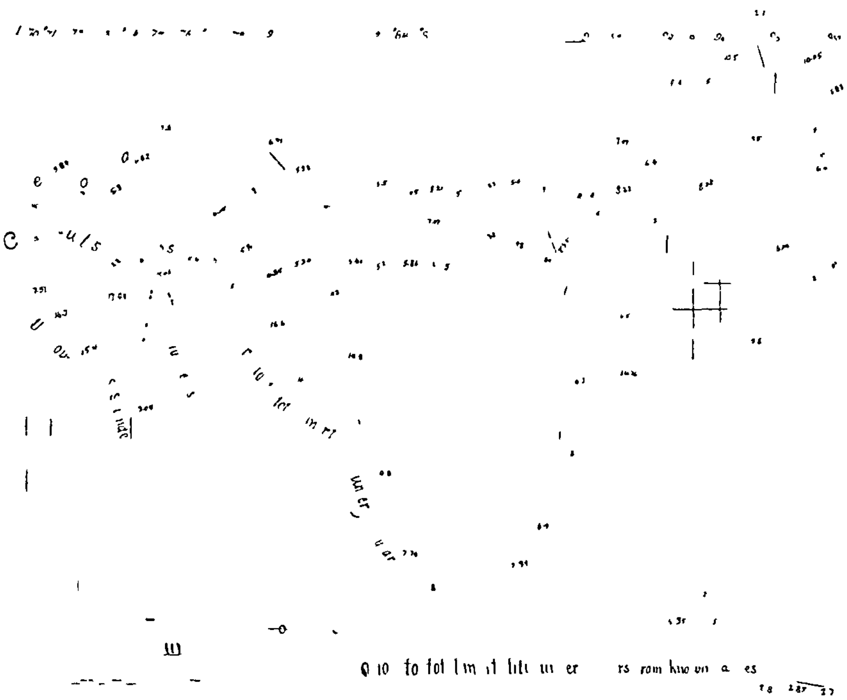

Chart 11.—Michigan. Illustrating the confusion of pneumonia with convulsions, especially in the years 1871, 1878, 1881, 1882 1883, 1888, 1889, 1890, independent of the fluctuations of unknown causes—in the years 1891, 1892, 1893, 1897, 1898 the same confusion exaggerated by the fluctuation of unknown causes. At the year 1890 the chart derives its peculiar character from the reference of many deaths under 5 to influenza—convulsions and pneumonia, both falling, notwithstanding a large rise in the unknown causes. Unknown causes are excluded from the ratios.

The bulletin says again that the present season is the most favorable in the history of the city so far as childhood is concerned. Great gratification is expressed at the "phenomenal infrequency of the contagious diseases." Since the first of the year there are said to have been but 9 deaths from measles, against 190 in a like period last year, but 91 deaths from scarlet fever against 167 in a like period last year, but 8 deaths from whooping-cough against 186 in a like period last year. Now Chicago is on earth. It is situated in one of the United States, is inhabited, and its people have the characteristics of the human race, except that they can suffer a phenomenal rise of pneumonia, associated with a more phenomenal fall of measles, scarlet fever and whooping-cough. In this respect the history of Chicago in 1904 is unique in the experience of Illinois, of the United States, of the world, and of Chicago.

These representations of the history of indefinite causes in general exhibit the progress of medical diagnosis and of registration in the general direction of definiteness. They show that improvement in medical diagnosis has a far more serious effect on the significance of the figures than is generally admitted. In the history of the very indefinite and unknown causes one sees so large an error as to vitiate the statistics for practically all the definite diseases, which are said to be rising. In the infantile mortality especially, one sees a number of vague causes of death gradually disappearing from the tables, while most of the definite affections are at the same time declining. There is but one possible explanation of the declining mortality charged to such vague statistical accounts as teething, worms, convulsions, brain and nervous diseases of children, and that explanation is that deaths long ago attributed in large numbers to these causes are now receiving at the hands of physicians more definite nosologic reference.

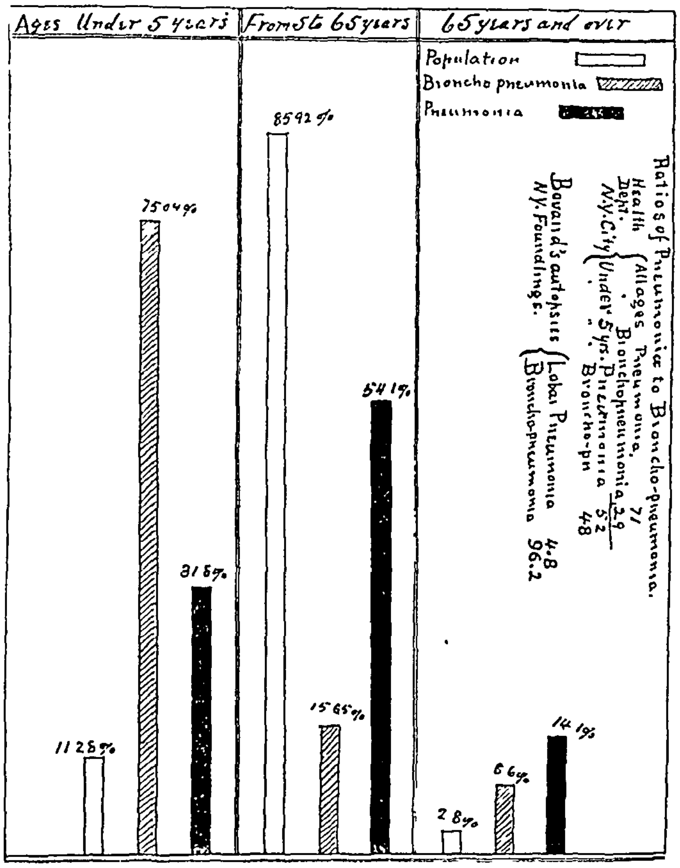

Chart 12.—New York City, 1901. Percentages of population in 3 age periods. Percentages of pneumonia mortality in 3 age periods. Percentages of bronchopneumonia in 3 age periods.

Certain important diseases of infancy are declining, and their decline can be accounted for. A single rising account has appeared in the history of infantile mortality, and the conclusion is to me irresistible, that the one rising account has profited by the decline of the indefinite causes of infantile mortality.

If such corrections as I have suggested be applied to the statistics, we shall, perhaps, not seriously diminish the importance of pneumonia as a cause of infantile mortality at the present time. So far, indeed, the argument simply brings the past and unsuspected importance of pneumonia into view, and at that point we should have to stop if pneumonia were a definite cause of death. But the term pneumonia is not, either in the tables or in its medical use, a definite statement of a cause of death. In medical parlance pneumonia has grown less definite in the course of time. In statistics the term is less definite than in medicine, although it preserved the appearance of definiteness until the adoption of the international classification, when the comparatively modern compounded word, bronchopneumonia, received a separate index.

In the United States census for 1900, although the international classification is used, one finds under the head of pneumonia no differential statement such as this classification provides for. For the local registration offices in general, one may say that differential statements can rarely be found in the published records where the international classification is not used, while in the offices employing this classification differential statements are obtainable only for the past three or four years.

All the statistical sources utilized in this study give differential statements for a total of 13,608 deaths, of which 9,263 were returned under the head of pneumonia, and 4,340 under the heads of bronchopneumonia and pleuro pneumonia.

The published reports for New York furnish hardly any and those of Chicago no means whatever of determining the probable line of cleavage between the two sorts of pneumonia, but if the per cent. derivable from the figures given hold good for these cities, 32 per cent. will be cut off the returned mortality for the past four years. One can not say, however, that the 32 per cent. error which is fairly chargeable against the records for the years 1900-1902 would hold good for any equal antecedent period. The information yielded by the New York City report for 1901 is shown in Chart 12.

The statistics for Boston throw a curious light on this point. The pneumonias were differentiated in that city in the published reports before 1900, but they were distributed in such a way as to make it appear that lobar pneumonia has been decreasing, while bronchopneumonia has been increasing. The bronchopneumonia for 1896 was 15 per cent. of the whole pneumonia account, in 1897, 17 per cent., and in 1899, 22 per cent. Since 1900, 46.7 per cent. of the pneumonia account of Boston is made up of deaths returned as caused by bronchopneumonia.

One might say that it is right to add bronchopneumonia to pneumonia now, the figures should be recovered and added to the pneumonia of the past. But the rise of bronchopneumonia does not mean in medicine and it should not mean in statistics anything added to pneumonia. Traced backward, bronchopneumonia will be found to disappear, the greater part of it at least, in the bronchitis account.

The correction for certificates returned under the head of bronchopneumonia is a discount applied to the pneumonia ratios at a rate beginning with at least 32 per cent. in 1902, and diminishing year by year to zero at about the year 1880.

This would still leave a considerable though indeterminate amount of bronchopneumonia in the figures for recent years. The terms pneumonia and bronchopneumonia, although convertible terms in statistics, are not convertible terms in medical use. No physician ever writes "bronchopneumonia" on a death certificate when he means lobar pneumonia, but many physicians write simply "pneumonia" when they have recognized the cause of death as bronchopneumonia. Bovaird's recent figures for 500 autopsies at the New York Foundling Asylum gave 95.2 per cent. of bronchopneumonia to 4.8 per cent. of lobar pneumonia. Fancy the curves on these charts cut to fit this ratio, and one can see the end of the pneumonia sensation. If the bronchopneumonia could, however, be eliminated or distinguished, the pneumonias remaining would still lack a definite significance.

In the manual which presumably governs the practice of officers using the international classification the instructions as to what returns are to be included under each of the two heads are interesting. Pneumonia includes deaths certified as due to acute, alcoholic, apical, croupous, infectious, bilious, typhoid, diplococcus, lobar and vesicular pneumonia, lung fever, inflammation of the lung or chest, peripneumonia, pneumopericarditis, pneumopleurisy, splenopneumonia. The title does not include death certified as due to bacillary pneumonia, caseous, catarrhal or interstitial pneumonia.

Bronchopneumonia includes catarrhal pneumonia, aspiration pneumonia and deglutition pneumonia. The bronchopneumonia of the census does not include the returns of capillary bronchitis. Capillary bronchitis is counted in the census office and in several local registration offices as bronchitis! One has no means of ascertaining what practice was followed previous to 1900, but it is certain that the practice differed from this. Practically everywhere the total pneumonia account includes all the death certificates in which the word pneumonia was used without reference to an antecedent disease of equal or greater statistical importance. In the District of Columbia the pleurisy account carries the pleuropneumonia mortality. The hypostatic, traumatic, surgical, septic, terminal and ether pneumonias are included in the pneumonia account whenever the death certificate fails to mention an antecedent condition having recognized importance as a cause of death.

The age distribution of bronchopneumonia is interesting. A very large part of it—75 per cent.—falls on ages under 15, but no part of life appears to be exempt from it; 25 per cent. is far too much to charge to ages above 15. I have charted the pneumonia and bronchopneumonias separately for New York by ages. Enormous as the disparity appears below the ages of 5 years, the actual contrast is greater. (Chart 12.) If the bronchopneumonias between 15 and 50 were all charged to tuberculosis, the bronchopneumonia statistics would be better and the tuberculosis statistics no worse. Above the age of 60 the use of the term bronchopneumonia does not express antemortem diagnosis.

Our study has gradually narrowed down to the question of pneumonia under 15, and in this period to the one-ninth or so of population under 5 years. Here we find that something like 90 per cent. of the recorded pneumonias have extremely various etiologic relations, and have no right whatever to consideration under a single nosologic head. Outside of mortality statistics, such thing as a primary bronchopneumonia is but rarely recognized. In a great majority of instances the essential cause of bronchopneumonia can be determined clinically, and should be recorded on the certificate. Possibly since 1890 the diagnosis of respiratory affections in childhood has been in a single respect more difficult. Since the advent of influenza many bronchopneumonias are perhaps not referred to their etiologic factor so easily as are the bronchopneumonias of measles, whooping cough, scarlet fever, diphtheria, etc. Bronchopneumonia is a secondary or complicating condition, and whenever the primary causative factor is known a death from bronchopneumonia should receive appropriate statistical reference. When the certificate fails to designate the proper statistical reference, the record should at least be disposed of in such a way as not to obscure the relations of an agent of death as definite and important as lobar pneumonia.

There is no proof that lobar pneumonia has grown more prevalent or more fatal at any period of life. There is no considerable evidence of an increase at any period of life save that under 5 years, and here pneumonia has simply come into view and demands some consideration. Pneumonia is not the "Captain of the Men of Death." The claims of six destroyers stand between pneumonia and the distinction of leadership.

CONCLUSIONS.

1. The returned mortality of the United States for ages between 15 and 60 during the past twenty years shows a diminishing mortality from the class of respiratory diseases commonly returned as pneumonia. Of the pneumonias occurring in this age period a large majority are true lobar pneumonia. Fifty-eight and a half per cent. of the population of the United States, and 66.5 per cent. of the population of cities are between the ages of 15 and 60. The incidence of lobar pneumonia on a major part of the population is therefore diminishing.

2. The return mortality of the United States, for ages above 60, indicate that the mortality from the class of respiratory diseases commonly returned as pneumonia has increased from 21.9 per cent. to 22.6 per cent. in ten years, the population at the same age in the same period having increased from 6.2 to 6.6 per cent.

The urban mortality for the same age has grown in ten years from 16.1 to 19.5, and has been accompanied by an increase of population in that age period laterally from 5.23 to 5.27 per cent. Several pathologic conditions added to the group of pneumonias, and not provided for in statistics, are included in the returned mortality of pneumonia for ages above 60. For 6 per cent. of our total population lobar pneumonia may have increased in the past ten years, though satisfactory evidence of an increase has not been offered.

3. The return mortality of the United States for ages under 15 (about one-third of the total population) shows an apparent rise of mortality for the group of respiratory diseases commonly classed as pneumonia. The acute respiratory diseases of children were in former years commonly mistaken for affections of the nervous system. Year by year for thirty years increasing numbers of deaths formerly found in the indefinite accounts, and in the class of nervous diseases, have been transferred to the class of respiratory diseases and especially to the pneumonia account.

Of the mortality recorded as due to pneumonia under the age of 15 years, not more than 10 per cent. is due to lobar pneumonia. A small though considerable incidence of lobar pneumonia in children under the age of 5 has come into view of late years, but there is no evidence that lobar pneumonia has increased in this age period. The remaining 90 per cent. of the recorded mortality ascribed to pneumonia includes the conglomerate group of bronchopneumonias, nearly all of which are secondary or complicating causes of death, and should be referred in the mortality tables to the primary causes of death.

4. Since 1890 a new cause of infantile mortality has come into view, an acute respiratory infection, attacking infants of 2 years old and under, commonly returned under the diagnosis of pneumonia, sometimes returned as due to a disease of the nervous system, and probably due to influenza.

5. The mortality registration of American cities is in general very poor. The crude rates and ratios offered by certain cities as evidence of a rising pneumonia mortality are inconsistent with the mortality statements concerning other causes of death, and with the characteristics of the populations concerned. They represent a perversion of statistics which must eventually bring discredit on American mortality registration.

DISCUSSION.

Dr. Benjamin Lee, Philadelphia, said that we all remember the criticism of the individual who divided lies into three classes—lies, confounded lies and statistics. Dr. Lee does not second that particular definition of statistics. At the same time he could not help thinking that we were discussing two propositions supposed to be founded on statistics, both of which have been accepted as definite and fixed, and neither of which, to his knowledge, has ever been definitely proved. It seems to him that we might expect 75,000,000 people to consume more alcohol than 10,000,000, but, taking our people as we find them, he does not think that any one can prove that at the present time intoxication is a vice of this country to the extent that it was 100 years ago. At that time a man was hardly considered a gentleman who did not go to bed drunk, while at the present time it is the exception for a respectable man to go to bed drunk. We may be increasing in the use of certain forms of alcohol, but those are the forms which are the least pernicious. The man who drinks a pint of beer does not drink as much alcohol as the man who drinks a glass of sherry, and very much less than the man who drinks an ounce of whisky. It does not seem to him that our present diseases are more due to the use of alcohol now than they were fifty years ago. There are many factors to be considered when we come to make up our minds as to statistical data and results in medicine. One of the most important factors is the question of diagnosis, and following that is the question of nomenclature. Both of these, in the period during which more or less accurate statistics have been kept, have made wonderful changes. Our advances in diagnosis have been very remarkable, and Dr. Fulton has pointed out that an immense number of diseases are now properly reported as pneumonia which formerly were not so reported. Comparatively few physicians now report infantile bronchitis and catarrh. Most of these cases are probably now reported as pneumonia.

Dr. Cressy L. Wilbur, Lansing, Mich., regrets that it is so extremely difficult to go back over the records of any state, or the United States, and obtain thoroughly reliable data as to the age distribution of any particular disease. He said that, in regard to the variations in the distribution of unknown causes in Michigan, perhaps Dr. Baker can throw some light on the matter, as the early records were compiled under Dr. Baker's personal supervision. Not only the methods of compilation change, but the men change who make the compilations. Dr. Baker, in the early compilation of the Michigan statistics, formed a book of practice, which served as a guide to the work. The statistics at that time were compiled according to the classification of Dr. Farr. During Dr. Wilbur's first experience in compilation he used this classification, but he had no guide to its practical employment. He simply used his best judgment. At the Montreal meeting of the American Public Health Association, in 1894, he suggested a new classification. At that time there was no hint or promise of an international agreement. As soon as there was a prospect of a successful international classification, beginning with the Bertillon system in 1898, he began to use it. This system was revised in 1900, the revision going into effect in 1901, since which time he has adhered strictly to the "international classification," as it is now called. That makes four systems that have been used in Michigan, besides one system which was employed by three different compilers, varying in methods to some extent. This shows the necessity of having a proper guide in this matter if our statistics are to be used for comparisons even in the same state, and the international classification, if strictly followed, should give more satisfactory results than those shown by the diagram. The United States Census reports for the year 1900 were for the census year 1899-1900. The international classification was not used for that compilation, so that the results shown in the last line should compare with those for the preceding censuses. The International Commission of Paris in 1900 did not seem to give this question of the proper compilation of pneumonia very much consideration. A distinction was made between bronchopneumonia and "pneumonia," the latter supposed to correspond closely to croupous pneumonia; but, unfortunately, among the deaths reported from "pneumonia" are included many deaths from bronchopneumonia or catarrhal pneumonia, and the statistics are thereby vitiated. Dr. Tatham of the English Registrar General's Office recently introduced a new classification, and now makes four divisions of pneumonia. Epidemic pneumonia is placed among the infectious diseases. Bronchopneumonia or catarrhal pneumonia and acute lobar or croupous pneumonia are stated separately. In the fourth class appears "pneumonia," unqualified, with indications that it is an indefinite term, not to be chosen if possible to specify more definitely. Dr. Wilbur stated that the statistics of pneumonia are also confused by the fact that many deaths from "pneumonia" occur as the terminations of chronic diseases and are merely terminal infections or complications. When pneumonia is the result of whooping cough, measles, or any of those diseases, it should be charged to the primary cause.

Dr. J. N. Hurty, Indianapolis, said that, attracted to this subject by constant reference of the bulletin of the Chicago Board of Health, he commenced to study the matter very closely in Indiana and tabulated and compared the pneumonia periods, as he called them, namely, November, December, January, February and March of each of the four last years. He found that during the last period there were fewer deaths than the average of the entire four years, and so, evidently according to our statistics, while there was no increase in the total deaths from pneumonia, still, when they compared the results by the different ages, they found an increase in those under 5 years of age. There were more pneumonia deaths during the last period than the average for the four years. During the first period, November and December, 1899, and January, February and March, 1900, there were quite as many deaths from pneumonia in Indiana as during the same periods in 1903 and 1904. The weather of the last period was very bad, being very raw, cold and wet. The humidity was high. In the first period there were quite as many pneumonia deaths, but the weather was comparatively mild, so he concluded that the weather was not causing an increase, if there was an increase, which did not appear by these comparisons. In one particular the two periods were alike in having the same number of deaths from pneumonia and in this, that measles, influenza and whooping cough prevailed extraordinarily in both those periods, and in the lower periods they did not prevail, but Dr. Hurty could not find any similarity in the weather to account for it.

Dr. Henry B. Baker, Lansing, Mich., stated that from his standpoint the method of study is fundamentally wrong. He does not think we know from that method of study whether pneumonia is increasing or decreasing. It is not a satisfactory method to determine this question by means of the ratio of deaths from pneumonia to the deaths from all causes, because the deaths from the other causes are changing. Dr. Fulton or someone should take these figures and give us the relation of the deaths from pneumonia at certain ages to the population at those same ages. We are indebted to Dr. Fulton for calling attention to the influence of these other questions on the subject, but it is too early to apply these corrections which he seeks to apply. We haven't anything to apply them to to the best advantage.

Dr. Benjamin Lee, Philadelphia, believes that a board of health without a proper system of registration of vital statistics is a truncated animal, and he is simply longing for the time when Pennsylvania will take as firm a stand as any other state. There are one or two points in regard to this question of pneumonia which have not been touched on. One is the influence of the presence in this country for the past ten years of the grip germ. Unquestionably a great many of the cases reported as pneumonia take that special form. The other point is the greater prevalence of pneumonia in cities as compared with the rural districts. Dr. Lee believes that street dust is a great factor in producing the disease, and whether that street dust contains the pneumococci or whether it contains some other poison is in each case an open question. He believes that long periods of dry weather, during which the atmosphere becomes filled with dust, are more frequently a source of danger than rainy weather. A most interesting experiment was tried in the city of New York many years ago. They were laying out a large park and had set out a great number of elm trees, and during the first two years all those trees died. When they came to take up the trees to find out the cause of death they found that all the roots of the trees were dyed blue, and on investigation they discovered that the dye material was Prussian blue, produced by the reaction of iron, potash and nitrogenous material in the street dirt, which had been used as a fertilizer. Dr. Lee has never followed up the question as to what effect the breathing of dust laden with Prussian blue would have, but he can conceive that it would have a very unpleasant action on the mucous membrane of the air passages. He does not believe that the question of street dust is at all ended when we talk only about the bacilli. He believes that there are other impurities and poisons in the street dust which may affect the pulmonary tissues disastrously.

Dr. G. T. Swarts, Providence, R. I., stated that the changes in nomenclature have been so rapid within the last four or five years that it would be difficult to compare the results with previous years. One could hardly believe the conditions existed as they are reported, and with the intent of learning something of those conditions since last February he has written to every physician who has reported the cause of death as pneumonia as to whether there was any known exposure to another case. That was for the purpose of determining if boards of health could profit by requiring isolation. At the present time it would seem that the amount of known exposure is very slight indeed. In answer to his inquiries he noticed that sometimes a physician would correct his diagnosis and state that the attack of pneumonia followed influenza. That would lead us to go back to what we call the primal cause of pneumonia, and whether the pneumococcus was present or some other organism as in measles or scarlet fever, and which has produced the inflammation of the lungs which simulates pneumonia. Until we can educate physicians to make an exact diagnosis and be more particular as to what we, as registrars, desire from them our statistics will still be in a chaotic state. When we attempt to draw conclusions we are very apt to be led astray unless we know the physician. The physicians of the state of Rhode Island are taking up this subject with interest, especially as they have been pestered for the last few years with questions from the registrar as to what they mean or do not mean to give as the cause of death.

Dr. John S. Fulton said that this subject, like many others of the sort, is in a state of confusion. To show that was one of the purposes of the paper. The argument which he made is for the most part destructive, but is none the less a necessary argument. The registration offices in this country do not furnish the data necessary to a satisfactory study of the subject. Accurate numerical statements concerning the elements of population and concerning the distribution of mortality are lacking. The heterogeneousness of some of the mortality accounts has not been sufficiently considered by many students of the subject, and some registration offices have published misleading and alarming statements based on very insufficient data. The influence of improving diagnosis has not been accorded its due importance and the history of indefinite causes of death has not been taken into account. To his mind one of the most interesting phases of mortality registration is its progress toward definiteness. As medical knowledge improves the indefinite account loses by the medical reference of a certain number of deaths to their true cause. At the same time the indefinite account gains by the statistical reference of deaths medically returned under very vague or obsolete nosological heads. The weight of movement is toward definiteness but some of our growing accounts have not become definite, and one or two, though having very definite appearing titles, such as pneumonia, have actually become less definite. The progressive unloading of the "unknown" account, of "teething" and "worms," "old age," "convulsions," etc., into other accounts gives as a general result an exaggerated view of rising accounts and a disguise of falling accounts, but no one dare say, without careful examination, how any particular account has been affected. The pneumonia account has received substantial accretions from certain more indefinite accounts, but the term pneumonia has not meanwhile grown more definite, but less so. No one is prepared to tell us exactly what the pneumonia account includes, but in the period of life below 5 years 85 per cent. of the pneumonia mortality consists of the secondary bronchopneumonias, having a variety of etiologic relations. In the present state of knowledge it matters little that the pneumococcus is more or less loosely related to many of these cases, for the relations of pneumococcus even to the massive pneumonias, which physicians have in mind when speaking of pneumonia, are not yet satisfactorily affirmed. A consideration of the figures seems to Dr. Fulton to suggest rather strongly that about 1889 a new factor entered into the pneumonia mortality of young children. This new factor may not have been the freshly imported strain of influenzal virus, but it certainly was not a new strain of pneumococcus. The relation of influenza to infant mortality has not been regarded as very important, but he suspects that the apparent pneumonia mortality would be very much reduced by successful prophylaxis of influenza, and that profits therefrom would be realized most amply by that part of the population under 5 years of age.

THE MANAGEMENT OF HERNIA IN INFANCY AND CHILDHOOD, WITH RESULTS OF OPERATIVE TREATMENT.*

WILLIAM B. COLEY, M.D.

Surgeon to the General Memorial Hospital: Associate Surgeon to the Hospital for Ruptured and Crippled.

NEW YORK CITY.

The fact that at least one-third of all the cases of hernia occur in children under the age of 14 is sufficient evidence of the importance of this subject.

Most cases of hernia in infancy and childhood are regarded as congenital, but this is a term that has given rise to much confusion. By congenital hernia we do not mean a hernia that existed at birth, but a hernia due to the failure on the part of Nature to close the process of peritoneum that has followed the testis in its descent into the scrotum. If the hernial sac is found at operation to communicate with the tunica vaginalis of the testis, we speak of it as congenital hernia. If, however, the pouch of peritoneum has become closed off just above the testis, but still leaving an open funicular process extending through the canal, or even into the scrotum, we still have a condition quite as favorable for the development of a hernia as in the former typical congenital variety. This latter variety, strictly speaking, would be a congenital hernia, although there is no way of differentiating it, anatomically, from an acquired hernia.

It is probable that the great majority of herniæ in children under the age of 5 or 6 years belong to these two varieties, and owe their existence to a congenital or preformed hernial sac. An analysis of our own series of operations for hernia in children shows that in more than half of the cases there is no communication between the hernial sac and the tunica vaginalis. Given the existence of a congenital or pre-formed sac, the immediate or exciting cause may be anything that greatly increases the intra-abdominal pressure, e. g., crying, coughing, straining at stool, constriction of the abdominal cavity by too tight bands.

The main question under consideration in the present paper is how to treat a hernia after it has developed, and the first point to decide is: Shall the treatment be mechanical or operative?

We believe that truss treatment should always be the method of choice in children under the age of 4 years, although not a few surgeons, both here and abroad, are now advocating operation as the primary method of treatment in infants. While I believe it a good general rule not to operate until the age of 4 years has been reached, there are certain important exceptions:

1. If there is a history of strangulation that has become reduced by taxis, I believe that an operation is indicated, no matter how young the child.

2. In cases in which, despite carefully directed truss treatment, the hernia has become irreducible, or reducible with difficulty, I think early operation should be advised.

3. In cases in which the rupture can not be controlled by a truss and, as a consequence, is gradually increasing in size.

4. In all cases of femoral hernia, the reason for prompt operation in this class being that a cure by persistent truss treatment is practically unknown at any age.

5. Immediate operation is indicated in all cases of hernia associated with reducible hydrocele or fluid in the hernial sac, inasmuch as it is impossible to control the rupture by means of a truss, and there is, hence, nothing to be gained by waiting.

RESULTS OF MECHANICAL TREATMENT IN CHILDREN.

Roughly speaking, I believe that herniæ in infants and children under the age of 4 years can be cured by carefully directed truss treatment in about two-thirds of the cases, although it is probable that, in after years, a considerable percentage will relapse.

Beyond the age of 4 years, in a fair proportion of the cases, a cure can be effected by means of a truss, provided the truss is properly fitted in the first place, and the child is regularly seen by a surgeon for a period of not less than two years.

METHOD OF MECHANICAL TREATMENT.

There are several kinds of trusses, all of which are of nearly equal value in the treatment of hernia in children. Personally, I consider the "opposite-side" or "cross-body" truss (Knight truss, Fig. 1) the best. It consists of a light steel frame, extending three-quarters the distance around the pelvis, the remaining distance being covered by a strap. The spring is covered with rubber tubing, and the pad is attached to a short steel arm fastened at right angles to one end of the spring. The spring is so tempered that any desired pressure can be easily secured. Another very good form of truss is the frame truss of the Hood or Pomeroy type (Fig. 2).

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

A truss can not be applied too early. As soon as a rupture in an infant has been recognized, the truss should be immediately fitted and should be worn night and day.

Umbilical hernia in children generally develops during the first year of life, and in the great majority of cases can be cured by mechanical treatment. Operation is very seldom indicated. One of the best methods of treatment in these cases is by means of a small wooden button mold, covered with rubber plaster and placed over the opening. This pad is held in place by a circular strap of rubber plaster, two inches in width, entirely surrounding the abdomen. Care should be exercised not to cause any appreciable constriction. This should be changed every week or ten days. In rare cases with very large opening, the hernia may be found to persist despite careful treatment. In these cases operation should be performed. The method of excision of the umbilicus, including the hernial sac, with careful suture in three layers—with or without overlapping the fascia—will almost always result in a permanent cure.

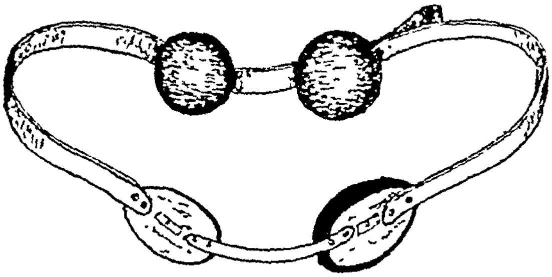

Fig 1.—"Hood" or "Pomeroy" truss

Epigastric herniæ are not very rare in children, and if the opening is large enough to admit the tip of the index finger an operation will probably be needed to effect a cure. They do not tend to spontaneous cure, as is generally the case in umbilical hernia in children.

DURATION OF TREATMENT.

If a child has reached the age of 4 years and the rupture has not been cured, as shown by its occasional appearance when the truss is removed, then an operation should be performed. If a rupture is first noticed in a child over 4 years of age, it is a question whether to employ mechanical or operative treatment. At this age the percentage of cures by truss treatment is comparatively small, far less than in infants. In addition, the treatment, in order to be of any avail, has to be prolonged over a period of from two to three years which, to a dispensary child, means a great deal of trouble and much loss of time to the parents in bringing the child regularly to the hospital or dispensary. Hence there is much to be said in favor of an operation, which is practically sure to effect a cure in from two to three weeks' time, and, furthermore, is almost entirely free from risk. It has been our former practice at the Hospital for Ruptured and Crippled to treat all children with comparatively small and easily held ruptures for a time with a truss. However, of late the results of operation have been so uniformly satisfactory that we are now inclined to advise operation in the majority of such cases, especially in dispensary children, who seldom get proper supervision of the truss at home.

METHODS OF OPERATION.

It seems to be the impression that the radical cure of hernia in children is a much simpler matter than in adults, and that almost any method will accomplish the desired result. While it may be admitted that the results of operation in children during the past decade have been a trifle superior to those obtained in adults, I believe this fact due rather to improved methods of operation than anything else. I need only cite a series of 20 cases operated on at the Hospital for Ruptured and Crippled prior to 1890 by the methods of Socin and Czerny, with 50 per cent. of relapses in less than a year after operation, to disprove the contention that hernia in children can be cured by any method of operation.

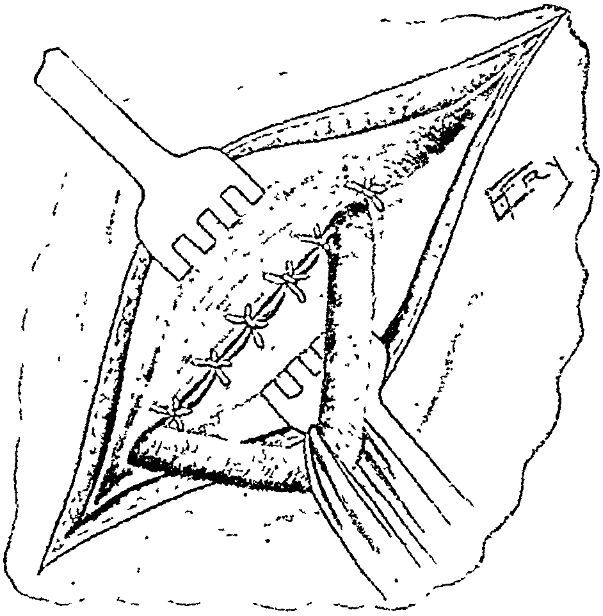

Fig. 2.—Bassini's operation (deep sutures), showing extra suture above the cord.

To operate in children in which we have to separate the hernial sac, as thin as tissue paper, and avoid cutting or tearing the slender cord, requires far more care and delicacy than the operation in the adult. With the operation carefully and skillfully done by the Bassini method, or possibly by the same method without the transplantation of the cord, the results are almost perfect.

I have as yet never cut or torn the cord, either in children or adults, and with proper care the accident should never occur. The lower end of the sac is removed if acquired, and if congenital, i. e., communicating with the tunica vaginalis, I always put in a purse-string suture which closes it over the testis.

I believe the substitution of an absorbable suture, e.g., chromicized kangaroo tendon, a great improvement over the buried silk sutures advocated by Bassini, or the silver wire so much used and lauded by other surgeons.

The method of operation that I have employed in most cases in children as well as in adults, is the Bassini method, with the modification of first placing one suture above the cord, in addition to those below, to prevent any widening of the new internal ring in an upward direction, and to substitute for the buried silk sutures used by Bassini absorbable sutures. i. e., chromicized kangaroo tendon.

After the sac has been tied off well beyond the neck, at a point where it has begun to widen out into the general peritoneal cavity, the deep layer of sutures is placed as follows: With a small tape the cord is held up and the first suture is placed so that it just touches the lower border of the cord when the latter is brought vertically to the plane of the abdomen; three to four more through the internal oblique and Poupart's ligament will suffice to close the canal to the symphysis pubis. Then the suture above the cord (Fig. 3) is inserted. This is not a part of Bassini's technic, but I believe it is of decided aid in preventing a relapse, as it strengthens the only weak point in the operation. The incision in the aponeurosis is then closed from above downward by a small continuous suture of kangaroo tendon and the skin with catgut. No drainage is used, and the wound is dressed very carefully with sterile gauze, cotton, a firmly applied spica bandage, and finally a plaster-of-paris spica is applied to give perfect rest to the parts. The wound is dressed the seventh day, and the patients are kept in bed two weeks and allowed to go out in from two and one-half to three weeks, wearing a spica bandage until four weeks have elapsed, after which time no support is worn.

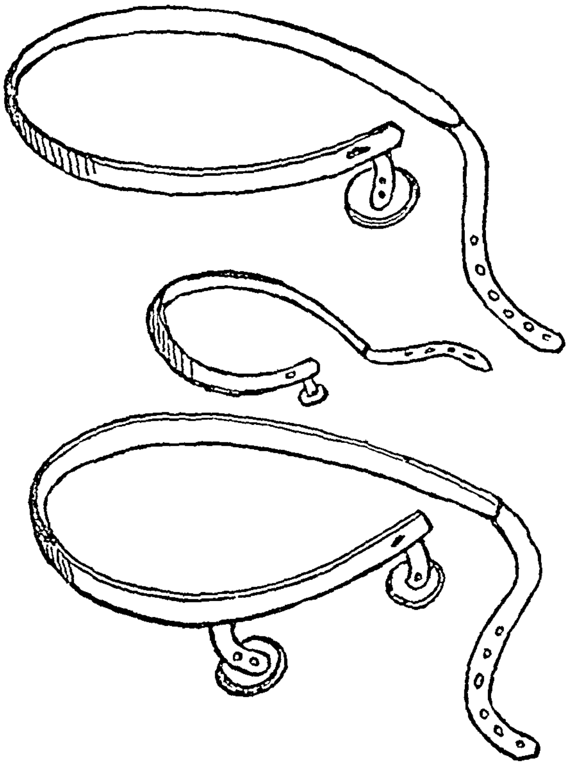

Fig. 3.—The "Knight" truss; single and double.

In a small series of cases, about 100 in number, extending back to 1892, Dr. Bull and myself have employed a method practically the same as Bassini's, without transplantation of the cord, the cord coming out at the lower angle of the wound, just above the symphysis pubis, the internal oblique being sutured to Poupart's ligament, the aponeurosis of the external oblique closed by continuous suture. In other words, all the steps are identical with those of Bassini's method, except the treatment of the cord.

This is the method that has recently been advocated by a number of surgeons as superior to Bassini's, and while they have perhaps operated on a larger number of cases by this method, these cases have not been observed for so long a period as our own. The method is undoubtedly an excellent one, but the results, as far as I have been able to determine from present data, are slightly inferior to those obtained with transplantation of the cord. There has been no atrophy of the testis following the transplantation of the cord, and the time required for the operation, with or without the transplanting of the cord, is practically the same, viz., from ten to fifteen minutes.

I have personally operated on 230 cases of inguinal hernia in the female, including both children and adults, by this method, namely, allowing the round ligament to come out at the lower angle of the wound instead of removing or transplanting it; suture of the internal oblique to Poupart's ligament, and closing the aponeurosis by a continuous layer suture of kangaroo tendon. These 230 cases have been very carefully traced, and, thus far, not a single relapse has been observed.

These results, while they go far to prove that the transplantation of the round ligament is neither necessary nor desirable, do not to the same extent prove the uselessness of the transplantation of the cord in the male, inasmuch as the cord is considerably larger than the round ligament, especially in the region of the symphysis pubis, or at the point where it emerges from the external ring. Removal of the veins of the cord is never necessary in children, and personally I believe it is very seldom indicated in adults.

COMPLICATIONS—HERNIA ASSOCIATED WITH UNDESCENDED TESTIS.

This condition is not infrequent in hernia in children, and there is by no means unanimity of opinion among surgeons as to its proper treatment. Some advise against operation altogether until the age of puberty; others advocate operation in all cases, even in infants.

Truss treatment of hernia, associated with undescended testis, is most unsatisfactory. The pad presses on the testis and causes pain, and may keep the testis within the external ring and retard its natural progress into the scrotum. The danger of producing malignant disease from the pressure of the truss on an undescended testis is far less than one would believe from the prominence given it in surgical text-books. Such a result has never been observed at the Hospital for Ruptured and Crippled during the last fourteen years, during which time upward of 60,000 cases have been treated.

McAdams Eccles of London, in his very elaborate study of the subject of undescended testis, shows that there is little foundation for this well-established belief. He states that in 48,000 males with hernia, 854 had undescended testis, and not a single case of sarcoma was observed.[1]

Bevan, in his admirable article[2] on the treatment of undescended testis, read before this Association a year ago, advises operation in most cases, even in young children.

I have operated on 38 cases of hernia associated with undescended testis, 27 of these being under the age of 14. At the Hospital for Ruptured and Crippled we were at first inclined not to operate under the age of 10 or 12, because observation showed that in many cases the testis descended into the scrotum of its own accord before the age of puberty. The danger of strangulation in these cases, even if a truss is not worn, is not great, as the testis acts as a barrier and prevents the rupture from coming down. Still, we have since found that even if the testis does descend into the scrotum, the hernia, as a rule, persists, and operation is finally necessary. For this reason we are now operating earlier than formerly.

---

[1] Since this was written I have just observed for the first time a case of sarcoma of an undescended testis in a man of 35. The patient, however, never wore a truss. In my series of 22 cases of sarcoma of the testicle this is the only one in which the testis was undescended.

[2] THE JOURNAL A. M. A., Sept. 19, 1903.

METHOD OF OPERATION FOR HERNIA ASSOCIATED WITH UNDESCENDED TESTIS.

The Bassini method has been employed in most of my cases, but a little gain in the length of the cord is secured if it is not transplanted, and as the results are so nearly equal, I think it is well to omit transplantation in such cases and let the cord emerge at the lower angle of the wound. By freeing the cord very high up and by removing some of the veins, if necessary, the testis can, in most cases, be brought into the scrotum. In my early operations I tried several methods of fas*tening the testis into the scrotum, e. g., by wire frames*, but soon abandoned such methods. If the testis is to remain permanently in the scrotum, it must be so thoroughly freed from the cord that it rests in the scrotum without tension, otherwise it will finally retract to the external ring or into the canal.

I believe that the method proposed by Bevan, of separating the veins deeply in the iliac fossa with the finger, is attended with some risk, and a hemorrhage in such a place would be most difficult to control. I do not believe the testicle should be sacrificed, for the reason that, although atrophied and possibly of little functional value, it nevertheless has an important influence on the development of the child. The hernia can certainly be cured without castration, as is shown by our own statistics. In no case has the hernia relapsed.

In the earlier cases in which less care was taken to thoroughly separate the fascia and free the cord high up, retraction of the testis to the region of the external ring was the rule rather than the exception. In the more recent cases it has been found possible, in a greater proportion of cases, to keep the testis in the scrotum.

STRANGULATED HERNIA IN CHILDREN.

This condition is comparatively rare in children, and is most frequent during the first two years of life. I have operated on 13 cases between the ages of 13 days and 14 years. In only 2 cases did strangulation occur between the ages of 2 and 14. This series of cases helps to settle an important and much-disputed point in the etiology of strangulation in children. The earlier statistics stated that the neck of the sac caused the strangulation in most cases. In every one of my own cases the strangulation was due to the tense fascia of the external ring, and not to the neck of the sac, which, in children, is always a thin and easily distensible membrane, incapable of producing strangulation. The error of the older statistics is probably due to the fact that operation in these cases consisted in merely relieving the strangulation by cutting all the tense tissues, including the sac at the same time. Hence the particular tissue causing the strangulation was not recognized. In our own cases the operation is precisely the same as that employed for the radical cure of non-strangulated cases, the skin incision being made beginning on a level with the anterior superior spine, and there has never been any difficulty about the reduction of the strangulated loop of bowel as soon as the tense fascia of the external ring has been severed.

In the 12 cases of strangulation there was one death, in a child six weeks old, the hernia having been strangulated for three days, and the child practically moribund at the time of operation.

RESULTS AS REGARDS PRIMARY WOUND HEALING.

Prior to 1897, when rubber gloves were not used, primary wound healing was observed in 96 per cent. of the cases; since the introduction of rubber gloves, it was noted in 99 per cent., which proves beyond any question that it is possible to obtain a sterile absorbable suture. Furthermore, the fact that the final results in 775 Bassini operations in children showed but three relapses, proves quite as conclusively that the tendon sutures remain unabsorbed sufficiently long to effect a permanent cure. The disadvantages of using buried nonabsorbable sutures in the hernial canal I have pointed out so frequently that I will merely allude to them here.

In a certain number of cases they lead to the formation of a sinus, which usually persists for weeks or months, until the offending suture is removed, but the worst feature is the weakening of the canal by the suppuration, leading in most cases to relapse. A large number of such cases have been observed at the Hospital for Ruptured and Crippled, showing that these objections are not merely theoretical, but very practical.

FINAL RESULTS OF OPERATIVE TREATMENT.

Between August, 1891, and July, 1904, I have performed 825 operations for the radical cure of hernia in children under the age of 14 years with one death, due to ether pneumonia. Four operations were for umbilical hernia; four for ventral; two for epigastric; 25 for femoral; thus making 815 cases for the radical cure of inguinal and femoral hernia in children; or 790 operations for inguinal hernia. In 15 of these the cord was not transplanted, leaving 775 cases in which Bassini's method, with the substitution of chromicized kangaroo tendon for the buried sutures, was performed. In this series of 775 operations but 3 relapses were observed; in the 15 in which the cord was not transplanted, 5 relapses were noted.

In a total of 1,330 operations for the radical cure of inguinal and femoral hernia, including adults, only two deaths occurred, and 12 relapses.

In the 25 cases of femoral hernia in children, there has not been a single relapse. Sixteen were examined and found perfectly sound from 3 to 8 years after operation; 5 from 1 to 2 years; four cases were not traced beyond six months.

The utmost effort has been made to trace these cases to final results, and comparatively few have been lost sight of. In my paper read before the American Surgical Association[3] a year ago, the end results of 1,003 cases were given in more detail. Six hundred and fifty of these cases (including adults) were examined and found perfectly sound from 1 to 11 years after operation.

The method of operation for femoral hernia in children has been in every case the "purse-string suture," with kangaroo tendon.

The technic, as I have performed the operation, in brief is, first, to thoroughly free the sac well beyond the neck; high ligation of the sac and closure of the canal by means of a purse-string suture of chromicized kangaroo tendon. The suture is introduced through Poupart's *ligament or the inner portion of the roof of the* canal, or crural arch, from where it passes downward into the pectineal muscle or floor of the canal, outward through the fascia lata overlying the femoral vein, and upward through Poupart's ligament or roof of the canal, emerging about three-fourths of an inch from the point of introduction. On tying the suture, the floor of the canal is brought into apposition with the roof, and the femoral opening is completely obliterated. The superficial fascia may then be closed with catgut or fine tendon, and the skin either with catgut or silk.

---

[3] Transactions of the Am. Surg. Association, 1903; Annals of Surgery, June, 1903.

This method I believe superior to Bassini's operation for femoral hernia, and of 82 operations for femoral hernia done within the last 14 years, 66 were performed by this method, without a single relapse; in 16 cases operated on by Bassini's method, there was one relapse.

RELAPSES AFTER BASSINI'S OPERATION FOR INGUINAL HERNIA IN CHILDREN.

1. J. K., male, aged 6½. Bassini's operation, substituting kangaroo tendon for silk in the buried sutures, done in October, 1894. Primary wound healing. Slight relapse one year later.
2. J. W., male, aged 9. Operated on by Bassini's method in August, 1894. Slight relapse two years later. Truss applied for a time; then left off. Examination in 1903, nine years later, showed only a slight impulse on coughing.
3. B. B., aged 6. Right inguinal hernia. Operated on June 12, 1903. Wound healed by primary union. On July 15 the patient had a severe attack of whooping cough, during which time he applied no support to the recently healed wound of the inguinal canal. A recurrence was noticed on August 8.

RELAPSES IN CASES IN WHICH THE CORD WAS NOT TRANSPLANTED

1. H. O., aged 8. Operation Dec. 12, 1901. Cord not transplanted. Relapse three months after operation.
2. C. R., aged 13. Very large right inguinal hernia. Operation Dec. 28, 1891. Cord not transplanted. Silk used for the deep buried sutures. Wound suppurated and most of the deep sutures came out. Relapse within three months after operation.
3. B. S., aged 12. Right inguinal hernia. Operation January, 1892. Cord not transplanted. Silk used for the buried sutures. The wound healed by primary union, but a few weeks later a sinus formed and a few silk sutures were extruded. Relapse followed a few months later. Patient was re-operated on by Bassini's method, and was entirely well ten years after.
4. F. H., aged 10. Operation February, 1892. Cord not transplanted. Chromicized catgut for buried sutures. Patient remained well for three years, when a slight relapse occurred.
5. E. B., aged 6. Operation February, 1901. Cord not transplanted. Sliding cecal hernia. Relapse three months after operation.

REMARKS.

A closer study of these relapses is of some interest. In four of the five relapses following operation without transplantation of the cord, operation was performed in 1891-2, or more than twelve years ago. In two of these cases silk was used for the buried sutures, with subsequent sinus formation which weakened the canal and was, undoubtedly, an important factor in causing the relapse. In the fifth case which relapsed after operation in 1901, we had to deal with a sliding cecal hernia, a form of rupture the radical cure of which is acknowledged to be almost impossible to obtain with any method of operation. Five relapses in a series of twelve cases in which the cord was not transplanted is certainly a high percentage.

Coming to the cases operated on by Bassini's method with the substitution of kangaroo tendon for silk, in the buried sutures, we have 775 cases with three relapses. Two of these relapses were very slight; one of them showing only a moderate impulse on coughing nine years after operation. The third was due to a severe attack of whooping cough coming on four weeks after operation.

This series of cases, I think, conclusively proves that the risk of operation for the radical cure of hernia in children is exceedingly small and the chance of securing a permanent cure almost certain.

DISCUSSION.

Dr. David E. English, Millburn, N. J., stated that some years ago he emphasized the fact that in the treatment of this form of hernia a proper kind of pad must be used and that anything in the shape of a button that was pointed or round on the surface next to the skin would rather defeat the purpose for which it was placed there. Since reading that paper he has used a silver quarter, properly padded, and his results have been very good.

Dr. Arthur L. Fisk, New York City, agreed with Dr. Coley that it is not wise to operate on such young infants unless the conditions demand it.

Dr. Rosa Engelmann, Chicago, asked Dr. Coley how he prevents excoriation of the skin in connection with his applications for the treatment of ventral hernia. Recently Dr. Engelmann has been using the oxid of zinc plaster, and still has been unable to prevent excoriation of the skin.

Dr. W. B. Coley, in reply to questions, said that the character of the pad in ventral and umbilical herniæ is of considerable importance. The side in contact with the skin should be slightly convex instead of concave, and should be considerably larger than the hernial ring, since otherwise it will sink into the ring. A certain amount of excoriation will be produced by any kind of plaster if it is allowed to remain on for any length of time, but zinc oxid has been found to cause far less trouble than the ordinary plaster. It should always be changed within a week or ten days, and strict cleanliness should be observed. Dr. Coley agreed with Dr. Fisk that it is not wise to operate on very young infants, although there is a great tendency, particularly in France and Germany, to operate on infants even a few months old. The fact that so many of these cases can be cured by the use of a truss and, furthermore, that the danger of strangulation in infants is not great, are ample reasons for deferring operation.

THE SCHOTT METHOD OF TREATING DISEASES OF THE HEART AND BLOOD VESSELS.*

JAMES M. ANDERS, M.D., LL.D.
PHILADELPHIA.

It may appear rather late in the day either to present the claims of the Schott methods of treating chronic cardio-vascular diseases or to discuss the details connected with their application. It should ever be a feature of our therapeutic creed, however, to give close attention to physiologic means and to recognize their superiority over drugs as curative agencies. No one who views the immense concourse of persons pouring into Bad Nauheim from every part of the globe and notes the conditions presented by a small fragment even, as I have done, can fail to be impressed with the fact that confusion obviously reigns in the minds of a large proportion of the medical profession as to what constitutes a suitable case for this recognized mode of treatment. The same vagueness and indefiniteness of professional thought and action holds true at home, perhaps in greater degree than abroad, more especially in England, Germany and Russia—countries in which much attention has been paid to the subject. These facts furnish the *raison d'être* for attempting to extend a knowledge of the subject among the members of the profession of America, on whom it unquestionably has strong claims. On the other hand, the Schott method of treating chronic cardiac diseases has not been as universally appreciated as it deserves. A transference of the point of view to an actual observance of the workings of the *kur* furnishes a clearer vision and serves to emphasize both its efficacy and the vastness of its sphere of usefulness.

---

* Read at a meeting of the Philadelphia County Medical Society, 1904.

Of the numerous health resorts that have risen to fame in recent times, unquestionably Bad Nauheim heads the list, but its claims to public favor are not solely ascribable to the virtues of its healing waters as some contend, great as is the value of this expedient, but, as will be shown hereafter, the "resistance exercises," which enter into the method of treatment herein described, form an element of almost equal therapeutic importance. Considerable attention is also bestowed on the patients' dietary and hours for sleep and recumbency. Again, Nauheim has certain outside recommendations, and commands an attractive and restful environment. Beautifully embowered in a pretty park, lying near the foot of the Tannus mountain, are the commodious, cheerful and modern bath-houses (*bäder*), while the springs, or underground streams, that supply them "without hurry and without rest," gracefully yield their healing waters from the great repositories of Nature. Around this fairly extensive and pretty park cluster numerous stately villas, hotels, and, in the loftiest part stands prominently the handsome "kurhaus," on the terrace of which there are daily concerts by an orchestra, and theatrical performances in the evening, the amusements offered being in keeping with the nature of a serious health resort.

One need not renounce modern comfort at Bad Nauheim. I gained the impression, however, that the healthy public might find this resort dull, since conversation constantly involves excursions into the subject of chronic diseases of the heart and their treatment by the special method under consideration. This resort possesses certain minor climatic advantages; it is situated on the edge of a plateau (the Wetterau) at an elevation of 450 feet above the level of the sea, and the nights are always cool, owing to the nearness of the Johannisburg and the Woodland. There are also long, wide avenues with their cooling shade. Again, the sanitary arrangements are quite good.

In attempting to present the claims of the Schott methods of treatment of chronic cardiac diseases, as conducted at Nauheim, I am not unmindful of the existence of the excellent monograph of Bezly Thorne[1] and the papers published on the subject by Camac,[2] Tyson,[3] Baldwin[4] and others. These writers have given a creditable estimate of its advantages and have fully presented the details of its application, but they have scarcely formulated the whole truth in the premises. Moreover, the skeptically minded is among us; he who ascribes the *rationale* of the phenomenal results achieved to the good effects of rest and a peculiarly attractive environment. Granted that a salubrious environment shares in the production of the beneficial effects, the principal and most influential factors to the attentive and practiced observer are unquestionably the systematic and methodic use of the saline baths and the "resistance movements."

Time and space forbid a full descriptive account of the baths and their constituents in this place. The springs are known both by names and numbers, but the former alone will best serve the purposes of this article.

The bath waters contain from 2 to 3 per cent. of sodium chlorid, from 2 to 3 per 1,000 of calcium chlorid, various forms of iron, and above all, a large amount of carbonic dioxid (Schott).[5] A course of baths embraces the use of waters of various strengths, ranging from the milder to the more potent with the progress of the cure, and the duration of the period of immersion is also variable. At the beginning, the waters of the so-called thermal baths are employed; they are freed to a certain extent from their natural gas. These are succeeded by the thermal-sprudel baths, then pure sprudel and, finally, in a certain proportion of the cases, the so-called strom-sprudel. The baths intermediary between the thermal and effervescing (sprudel) are supplied from storage tanks. To render the baths more stimulating, so-called *"mutterlauge,"* which is the refuse of the salt manufactory in the neighborhood, is added in carefully increasing quantity in certain cases. The flowing sprudel (strom-sprudel) baths, which possess the greatest balneologic strength known, are most efficacious when judiciously and wisely employed. Here the waters of the principal springs forcibly enter, pass through and leave the bathtub during the period of immersion; it is the "bath of champagne."

It can be readily shown that the Nauheim waters offer more than simple saline baths, seeing that they contain carbon dioxid in solution and are also strongly ferruginous. Furthermore, the amount of carbon dioxid is far greater than that contained in any other bath on the continent. The physiologic effects of the mineral baths are at present writing fairly well understood, although at an earlier period of time they were used empirically as a remedy in rheumatism and later in chronic cardiac diseases. The baths exert a beneficial influence in various directions in cardiac insufficiency and prominent among the salient results are a more vigorous systole with diminution in the size of the dilated heart and a reduction of the pulse rate. The diminution in the size of the heart is readily established both by percussion and the use of the x-rays.[6]

Of equal importance is the influence exerted on the blood paths, by means of which there is accomplished an arteriodilatation and a transfer of the abnormally large increment of venous blood to the arterial side of the circulation. The blood pressure, as shown by Prof. T. Schott,[7] is generally raised, but when it is too low at the start, this effect is not observed.

It is especially noteworthy that in consequence of a freer coronary circulation the impaired nutrition of the myocardium is correspondingly benefited. The labor of the overburdened heart is greatly diminished and its recuperation to a like extent assisted. Indeed, as the result of personal observation, I am enabled to affirm that all the usual evidences of an impaired circulation presented by the different organs (lungs, liver, stomach, kidneys), as well as the anasarca, disappear as the heart's capacity for physiologic work augments under the influence of balneologic therapy.

[6] Med. Record, June 29, 1901.

[7] Among the most valuable early papers on the effects of the baths on the heart was that of A. Schott, published in 1880.

This effect on the circulatory system is not due to a direct action of the baths, but an indirect one through irritation of the cutaneous sensory nerve filaments, the stimulation being conveyed to the vasomotor, cardiac and other nerve centers, and producing an effect on the organic functions and general nutritive processes.

Beneke directed forcible attention to the striking improvement in comparison and even complete recuperation of enfeebled heart action in old valvular lesions, in gout and rheumatism, complicated with heart disease, as the result of *judicious employment* of the Nauheim springs. In 1882, the Brothers Schott began an exhaustive series of experiments on the effects of immersion in saline solutions on the blood pressure of lower animals. These experiments, together with those of Beneke and Jacob of Cudowa, place the fact beyond controversy that saline baths exert a marked influence on the blood pressure. Further, the "resistance movements," which are employed concurrently with the baths, were first introduced and elaborated by the Brothers Schott.

In this connection too much stress can not be placed on the rôle played by the nervous system in bringing about the curative effects of this special method of treatment. Thorne wisely argues that a certain amount of stored energy (available for response to the various stimuli which may be brought to bear on it) is necessary to a successful application of the therapeutic baths and "resistance exercises." It therefore requires an orderly method and sound judgment to decide whether or not the Schott methods are applicable to the given case, more especially if the patient is suffering from an advanced valvular lesion or myocardial degeneration.

The object of the "resistance exercises," which constitute the second essential portion of the Schott method, is to throw into activity different groups of muscles, more especially those of the extremities, "in orderly succession without inducing fatigue." The movements exert a marked influence on the circulation, both lesser and systemic. Indeed, *they do not belong to the domain* of "gymnastics," since they exercise their principal therapeutic effect over the cardiovascular system rather than over the muscular system. There has been considerable controversy over the *rationale* of the "resistance movements." Unquestionably they bring muscles that are *for the greater part inactive* under usual conditions, into normal functional activity; they stimulate the peripheral motor nerves, while the baths, it will be recollected, act on the sensory nerve filaments, and finally, they exert a tonic effect on the myocardium. The movements also *tend to drive the venous blood to the right side of* the heart, by compression of the veins (Broadbent).

This element of the treatment must be carried out by a specially trained operator, who carefully observes certain details in connection with its application. These rules are well summarized by Thorne as follows:

1. *Each movement is to* be performed slowly and evenly, that is, at a uniform rate. 2. No movement is to be repeated twice in succession in the same limb or group of muscles. 3. Each single or combined movement is to be followed by an interval of rest. 4. The movements are not to be *allowed to accelerate* the patient's breathing, and the operator must watch the face for the slightest indications of (*a*) dilation of the alæ nasi, (*b*) drawing of the corners of the mouth, (*c*) duskiness or pallor of the cheeks and lips, (*d*) yawning, (*e*) sweating, and (*f*) palpitation. 5. The appearance of either of the above signs of distress should be the signal for immediately interrupting the movement in process of execution, and for either supporting the limb which is being moved, or allowing it to subside into a state of rest. 6. The patient must be directed to breathe regularly and uninterruptedly, and should he find any difficulty in doing so, he must be instructed to continue counting, in a whisper, during the progress of each movement. 7. No limb or portion of the body of the patient is to be so constricted as to compress the vessels and check the flow of blood.

Every *movement is designed to achieve* a practical result on physiologic principles. The patient's condition and endurance must be the criterion as regards the number and character of the movements to be employed. In all cases, therefore, the physician must carefully instruct the operator; not only so, but he should *supervise the administration of the "resistance movements"* until convinced that they are being properly executed. It is not less important for the medical attendant to note the effects of the movements, for while, as a rule, the circulatory organs, and to a lesser extent the muscles and respiration, are strengthened and invigorated, yet an imperative need for a modification of the method may be presented. The movements employed are accurately and individually described by Bezly Thorne, and the reader may be referred to his excellent work for further details.

Much in this position might be said to further elucidate the physiologic conditions involved in the more or less co-ordinate action of the two main elements of the Schott method, to-wit: saline baths and "resistance movements," but this course would require more lines than these to which I am limited. After all, it is through its marvelous effects that it makes the strongest appeal to the judgment of an unprejudiced observer. It is well known how unsatisfactorily and incompletely disturbances of compensation in the course of chronic valvular lesions yield to medicinal measures, rest and regulation of the diet at home, both in private and hospital practice; also that, almost with certainty, progressive myocardial degeneration advances, leading sooner or later to a fatal degree of dilatation under similar treatment.

On the other hand, I have recently witnessed the application of the method under consideration in chronic valvulitis and various other conditions at Nauheim, and convincing clinical evidence was afforded of its remarkably beneficial and curative effects in a variety of cardiovascular degenerations. Speaking generally, it seemed to me that the improvement, in the vascular changes, as shown by the increased lumen of the vessels and volume of the pulse, was quite as striking as that produced on the myocardial changes. And the yielding of cases of angina pectoris within a comparatively *brief period* of time would lend support to the assumption that many examples of this grave disorder are most probably dependent on abnormal vasomotor influence.

There was, however, brought to my attention clear evidence of the beneficial effects of the *method in vascular degenerations* of well-marked degree. The great advantages of the baths and exercises in these cases, as well as in myocardial changes, serve to emphasize their potency in stimulating or favorably influencing bodily metabolism. This statement granted, and *it becomes* needless to point out that the methods are applicable to a wide range of varying conditions other than cardiac.

I shall now choose a few illustrations from among a large number of different forms of cardiac and non-cardiac conditions which, by the courtesy of Prof. T. Schott, I had an opportunity of observing during the bathing course.

Case 1.—Mr. A. C., aged 28 years, married; occupation, auctioneer; height, 5 feet 11 inches; weight, 151 pounds (in clothes); no heart lesions in any member of his family; neither gout nor rheumatism furnished by the family history.

History.—Patient had had childish diseases; at 12 he suffered from rheumatic fever of a severe type, but no heart complications arose, so far as the patient's knowledge extends; he had been considered a good risk by life insurance companies up to 4 years ago. At 22 he contracted syphilis, for which he was vigorously treated, and neither secondary nor tertiary manifestations put in an appearance. Within the last 5 years he has had two mild attacks of influenza. The social history does not furnish many points, although the patient formerly smoked an average of from 8 to 10 cigarettes daily, and used from 3 to 4 drinks of whisky and soda in the same period.

Present Illness.—The present illness began 3 years ago while playing hard at polo, when he developed pain in the region of the heart, to relieve which a hypodermic injection of morphin was employed. Subsequently, he continued well for 18 months, with the exception of dyspnea on muscular exercise. One year ago he began to suffer from vertigo at intervals; his physician said the heart was enlarged on the left side. Artificial Nauheim baths were employed at the suggestion of Dr. Thorne. On July 4 the patient went to Nauheim; this was just 3 weeks before he fell under my personal observation. On arrival, vertigo recurred several times daily, dyspnea was marked and sharp pains through the heart were complained of; the bodily surface was everywhere cold to the touch. After 3 weeks' treatment, or at the time I first examined the patient, the vertigo had disappeared and dyspnea greatly lessened. He could now walk a distance of several squares, whereas he was unable to walk unaided at the time of his arrival at the springs.

Physical Signs.—August 1: Heart much dilated, to the left it extends to anterior axillary line, to the right to a point near the right edge of the sternum; the impulse is feeble and a slight presystolic-systolic thrill is detectable at the apex. The area of percussion dullness corresponds with the impulse, and on auscultation a faint presystolic-systolic murmur is audible at the apex. Some distance above, and near the left edge of the sternum, a pure diastolic murmur is heard; it is soft and blowing.

August 17: A second physical examination shows the border line of cardiac dullness on the left to correspond to vertical nipple line, and the right boundary falls ¼ inch to the left of the midsternal line. The murmur at the apex is not audible, although the second pulmonic sound is accentuated; the diastolic murmur is still heard. The heart sounds in general are much stronger than at the previous examination. The patient now indulges in long walks without noticeable dyspnea and denies any discomfort.

The case reported above was regarded primarily as one of acute dilatation; and although complete relief has been accomplished, the patient is urged by his attending physician, Prof. T. Schott, to return one year hence, meanwhile being allowed to resume his usual vocation.

Case 2.—W. A. M., aged 54 years; occupation, physician (lieutenant-colonel in the Indian medical service for 10 years); nothing hereditary in the family.

History.—Patient had had childish diseases, and syphilis at 20, attended with slight secondary manifestations only. Twelve years ago he had an attack of influenza and has not been in his usual health since. The patient had been a hard polo player for years, and also an excessive user of tobacco prior to the discovery of the heart lesions.

Present Illness.—In 1903 he had cold extremities and dyspnea on muscular exercise; Dr. Sansom diagnosticated mitral regurgitation with marked dilatation and instability of action.

Sept. 1, 1903: Patient commenced a course of treatment at Nauheim lasting 5 weeks; his condition was remarkably improved thereby, although sleepless and nervous for a time.

July 1, 1904: Symptoms returned to a moderate extent, and at once the patient proceeded to Nauheim. His condition was much less pronounced than in the previous year, and after a bathing course, lasting one month, I was privileged to examine him. There was present very slight dilatation of both ventricles; the increase in the transverse diameter of the heart being about ½ inch above the normal. The mitral systolic murmur was scarcely audible and the systole apparently normal; at intervals there was slight palpitation; it was not so apt to be induced by exercise as by nervous excitement, as on awakening or playing at a game of whist. The patient now indulged in long walks, even over mountain sides; this he could not do before the Schott method of treatment had been adopted.

It was supposed by his physician, Dr. Sansom, that the severe exercise and excessive use of tobacco had been the cause of the marked disturbance of compensation and induced secondary dilatation. It would appear from this and the previous case that the Schott methods are especially serviceable in the advanced stages of cases of rapidly developed dilatation. In confirmation of this position, I may state that Professor Schott related numerous cases of a similar character.

Case 3.—R. H., aged 38 years, single; occupation, practicing physician in New York City; height, 5 feet 7 inches; weight, 172 pounds (stripped). The family history is negative, except that his mother, who is living, has been afflicted with rheumatoid arthritis for 10 years, but only in the hands.

Previous History.—Absence of all childish diseases. While a medical student he had intussusception, which cured itself spontaneously. In 1896 he had typhoid fever, lasting about 6 weeks; this attack was of medium severity, but recovery quite slow. Two years later (meanwhile working), he noticed severe attacks of palpitation and dyspnea, and was easily fatigued, compelling him to curtail his work. During and after the attack of typhoid, he had attacks of hemicrania, now on one, then on the other side, and nausea always and vomiting sometimes occurred during the attacks of migraine. For these headaches he used migrainin, phenacetin and other coal-tar products, but soon gave them up, having been told that his heart action was weak. For two years he has used strychnin (gr. 1/30 t. i. d.) irregularly, and he has also tried potassium iodid, which, however, disagreed with him, and hence was discontinued. The patient had been a moderate smoker and had used beer and wine, but never immoderately. He paid little or no attention to diet and systemic exercise.

Present Illness.—The present illness began 4 years ago, the symptoms being dyspnea on exertion, cardiac palpitation and thoracic oppression. Two years ago he had a serious collapse in a patient's house, probably a syncopal attack due to myocardial weakness. He took a few doses of the fluid extract of digitalis. At the end of 36 hours he had recuperated; he then avoided overexertion and excitement, but in July, 1903, had a second attack, though less severe, and was unable to work for an entire day. The third and last seizure occurred on June 24, 1904. This case began with severe vertigo, followed by complete unconsciousness. The local symptoms (palpitation, dyspnea and oppression) have become more severe for 2 years. Since the last attack of syncope he has been troubled with flatulence, small appetite and increasing weakness. During the past year he has also had rheumatic pains in joints and muscles at intervals, but they never lasted more than 24 hours.

Physical Examination.—August 5: Impulse diffuse, wavy and exceedingly feeble, both on inspection and palpation; no thrill detectable on palpation; percussion showed the area of cardiac dullness to be greatly increased in the transverse diameter, to the left to anterior axillary line, to the right to a point ½ inch beyond the right sternal edge. On auscultation, a systolic apical murmur was heard, and the second pulmonary sound was somewhat accentuated. He began a bathing course and 2 days later the "resistance exercises" were also introduced.

August 11: The left border of the heart is now at vertical nipple line, the right at midsternum.

August 27: Impulse much stronger and apex about in normal position; left boundary line of dullness is at left vertical nipple line, while the right has moved to a point ½ inch to the left of the midsternal line; heart sounds only moderately strong, but no murmurs detectable; neither is there any appreciable arrhythmia present.

Before inaugurating treatment in this case, Prof. T. Schott gave me a remarkable demonstration of the effects of the "resistance exercises" on the dimensions of the heart. The patient was allowed to rest for forty-five minutes, when mild "resistance movements" were instituted; at the end of seven minutes the pulse had fallen from 84 to 72 a minute, while both the volume and tension had increased. After eighteen minutes of the exercises, I noted their effect on the dimensions of the heart. It will be conceded that the movements properly conducted cause a distinctly marked and decided shrinkage in the size of the heart chambers. Obviously, this reduction in size was not maintained, although persistence in the use of the exercises and baths brought about the result stated above. (Fig. 1.)

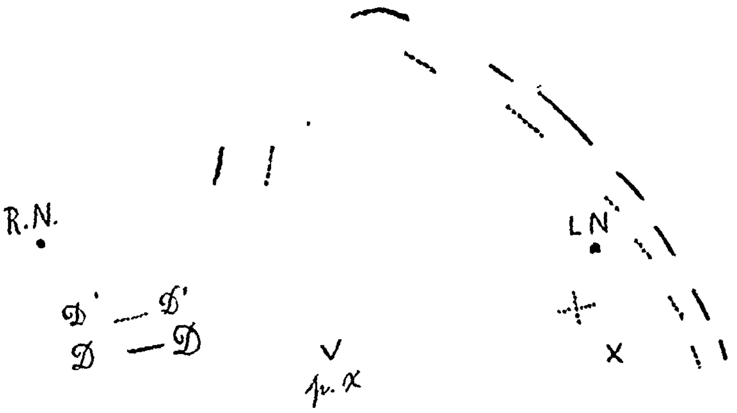

Fig. 1.—The straight lines indicate the outline of the heart: D—D, diaphragm, and X the apex beat before the exercises with resistance. The dotted line indicates the size of the heart, D'—D', the diaphragm, and the dotted *cross* the apex beat after 18-minute exercises with resistance. R. N., right nipple; L. N., left nipple.

Case 4.—A. D., aged 35, male, Russian by birth; merchant, with rather arduous duties.

History.—Childish diseases: Acute articular rheumatism at 13, complicated with endocarditis. The patient was taken to Nauheim. Professor Schott found the heart enlarged 3 cm. to the right and 2½ cm. to the left; auscultation revealed a mitral regurgitant murmur. The patient took a bathing course for 7 years in succession and was considered to be cured. Fourteen years later, he injudiciously bathed in a stream of very cold water, whereon he developed an acute articular rheumatism, from which he partially recovered as the result of treatment at home. Shortly after, or one year ago, he was again brought to Nauheim, with traces of subacute rheumatism. A single bathing course resulted in apparent cure.

Examination.—He returned this season without rheumatism, and at the end of his course of treatment I was requested to make a physical examination. The heart was found somewhat hypertrophied; the left boundary line of dullness corresponded to vertical nipple line and the right to vertical midsternal line; the impulse was vigorous and regular, and on auscultation a faint systolic murmur was detectable at the apex. The patient feels himself to be in excellent condition and indulges freely in physical exercise without fatigue. The general appearance also indicates good health. This excellent result was accomplished without the use of any medicines.

It is not claimed by the most ardent advocates of the virtues of this method that chronic valvulitis is, as a rule, curable, although a few well-authenticated cases have been recorded. On the other hand, as a means of bringing about compensation, either in simple dilatation or in that form associated with chronic valvulitis (e. g., Case 4), it possesses advantages which meet the requirements more fully and satisfactorily by far than any other known form of treatment.

It is a point of common knowledge that many patients in whom digitalis has lost its therapeutic influence come to Nauheim, and after a few baths this drug takes hold. The following is a case in point:

Case 5.—Mrs. A. H., native of Russia, aged 56; height, 5 feet 2 inches; weight, 180 pounds; father was corpulent and died suddenly at 58 years, cause unknown; all other members of the family also stout.

History.—Patient had had childish diseases, and at 36 had an attack of acute articular rheumatism following childbirth and lasting about 3 months; there was a chest complication, the precise nature of which, however, is unknown. The patient has 6 children, all in good health. Menopause occurred 5 years ago.

Present Illness.—The present illness began at that time with swelling of ankles and distress of breathing on muscular exercise. The attending physician found a heart lesion and sent the patient to Dr. Schott, who discovered a greatly dilated heart with associated cyanosis, urgent dyspnea and marked edema of the legs. The diagnosis of aortic stenosis and mitral regurgitation with secondary relative tricuspid regurgitation was made. The patient had taken digitalis, at first with marked benefit, but later without beneficial effect prior to coming to Nauheim. After a course of baths, a smaller dose than had previously been employed seemed to exercise a happy influence. The patient has been returning annually to Nauheim and each new season has found her improved. Patient is now comfortable, even after exercise, and has not required any digitalis or other cardiac stimulant during the past year.

Case 6.—General W., Englishman, aged 71, with a negative family history, although father died at 67 years, "an old man." On the whole, the family is not long-lived.

History.—Patient spent 7 years in Indian service; has never been rheumatic, but gouty at intervals, and has just recovered from an attack of lumbago. He has never paid any attention to diet, but has exercised considerably; he has been a moderate indulger in intoxicants and tobacco.

Present Illness.—He first came to Nauheim 6 years ago, and has returned each year since then; his condition at first was marked weakness, with great distress of breathing on exertion; his legs felt like lead and he could only walk a few steps when his head would reel and his sight fail. The heart action was excessively weak, with an occasional intermittence, but no murmurs were present. Each bathing course of 6 weeks brought about a decided gain from year to year, so that at present he can walk briskly for long distances. Occasionally, at night, the patient experiences a "thump," followed by a brief stop in the heart action.

Aug. 18, 1904, or at the end of the last course of treatment, I was permitted to make a physical examination. The heart was found to be of normal outline; the impulse was rather feeble, but regular, and no murmurs could be detected; the first sound was also clear with, however, some accentuation of the second aortic. The peripheral vessels are but slightly sclerosed to the touch.

The combined bath treatment and "resistant exercises" has rejuvenated this man beyond question. Without stopping to detail other similar cases, it may be stated that in no class of affections did the Schott method appear to exert more salutary effects than in moderate degrees of arteriosclerosis with embarrassment of the heart action. I observed several additional instances in which from a course of baths and exercises marked relief was afforded. The explanation is not far to seek; the lumen of the arteries, both larger and smaller, is widened, and thus the heart relieved and given an opportunity to rehabilitate itself. Whether the baths and exercises affect principally the vasomotor nervous apparatus or increase the arteriocapillary capacity in an indirect manner by favorably influencing metabolism, I can not venture to state at present writing.

Closely connected with this class of cases are those in which the atheromatous changes involve especially the coronaries and lead to the development of angina pectoris. It was my good fortune to be privileged to examine several cases of the sort and to note the results of treatment. The special effect of the Schott method was most gratifying and scarcely less than magical in many cases at least. I regret that the limits of this article will permit of my giving but a few illustrations.

CASE 7.—M. M. S., sent from San Francisco; male, aged 48; German; occupation, cigar manufacturer and wine agent; height, 5 feet 9 inches; weight, 160 pounds. Father died of chronic Bright's disease, and mother of pneumonia; all brothers and sisters, 8 in number, living and in good health.

History.—Patient had had childish diseases, after which he remained well until the age of 44, when he developed subacute articular rheumatism, lasting a couple of months; he had a recurrence the following winter, and he was cured by Kreutznoch baths. In previous years he indulged freely in beer and wine, and also smoked 10 cigars daily, on the average.

Present Illness.—Present illness began suddenly 2 years ago with numbness of arms, quickly followed by severe pain behind the sternum, which radiated to the neck and arms, especially the left; associated symptoms were cold sweats, inability to breathe, syncope and dizziness. The attacks lasted from 1 to 3 minutes and recurred from 2 to 3 times a week while engaged at work, but not so often when at rest. After two unusually severe attacks, he came to Bad Nauheim, June 14, 1904. He took 30 baths prior to July 20 (9 thermal, 10 thermal-sprudel, and 11 sprudel). From the commencement of the bathing course he experienced no pain, but felt somewhat weak and nervous for a couple of weeks, after which he felt quite strong. On July 20 he went to an "after *kur*," and remained 18 days; he returned to Nauheim feeling well, but was advised to take a brief bathing course.

August 23: He declares himself perfectly well, experiences no discomfort on walking briskly, whereas when he arrived at Nauheim walking invariably induced dyspnea and sometimes pain. Physical signs show slight dilatation in the transverse diameter, and the presence of an apical systolic murmur with accentuation of secondary pulmonary sound; there is no arrhythmia.

CASE 8.—A. A. P., Russian, aged 60; occupation, official judge; with negative family history.

History.—After child's diseases he continued well until 10 years ago, when he had influenza. He has never used either alcoholic intoxicants or tobacco; neither has he paid any special attention to diet or exercise.

Present Illness.—The present illness dates from one year ago and began with pain in the left parasternal region and radiated to arms. The primary attack was severe and lasted but a few minutes. Subsequently he experienced dyspnea on exertion, and during the following year he had three additional paroxysms of great severity. June 1, 1904, he came to Nauheim in an extremely weak condition, with hardened arteries, and the slightest attempt at exercise induced pain. He began treatment.

Aug. 23, 1904, a physical examination which I was permitted by Professor Schott to make, showed a moderate degree of right ventricle hypertrophy, while the left was practically normal; no murmurs detectable on auscultation; radials were palpable and the pulse small and irregular. He still has pain in the region of the heart on active exercise, but not true angina, and the arrhythmia, which had been present from the beginning of his illness, was now absent. The condition is greatly improved; treatment to be continued at intervals.

CASE 9.—A. K., American, aged 65, bishop; height 5 feet 8½ inches; weight, 185 pounds. Father died at 72 of stenosis of the esophagus, and mother at 55 of an aneurism; otherwise family history is negative.

History.—Escaped most childish diseases, although in delicate health all his life; at 23 he developed congestion of the lungs; for 25 years he has felt rheumatic pains in his knees and elbows; he is also troubled with nervous indigestion and attacks of troublesome diarrhea during the same period. Eight years ago he had an attack of acute rheumatism, affecting principally the left shoulder, with considerable fever, lasting one week; a heart complication developed, from which he apparently recovered.

Present Illness.—He continued well until 4 years ago, when he discovered by accident a heart lesion with dilatation. Prior to that time he had occasional vertigo, palpitation and appreciable irregularity of the heart action. Patient never smoked nor used intoxicants; had lived simply and eaten plainly, and had taken much walking exercise. For 5 years previous to being treated after the Schott method at Nauheim, he had suffered from angina pectoris of moderate intensity; the attacks especially excited from muscular exercise, and, to a lesser extent, also mental excitants. He has visited Professor Schott at Nauheim each summer for 6 years. From the first bathing course, combined with muscular exercises, the condition improved, and during the past two years he has not experienced any pain whatsoever. Patient finds that at or about the close of each winter season's arduous work he suffers from general weakness, slight dyspnea on walking, and for this reason still continues his annual visits to Nauheim.

Aug. 23, 1904, I made a physical examination and found the heart somewhat enlarged, the left boundary line of cardiac dullness corresponding with the vertical nipple line and the right falling through midsternum. Two murmurs are audible, one diastolic at the base, the other systolic at apex. The diagnosis had been aortic regurgitation with secondary relative mitral incompetency. The action of the heart is regular and pulse moderately strong. During the entire course of treatment, no medicinal measures were employed, while the heart grew steadily smaller in size and the general health better.

Granting that the baths and exercises do more good in their own attractive and restful environment than elsewhere, for example, at home, it will be conceded that such results as recorded above can not be attributed solely to this factor.

In connection with Case 3, reported above, attention was directed to the striking and immediate effects of "resistance exercises" on the size of the heart. I was also permitted, through the courtesy of Professor Schott, to note the results of the first thermal bath on the heart in a case of extreme cardiac dilatation. The notes are as follows:

CASE 10.—P. L. P., aged 31, single, German by birth; occupation, musician; height 5 feet 7 inches; weight, 119 pounds (loss of 30 pounds). The family history reveals that one sister had rheumatism and heart disease combined, and one brother died of tuberculosis.

History.—Patient has had childish diseases; at the age of 8 he had an attack of acute rheumatism, which recurred annually for 6 years. In 1893 he had pneumonia, with good recovery. He formerly indulged freely in beer, but not since the present illness began: had paid no attention to diet or exercise.

Present Illness.—The present illness began in February, 1904, as a bronchial catarrh, with dyspnea on exertion, palpitation of the heart and considerable cough; occasional night sweats and fever at intervals were present. August 23 a physical examination showed a wavy and rapid impulse, but no thrill; percussion dullness extended to midaxillary line on the left, and ½ inch beyond the right sternal edge in the opposite direction, and upward to third interspace; a murmur was heard at the apex with the systole, and at the base (slight) with the diastole; the pulse, after resting for one-half hour before the bath, was 120, small and compressible (pulse resembles that of true tachycardia at times). In the bath the patient seemed nervous, and pulse remained the same; after the bath, and after having rested for five minutes, the pulse was 116, but fuller, stronger and more regular. The physical signs after bath: Impulse seemed somewhat more forcible; the murmurs were slightly accentuated and the area of dullness decidedly lessened. This patient was sent to Nauheim by one of Berlin's foremost clinicians, but was not regarded as a suitable one by Prof. T. Schott. on arrival (Fig. 2).

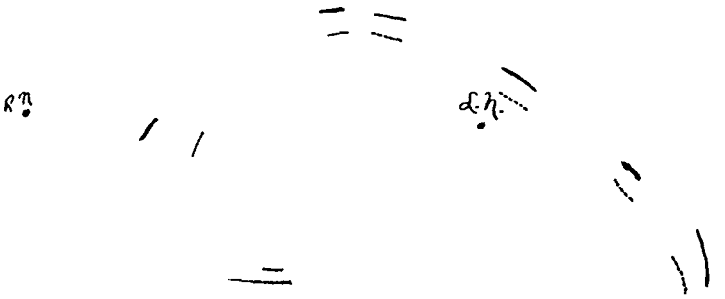

Fig. 2.—Black line, before mild thermal bath. Dotted line, after bath—8 minutes. R. N., right nipple: L. N., left nipple.

The manifest shrinkage in the size of the heart following the first bath, however, is not maintained, as holds true also in the case of the "resistance exercises"; each new bath, however, leaves the organ a little smaller than the previous one, and thus compensation is finally restored, in most cases, at least. It must be well understood that in the treatment of cases in which chronic dilatation less or more is present, the object is not alone to diminish the size of the organ, but to establish a true compensatory hypertrophy. It is to the fulfillment of this end that the Schott methods lend themselves with the most satisfactory results. It is often necessary for the patient to resume baths from year to year in order to accomplish rehabilitation of the cardiovascular forces.

There is a large class of cases, caused principally by an overstrenuous life especially involving severe mental taxation and characterized clinically by neurasthenia, evidences of malassimilation, indigestion and a moderate degree of dilatation of the heart with its usual accompaniments. This group receives striking benefits from a properly regulated bathing course. Great care is necessary in the conduct of this special mode of treatment in this group of cases, since the nervous phenomena are readily aggravated by the irritating effect of the baths on the cutaneous sensory nerves. I was permitted to observe the effects of the Schott method in a number of instances of the sort, all of which were apparently relieved. I may here cite the notes of a case in point:

Case 11.—J. T., aged 49, physician; height, 5 feet 11 inches; weight, 189 pounds. Mother suffered from mitral regurgitation, but later died of erysipelas; father also deceased at 76 years, of pneumonia; rheumatic taint on both sides of the family antecedents.

History.—The previous history furnishes the following data: Childish diseases, chorea at 12, lobar pneumonia at 17, and acute articular rheumatism (lasting 10 days) at 28 years, and a subacute attack, implicating the knees, one year ago. Social history is exceptionally good, so far as his habits are concerned; he also has regulated the diet and taken physical exercise, although not regularly.

Present Illness.—The present illness dates from his forty-third year, when he became nervous and dyspeptic; more recently he has complained of palpitation of the heart, especially on retiring, and of troublesome flatulency on partaking of starches and sweets. He has also been troubled with insomnia and irritability of disposition.

July 29, 1904, a physical examination reveals a pale, moderately well-nourished individual. Apex beat is not visible, but palpable, situated one-half inch to the left of the left vertical nipple line; this is corroborated by percussion on auscultation, the first sound is found to lack vigor and the cardiac rhythm shows great instability. No murmurs, however, are audible and the second sounds are practically normal. The patient was given thermal baths for three days; temperature of bath advised was 32.5° C.; the duration of the first bath was 8 minutes, and the second and third 10 each. A pause of 48 hours was then advised, after which three more thermal baths, to which 1 liter of "*Mutterlauge*" was added, were ordered; this reinforcement to the bath proved too stimulating, hence it was omitted after the second bath; it had caused sleeplessness and a constantly excited action of the heart; the time of these baths was 11, 12 and 12 minutes, respectively, followed by a pause of one day, then thermal-sprudel baths, varying in duration, of 8, 9 and 10 minutes, respectively, were employed. The good effects now began to manifest themselves, and the baths were prolonged to 12 minutes, but omitted every third day. After six thermal-sprudel baths had been taken, sprudel baths of a somewhat lower temperature (31° C.) were advised. On the first day the duration was but 8 minutes, second, 9, and third and fourth days, 10 minutes each; fifth day, 11 minutes, and sixth or last day, 12 minutes. A pause was taken every third day. After three days, "resistance exercises" were also employed, their duration and severity being gradually increased with the progress of the treatment. Patient was then sent to the Tyrol mountains for an "after *kur*." Up to the time he left Nauheim, he was troubled with more or less palpitation and sleeplessness and other nervous phenomena. His heart, however, had returned to its normal dimensions, so far as could be made out by physical signs. At the conclusion of the stay in the mountains, marked and rapid improvement in the condition of the nervous system ensued, and in the course of one month subsequently the patient reported that he was apparently restored to health.

Cases of exophthalmic goiter have yielded completely to the treatment, and I saw one well-marked case after a cure had been effected.

It would appear from my observation that the primary effect of this method of treatment is to provoke an aggravation of the nervous symptoms in some cases, at least, and this may readily be carried too far by the unguarded. Within certain limits, however, this stimulation exercises a salutary influence on the heart's action, the respirations and the systemic circulation of the blood, promoting the warmth of the body and regulating the tissue metabolism to an extraordinary degree. Subsequently, the excitation of the nervous system produced by the baths gradually subsides.

The "after-cure" constitutes a not unimportant element of the treatment. The patient is generally sent to an altitude ranging from 1,000 to 3,000 feet above the sea level, is rigidly isolated from professional, business and domestic cares and responsibilities, and permitted to enjoy an abundance of pure air and sunshine. With reference to altitude, it may be said that the patient's special condition must be carefully considered in reaching a judicious decision. The length of the stay is variable, although on the average about ten days to two weeks.

No presentation of the subject of the Schott methods in the treatment of chronic cardiac diseases would be complete without a brief mention of the contraindications to the treatment: 1. Cases presenting fever. 2. Advanced arteriosclerosis. 3. Far advanced myocarditis. 4. The closing stage of chronic valvulitis, with extreme dilatation of the chambers. 5. Aneurisms of the aorta or of its larger trunks, except in the incipient stage. In any case in which the blood pressure is lowered by the balneologic treatment. 7. Cases in which a tenometric figure as low as 65 or 60 mm. of mercury is found (Schott). 8. Cases in which chronic bronchitis and asthma are well marked (Baldwin).

Dr. James Tyson, in his paper cited above, has given a full and accurate description of the home-made baths, and to this paper the reader is referred for details. Tyson points out the great advisability of more conveniently available baths than those to be found at Bad Nauheim. I am in accord with this view, but I am not aware of the existence of specially trained operators to carry out the "resistance exercises"—an essential element of the method.

Moreover, the good effects of a favorable environment and of complete extrication of the patient from business and domestic cares and worriments, are, as a rule, lost when artificial Nauheim baths are attempted. If we take into consideration all these shortcomings and imperfections, there is little need to wonder at the unsatisfactory results which are only too commonly obtained. To practice the Schott method with success at home demands a separate, well-equipped and properly officered institution, and one far removed from the more densely crowded centers of population. Such an institution has yet to be produced in America.

In concluding, I desire to state that my studies and observations have fully confirmed the correctness of the principles of treatment long since established by the Brothers Schott, and unquestionably to them belongs the merit of having introduced to the medical profession a most efficient method for the treatment of those afflicted with cardiovascular diseases. Great, therefore, is the debt of gratitude which the profession owes to these gentlemen for what is most advanced and most valuable in the sum of our achievement in the treatment of this large group of affections.

DISCUSSION.

DR. JAMES TYSON said that he has limited himself to the home use of the Nauheim baths, because in this connection there is the greatest opportunity for its employment, the expense of a trip abroad and treatment at Nauheim being impossible to the majority of persons. He does not think a bath establishment is necessary and he has used the treatment in private houses in the use of the ordinary bath. A person is required to conduct the bathing as well as the exercises, although both may be done by the same individual. The baths, he believes, could be made very much simpler than the paper by William Bezly Thorne would lead one to believe. Chlorid of sodium and the chlorid of calcium were stated to be the two most important constituents. Five pounds of chlorid of sodium and five ounces of chlorid of calcium are put into the ordinary bath of from 40 to 50 gallons of water. The course consists usually of 21 baths, three of which are given in succession and then a day skipped. The proportions of sodium and calcium are increased until in the last five or six baths the water contains about ten pounds of the former and ten ounces of the latter. At home the carbonic acid element of the bath is secured by adding hydrochloric acid and bicarbonate of sodium. The cases that receive the most benefit, Dr. Tyson said, are those of cardiac weakness with dilatation, chronic dilatation brought about gradually as the loss of compensation is brought about in valvular cases, and also cases in which there has been muscular overexertion. Acute dilatation, he remarked, is best treated by rest in bed and by the use of nitroglycerin, etc. In such a case partially recovered improvement may be completed admirably by the administration of the Nauheim bath at that stage. The bath should not be given in cases of edema and general dropsy. Dr. Tyson thinks the patient a pretty good guide regarding the continuance of the bath; if he does not feel well after three or four baths, it is a mistake to continue them. Better is it to put the patient to rest. The first bath he makes five minutes in length, the second six or seven minutes, which time is increased to ten or fifteen minutes. Coincidentally with the increased duration of the bath the temperature is lowered. Eighty-two or 85, he said, is the lowest temperature at which the baths are given at Nauheim.

DR. JUDSON DALAND said that the most important features of the treatment can be subdivided as follows: The baths and movements, change of climate, régime. In the home use of the bath he attaches less value to the chlorids of sodium and of calcium than to the water and to the variations in temperature. He thinks that all physicians have gotten into the habit of using the resistance movements in combination with massage and of encouraging patients to make certain voluntary movements in cases of broken cardiac compensation. The use of the method in angina pectoris, he thinks, would be experimental. In dilatation of the heart with moderate sclerosis in persons of middle age he has found the treatment beneficial in some cases. Before instituting this treatment in such cases he determines the cardiac reaction by having the patient make a certain number of movements.

DR. S. S. COHEN referred to his demonstration before the society of the Schott treatment some eight years ago with the efficient aid of Dr. Charlotte West, and stated that Dr. West is available for the carrying out of the Schott resistance movements, as well as four other persons whom he has trained. He thinks that there is no difficulty in having the baths given at home, if the patient and physician are willing to take a little trouble in getting them started; intelligent patients can be entirely trusted to carry out the details. In preparing the bath the plan which Dr. Cohen has adopted and which has the advantages of preventing the cooling of the water and injury to the tub is to fill the tub half full of hot water, put in the brine and the bicarbonate of soda; let them remain for about twenty minutes so that they are thoroughly disseminated throughout the whole mass of water; then add sufficient water, which can be cold or lukewarm, according to the temperature to which the original quantity of water has cooled; then put in the acid sulphate cakes on the tinfoil and there will be a thorough effervescence. A valuable element in the treatment at Nauheim, Dr. Cohen believes, is the personality of Dr. Schott. His scientific spirit, his authoritative manner, thorough mastery of routine and of detail, the absolute obedience which he gets from all the attendants count for a good deal.

In the home treatment Dr. Cohen's plan is to give the baths in a course of six or eight weeks, interrupting them for eight or ten or twelve weeks and then again repeating them for two or three weeks; then again interrupting them, and again repeating. The best time to give them he considers to be at night so that the patient may have several hours' continuous rest afterward. He gives the baths every other day or every third day, giving exercise on the alternate days, if exercise is to be given. Sometimes the baths can be followed by massage, the character of which will vary with the character of the lesion and the reaction of the patient. He confirmed Dr. Anders' statement of the value of this treatment in exophthalmic goiter, but also stated that there is great danger in its employment in this condition. He would not trust patient nor attendant to give the treatment in exophthalmic goiter. In a few cases he believes it would do good if carefully applied and by the physician himself. In cases of arteriosclerosis not too

Present Illness.—The present illness began in February, 1904, as a bronchial catarrh, with dyspnea on exertion, palpitation of the heart and considerable cough; occasional night sweats and fever at intervals were present. August 23 a physical examination showed a wavy and rapid impulse, but no thrill; percussion dullness extended to midaxillary line on the left, and ½ inch beyond the right sternal edge in the opposite direction, and upward to third interspace; a murmur was heard at the apex with the systole, and at the base (slight) with the diastole; the pulse, after resting for one-half hour before the bath, was 120, small and compressible (pulse resembles that of true tachycardia at times). In the bath the patient seemed nervous, and pulse remained the same; after the bath, and after having rested for five minutes, the pulse was 116, but fuller, stronger and more regular. The physical signs after bath: Impulse seemed somewhat more forcible; the murmurs were slightly accentuated and the area of dullness decidedly lessened. This patient was sent to Nauheim by one of Berlin's foremost clinicians, but was not regarded as a suitable one by Prof. T. Schott. on arrival (Fig. 2).

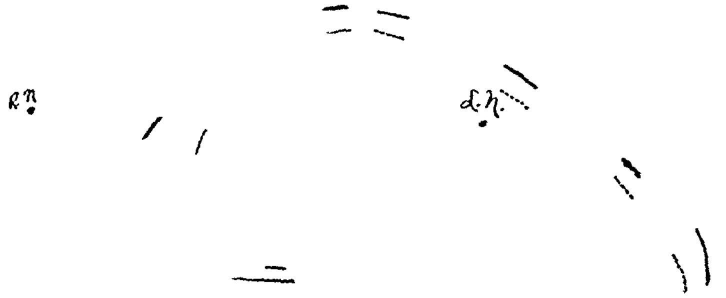

Fig. 2.—Black line, before mild thermal bath. Dotted line, after bath—8 minutes. R. N., right nipple: L. N., left nipple.

The manifest shrinkage in the size of the heart following the first bath, however, is not maintained, as holds true also in the case of the "resistance exercises"; each new bath, however, leaves the organ a little smaller than the previous one, and thus compensation is finally restored, in most cases, at least. It must be well understood that in the treatment of cases in which chronic dilatation less or more is present, the object is not alone to diminish the size of the organ, but to establish a true compensatory hypertrophy. It is to the fulfillment of this end that the Schott methods lend themselves with the most satisfactory results. It is often necessary for the patient to resume baths from year to year in order to accomplish rehabilitation of the cardiovascular forces.

There is a large class of cases, caused principally by an overstrenuous life especially involving severe mental taxation and characterized clinically by neurasthenia, evidences of malassimilation, indigestion and a moderate degree of dilatation of the heart with its usual accompaniments. This group receives striking benefits from a properly regulated bathing course. Great care is necessary in the conduct of this special mode of treatment in this group of cases, since the nervous phenomena are readily aggravated by the irritating effect of the baths on the cutaneous sensory nerves. I was permitted to observe the effects of the Schott method in a number of instances of the sort, all of which were apparently relieved. I may here cite the notes of a case in point:

Case 11.—J. T., aged 49, physician; height, 5 feet 11 inches; weight, 189 pounds. Mother suffered from mitral regurgitation, but later died of erysipelas; father also deceased at 76 years, of pneumonia; rheumatic taint on both sides of the family antecedents.

History.—The previous history furnishes the following data: Childish diseases, chorea at 12, lobar pneumonia at 17, and acute articular rheumatism (lasting 10 days) at 28 years, and a subacute attack, implicating the knees, one year ago. Social history is exceptionally good, so far as his habits are concerned; he also has regulated the diet and taken physical exercise, although not regularly.

Present Illness.—The present illness dates from his forty-third year, when he became nervous and dyspeptic; more recently he has complained of palpitation of the heart, especially on retiring, and of troublesome flatulency on partaking of starches and sweets. He has also been troubled with insomnia and irritability of disposition.

July 29, 1904, a physical examination reveals a pale, moderately well-nourished individual. Apex beat is not visible, but palpable, situated one-half inch to the left of the left vertical nipple line; this is corroborated by percussion on auscultation, the first sound is found to lack vigor and the cardiac rhythm shows great instability. No murmurs, however, are audible and the second sounds are practically normal. The patient was given thermal baths for three days; temperature of bath advised was 32.5° C.; the duration of the first bath was 8 minutes, and the second and third 10 each. A pause of 48 hours was then advised, after which three more thermal baths, to which 1 liter of "*Mutterlauge*" was added, were ordered; this reinforcement to the bath proved too stimulating, hence it was omitted after the second bath; it had caused sleeplessness and a constantly excited action of the heart; the time of these baths was 11, 12 and 12 minutes, respectively, followed by a pause of one day, then thermal-sprudel baths, varying in duration, of 8, 9 and 10 minutes, respectively, were employed. The good effects now began to manifest themselves, and the baths were prolonged to 12 minutes, but omitted every third day. After six thermal-sprudel baths had been taken, sprudel baths of a somewhat lower temperature (31° C.) were advised. On the first day the duration was but 8 minutes, second, 9, and third and fourth days, 10 minutes each; fifth day, 11 minutes, and sixth or last day, 12 minutes. A pause was taken every third day. After three days, "resistance exercises" were also employed, their duration and severity being gradually increased with the progress of the treatment. Patient was then sent to the Tyrol mountains for an "after *kur*." Up to the time he left Nauheim, he was troubled with more or less palpitation and sleeplessness and other nervous phenomena. His heart, however, had returned to its normal dimensions, so far as could be made out by physical signs. At the conclusion of the stay in the mountains, marked and rapid improvement in the condition of the nervous system ensued, and in the course of one month subsequently the patient reported that he was apparently restored to health.

Cases of exophthalmic goiter have yielded completely to the treatment, and I saw one well-marked case after a cure had been effected.

It would appear from my observation that the primary effect of this method of treatment is to provoke an aggravation of the nervous symptoms in some cases, at least, and this may readily be carried too far by the unguarded. Within certain limits, however, this stimulation exercises a salutary influence on the heart's action, the respirations and the systemic circulation of the blood, promoting the warmth of the body and regulating the tissue metabolism to an extraordinary degree. Subsequently, the excitation of the nervous system produced by the baths gradually subsides.

The "after-cure" constitutes a not unimportant element of the treatment. The patient is generally sent to an altitude ranging from 1,000 to 3,000 feet above the sea level, is rigidly isolated from professional, business and domestic cares and responsibilities, and permitted to enjoy an abundance of pure air and sunshine. With reference to altitude, it may be said that the patient's special condition must be carefully considered in reaching a judicious decision. The length of the stay is variable, although on the average about ten days to two weeks.

No presentation of the subject of the Schott methods in the treatment of chronic cardiac diseases would be complete without a brief mention of the contraindications to the treatment: 1. Cases presenting fever. 2. Advanced arteriosclerosis. 3. Far advanced myocarditis. 4. The closing stage of chronic valvulitis, with extreme dilatation of the chambers. 5. Aneurisms of the aorta or of its larger trunks, except in the incipient stage. In any case in which the blood pressure is lowered by the balneologic treatment. 7. Cases in which a tenometric figure as low as 65 or 60 mm. of mercury is found (Schott). 8. Cases in which chronic bronchitis and asthma are well marked (Baldwin).

Dr. James Tyson, in his paper cited above, has given a full and accurate description of the home-made baths, and to this paper the reader is referred for details. Tyson points out the great advisability of more conveniently available baths than those to be found at Bad Nauheim. I am in accord with this view, but I am not aware of the existence of specially trained operators to carry out the "resistance exercises"—an essential element of the method.

Moreover, the good effects of a favorable environment and of complete extrication of the patient from business and domestic cares and worriments, are, as a rule, lost when artificial Nauheim baths are attempted. If we take into consideration all these shortcomings and imperfections, there is little need to wonder at the unsatisfactory results which are only too commonly obtained. To practice the Schott method with success at home demands a separate, well-equipped and properly officered institution, and one far removed from the more densely crowded centers of population. Such an institution has yet to be produced in America.

In concluding, I desire to state that my studies and observations have fully confirmed the correctness of the principles of treatment long since established by the Brothers Schott, and unquestionably to them belongs the merit of having introduced to the medical profession a most efficient method for the treatment of those afflicted with cardiovascular diseases. Great, therefore, is the debt of gratitude which the profession owes to these gentlemen for what is most advanced and most valuable in the sum of our achievement in the treatment of this large group of affections.

DISCUSSION.

DR. JAMES TYSON said that he has limited himself to the home use of the Nauheim baths, because in this connection there is the greatest opportunity for its employment, the expense of a trip abroad and treatment at Nauheim being impossible to the majority of persons. He does not think a bath establishment is necessary and he has used the treatment in private houses in the use of the ordinary bath. A person is required to conduct the bathing as well as the exercises, although both may be done by the same individual. The baths, he believes, could be made very much simpler than the paper by William Bezly Thorne would lead one to believe. Chlorid of sodium and the chlorid of calcium were stated to be the two most important constituents. Five pounds of chlorid of sodium and five ounces of chlorid of calcium are put into the ordinary bath of from 40 to 50 gallons of water. The course consists usually of 21 baths, three of which are given in succession and then a day skipped. The proportions of sodium and calcium are increased until in the last five or six baths the water contains about ten pounds of the former and ten ounces of the latter. At home the carbonic acid element of the bath is secured by adding hydrochloric acid and bicarbonate of sodium. The cases that receive the most benefit, Dr. Tyson said, are those of cardiac weakness with dilatation, chronic dilatation brought about gradually as the loss of compensation is brought about in valvular cases, and also cases in which there has been muscular overexertion. Acute dilatation, he remarked, is best treated by rest in bed and by the use of nitroglycerin, etc. In such a case partially recovered improvement may be completed admirably by the administration of the Nauheim bath at that stage. The bath should not be given in cases of edema and general dropsy. Dr. Tyson thinks the patient a pretty good guide regarding the continuance of the bath; if he does not feel well after three or four baths, it is a mistake to continue them. Better is it to put the patient to rest. The first bath he makes five minutes in length, the second six or seven minutes, which time is increased to ten or fifteen minutes. Coincidentally with the increased duration of the bath the temperature is lowered. Eighty-two or 85, he said, is the lowest temperature at which the baths are given at Nauheim.

DR. JUDSON DALAND said that the most important features of the treatment can be subdivided as follows: The baths and movements, change of climate, régime. In the home use of the bath he attaches less value to the chlorids of sodium and of calcium than to the water and to the variations in temperature. He thinks that all physicians have gotten into the habit of using the resistance movements in combination with massage and of encouraging patients to make certain voluntary movements in cases of broken cardiac compensation. The use of the method in angina pectoris, he thinks, would be experimental. In dilatation of the heart with moderate sclerosis in persons of middle age he has found the treatment beneficial in some cases. Before instituting this treatment in such cases he determines the cardiac reaction by having the patient make a certain number of movements.

DR. S. S. COHEN referred to his demonstration before the society of the Schott treatment some eight years ago with the efficient aid of Dr. Charlotte West, and stated that Dr. West is available for the carrying out of the Schott resistance movements, as well as four other persons whom he has trained. He thinks that there is no difficulty in having the baths given at home, if the patient and physician are willing to take a little trouble in getting them started; intelligent patients can be entirely trusted to carry out the details. In preparing the bath the plan which Dr. Cohen has adopted and which has the advantages of preventing the cooling of the water and injury to the tub is to fill the tub half full of hot water, put in the brine and the bicarbonate of soda; let them remain for about twenty minutes so that they are thoroughly disseminated throughout the whole mass of water; then add sufficient water, which can be cold or lukewarm, according to the temperature to which the original quantity of water has cooled; then put in the acid sulphate cakes on the tinfoil and there will be a thorough effervescence. A valuable element in the treatment at Nauheim, Dr. Cohen believes, is the personality of Dr. Schott. His scientific spirit, his authoritative manner, thorough mastery of routine and of detail, the absolute obedience which he gets from all the attendants count for a good deal.

In the home treatment Dr. Cohen's plan is to give the baths in a course of six or eight weeks, interrupting them for eight or ten or twelve weeks and then again repeating them for two or three weeks; then again interrupting them, and again repeating. The best time to give them he considers to be at night so that the patient may have several hours' continuous rest afterward. He gives the baths every other day or every third day, giving exercise on the alternate days, if exercise is to be given. Sometimes the baths can be followed by massage, the character of which will vary with the character of the lesion and the reaction of the patient. He confirmed Dr. Anders' statement of the value of this treatment in exophthalmic goiter, but also stated that there is great danger in its employment in this condition. He would not trust patient nor attendant to give the treatment in exophthalmic goiter. In a few cases he believes it would do good if carefully applied and by the physician himself. In cases of arteriosclerosis not too far advanced he has seen good results; also in angina pectoris, in mitral stenosis and in mitral regurgitation. He differed from Dr. Daland concerning the resemblance between the effect of active exercise on the part of the patient and the gentle resistance movement of the Schott system. In the Schott system there is no muscular exercise on the part of the patient at all. The moment exercise is made the patient defeats the object of the treatment. The method is, he said, *"gentle resistance."* The benefit obtained is in the starting up of the peripheral muscular pump on the vessels so that the action of the natural *rhythmical contraction* of the muscles on the vessels continued to assist the work of the heart. The carbondioxid gives to the "skin heart" a much more active stimulation than could be secured from massage or electricity, though the principle is just the same, the diversion of the blood to the surface and the stimulation of the vasomotor reaction.

Dr. P. S. Donnellan said that he believes it is the combination of the baths, the resistance exercises, the environment and the care in diet which contribute to the success of the Nauheim treatment. A good feature, he pointed out, is that the bathtub is sunken into the ground. He considers the resistance exercises a valuable addition to the treatment in that they supply a distinct element of cure in those cases of cardiac dilatation, arteriosclerosis and some valvular conditions. He thinks that great care should be exercised in the selection of cases sent to Nauheim. He referred to the importance of the after-cure, which consisted in the patient being sent to the ck Forest or to some portions of Switzerland to complete cure after a period of six or eight weeks' treatment at heim.

Dr. William S. Wadsworth referred to the physiologic principles underlying all treatment. In regard to the effect of the various ingredients of the bath on the stimulation of the skin and the effect on the sensory nerves, there is, he said, a very great additional effect not mentioned, the effect on the skin itself. For example, on putting a piece of skin, alive or dead, into water there is obtained a certain amount of maceration and an entire change in the feeling of the skin. If the finger is put into the water for half an hour the sensations are entirely different from those encountered from the air. All, he said, know the difference between the sea bath and the ordinary bath. Another factor in the bath, he pointed out, is the suspension of the body in a material which is of a certain specific gravity. Putting the body on a water bed, he considered, is also a very important factor. The changes of the specific gravity will bear the closest clinical study and should give interesting results. In the resistance movements Dr. Wadsworth stated there is a series of valuable factors developed of a purely mechanical sort. On the chemical side there is another group; a chemical change taking place in the muscle itself. Certain substances are taken up, causing change of tone of the whole system. Fatigue stuffs are thrown out which have a distinct effect on every organ that comes in contact with the blood.

Dr. J. Madison Taylor emphasized the importance of the physician, himself knowing enough about the question of exercise to direct a competent person to do the work. He thinks much can be gained if men will take the trouble to study their cases thoroughly, and watch them through from start to finish.

Dr. J. M. Anders said that he is not convinced that the home treatment can be carried forward with much success. To have a suitable establishment in this country would require a specialist in heart disease to make the treatment a special study, and this one should watch the patient daily, noting the effect of every bath and every application of the resistance movements.

Formaldehyd for Disinfecting.—An improved method of disinfecting is the subject of a recent English patent, according to the *Pharmaceutical Era*. One part of paraformaldehyd and six parts of carbon, both in finely powdered condition, are mixed with sufficient gum tragacanth or other suitable gum to form a stiff paste, which is pressed into blocks and dried. When required, the blocks are ignited, formaldehyd vapor being thereby gradually and uniformly disseminated.

PARAURETHRITIS.

AN ANATOMIC REVIEW, WITH A REPORT OF TWO CASES.

J. W. CHURCHMAN, M.D.
BALTIMORE.

The recent occurrence within ten days of two rather unfamiliar forms of gonorrheal infection seemed to offer material of enough clinical interest to be worth recording and of enough anatomic interest to warrant detailed study of the structural features illustrated; and at the suggestion of Dr. Young,[1] in whose practice the cases occurred, the following report has been prepared:

The urethra may be roughly described as a tubular structure, with dependent glandular adjuncts; for throughout its whole extent, from meatus to internal sphincter, and even beyond in the trigone, glands or crypts are to be found occupying a "para-position" in relation to it. All of these are of clinical interest as haunts of infection; some, like the prostate and vesicles, have, beside, a very definite pathologic and physiologic interest of their own; but many (most of them, though small, by no means insignificant) bear so intimate a relation to the urethra that we can only speak of them as paraurethral and of their infection as paraurethritis. Strangely enough, the well-known proper names associated with many of these structures are so associated with little or no justice. Tyson's glands do not exist; Skene's glands were described and their gonorrheal infection noted by Astruc 125 years before the American publication, and again by Guérin in 1864; Littré was probably looking at something quite different from the glands which have since borne his name when he noted structures in the membranous urethra which were, as now seems likely, not glandular at all; and Cowper was antedated just eighteen years by Méry in describing the glands usually known as his.

For their discoverer, in 1680, there was no doubt as to the glandular nature of the depressions he saw on corona and cervix, and from their supposed function (they were first observed in the orang-outang) Tyson called them odoriferous glands. Morgagni subsequently denied their existence as anything more than depressions. So did Haller, Finger and others; and Sprunk, in a Königsberg thesis (1897), reported that an examination of 300 adults had failed to reveal Tyson's glands in a single case. Kölliker, taking a safe middle position, regarded them as inconstant, and only sebaceous glands at best. It seems quite probable, as Delbet[2] has shown from a study of the published cases, that what Tyson and others took to be true glands were only the papillæ and interpapillary spaces of Littré, and that there are no true glandular structures on corona or cervix. Behind the corona and on the mucous layer of the prepuce there are, of course, sebaceous glands, atrophied and rudimentary, and the products of these unite with some desquamated epithelium to form smegma.

The features of the urethral mucosa proper begin with the valve of Guérin, an epithelial transverse fold lying in front of the fossa navicularis, which it closes off somewhat as the aortic valve does the aorta. It is sometimes described as analogous to the lacunæ of Morgagni (so Janet[3]); but both its histology (its epithelium is squamous in type) and its embryology show that it really deserves separate consideration. For the genito-urinarian it is chiefly of interest as offering resistance to the introduction of instruments; and it provides the stereotyped exception for that stereotyped rule of the textbooks about hugging the superior urethal wall in passing sounds. Just back of this peculiar valvular fold begins the familiar series of glands and lacunæ usually associated with the names of Morgagni and Littré. Of these glands it may in general be said that they are more numerous on the upper (anterior) wall than on the lower (posterior); that they are present throughout the urethra, reaching even into the bladder as the aberrant glands of Littré, and that they appear about the third month of fetal life, though their development probably continues after birth (Rubin and Cadiat). Around the prostatic portion they lie in linear series; in the membranous they are scattered without order, though Motz and Bartrina[4] have recently called attention to the clinical importance of certain definite groups; and in the spongy portion they are abundant on the upper and numerous on the lateral surfaces. Their importance as harborers of gonococci needs, of course, no mention. The crypts of Morgagni—blind depressions, having the same structure as the urethra, and not glandular at all—are found from the valve of Guérin to the membranous urethra, where they usually disappear. They are arranged in linear series and were divided by Morgagni into foramina and foraminula, to which Sappey made the somewhat superfluous addition of a middle class. In the median line and on the dorsal surface they are largest, reaching their maximum in the well-known lacuna magna of the fossa navicularis. One 27 mm. deep was reported by Cruveilhier, but usually they do not run more than 6 or 7 mm.

---

[1] I am also indebted to Dr. Young for suggestions as to the best use to make of the material he was kind enough to put at my disposal.

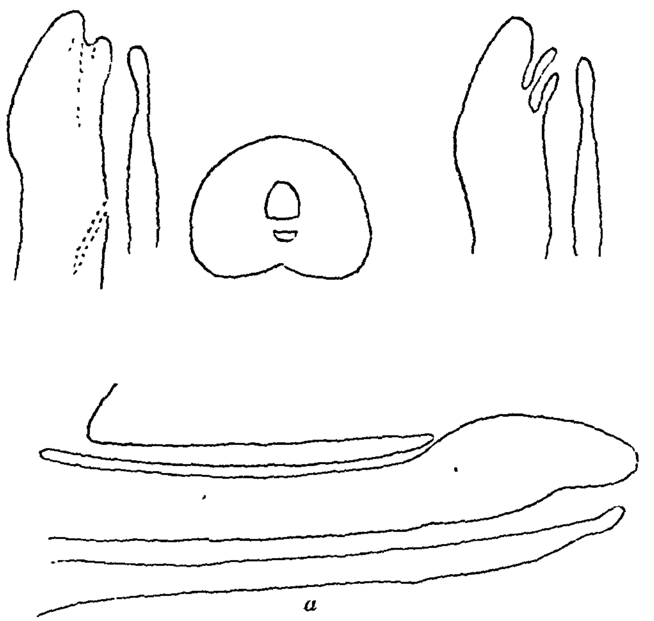

Fig. 1.—Diagram of paraurethral structures above the urethra. a. True dorsal fistula. (Modified from Janet.)

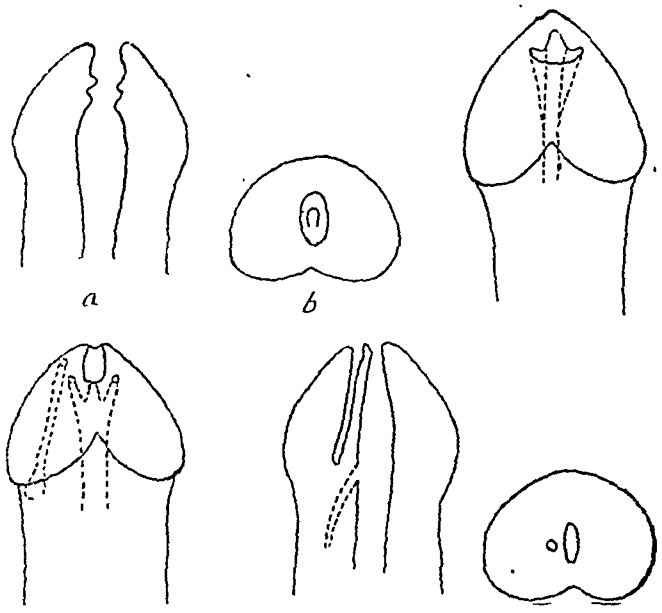

Fig. 2.—Diagram of paraurethral structures lateral to the urethra. a. Diaphragm formation; seen at b. reaching only partly around the urethral circumference. (Modified from Janet.)

In the female the urethral glands have less clinical importance, in proportion as urethritis is a less troublesome disease. In the clitoris, the morphologic analogue of the glans, no true glands exist, though there is usually a mucous crypt on the posterior inferior face, where in one case Wertheimer found the opening of a true clitoridean gland. In the urethra itself true acinous glands, though less numerous than in the male, exist throughout its extent. Of much greater interest and importance, however, are the well-known paraurethral structures to which Skene's name, by a sort of common consent, has become inseparably attached. Anatomically they are a puzzle. For a long time supposed to be the remains of Gärtner's canal, they were later explained as analogues of the urethral lacunæ; but their early appearance (they are first seen in the 65 mm. fetus), their constancy in the human female, and their general developmental history, make it probable that they are really homologues of the *prostatic* glandules—a probability pointed out by Astruc as early as 1755. The position of their orifices, the general course of their canals and their relation to urethral infections suggest quite strongly their clinical analogy to the paraurethral ducts seen in the male, whatever be their exact anatomic nature.

All these features of the male and female urethra occur with enough constancy to be considered normal. In a certain number of cases, however, additional depressions and ducts are found, whose infrequent occurrence gives them anatomic and clinical interest. They may take various forms,[3] from a mere depression on the lip of the meatus to the system of small canals, giving to the glans of hypospadias a veritable moth-eaten character. In any case, they are admirably fitted to store away the elusive organisms—better fitted, of course, as their complication or the deepness of their site increases. Most frequently they occur as small openings on the lips of the meatus, which may prove to be mere depressions (Fig. 1), the mouths of culs-de-sac, or the orifices of true, and, in some cases, long canals, running in general parallel with the urethra (Fig. 2). Varied, too, are their terminations; now they lie beside the meatus as pin-point orifices or suggesting a double meatus; again they are found to open into the fossa navicularis, like a complete fistula; occasionally they burrow through one urethral wall to form a true sinus (Fig. 3a); sometimes (the subphrenal pouches) they run along in the prepuce, where they may be felt as cords, to open into the urethra, or exteriorly, or both (Fig. 3a). In other cases a transverse depression occurs in the lateral walls of the fossa navicularis and forms a diaphragm running, in certain of the patients, only partly around, and suggesting, by the combination of a vertical with a transverse meatus, the beginning of hypospadias (Fig. 2b). A true dorsal fistula may also occur, beginning just behind the glans and running back to the pubic symphysis (Fig. 1a). It is easy to see how complicated a picture combinations of these conditions may give, and this is what we actually get in hypospadias. In this deformity small median depressions on the floor of the false meatus, or of what is really the opened fossa navicularis, are very frequently seen (Figs. 3c and 4); but all sorts of lateral and median canaliculi have also been observed, all of which, except the large, pouch-like urethral auxiliaries seen in Figure 3b, were observed in a patient of Guyon's (Fig. 3c), the richness of whose penile anatomy was somewhat counterbalanced by the co-existence of monorchism. Of the unusual paraurethal gland-like structures it may then, in brief, be said:

[4] Motz and Bartrina: Contribution à l'Etude des Abscès Périnéaux et des Phlegmons diffus d'Origine urétrale, Annales des Maladies des Organes Génito-Urinaires, No. 21, Nov. 1, 1903.

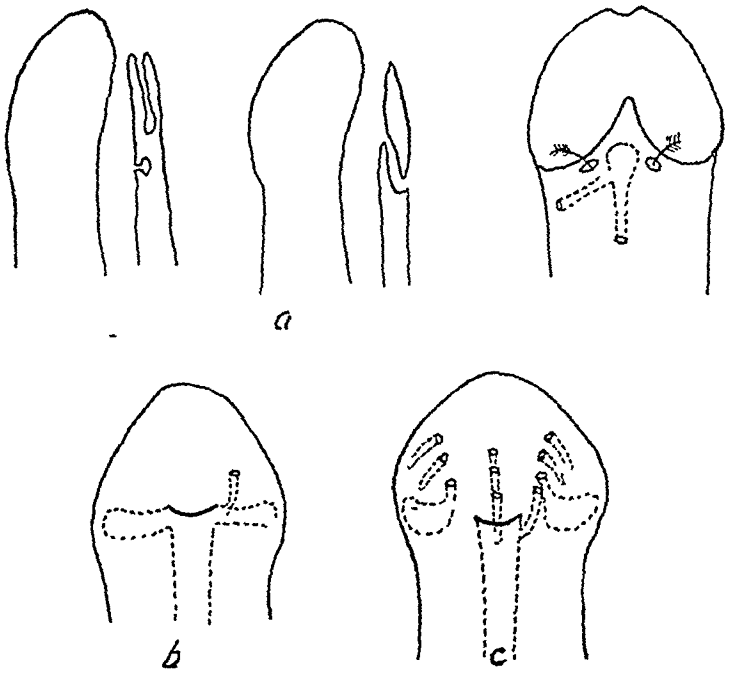

Fig. 3.—a. Diagram of paraurethral structures below the urethra. b. Lateral urethral pouches. c. Guyon's case. (Modified from Janet.)

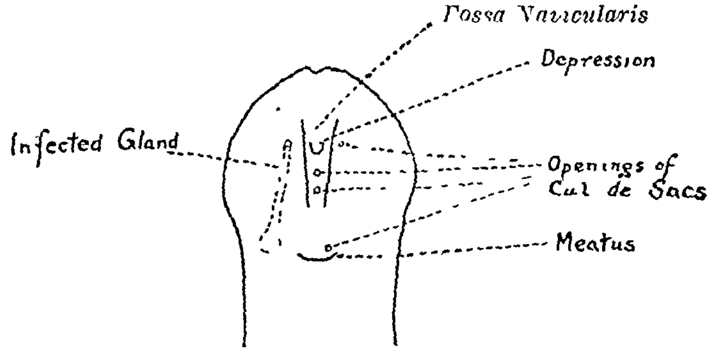

Fig. 4.—Diagram showing conditions in Case 2. (D. C.)

1. They are more frequently seen with hypospadias than in the normal penis.
2. They may occur above, below or lateral to the urethra.
3. They are oftenest seen, when hypospadias is not present, on the lips of the meatus.
4. They vary in extent from slight depressions to long ducts.
5. They may be independent of the urethra or directly connected with its lumen.
6. They secrete a clear serous fluid.
7. They may take the form of a true fistula running either more or less parallel with the urethra or burrowing through the body of the penis to connect with its lumen.
8. The most frequent form, in hypospadias, consists of median depressions in the wall of the fossa navicularis.
9. They may be responsible for persistent infection by offering a safe haunt for organisms.

In the deeper portions of the urethra we find, of course, paraurethral structures analogous to those in front; but these, by reason of their familiarity and their right to a consideration as distinct organs rather than urethral adjuncts, do not concern us here. It may be of interest, however, to note, in connection with the question of infection of paraurethral structures, the valuable article recently published by Motz and Bartrina.[4] These writers, from a study of a large number of pathologic specimens, have come to the somewhat novel conclusion that the conventional ideas about perineal abscess following stricture are all wrong; that Hunter was on the right track when he spoke of these conditions as primarily urethral or periurethral suppurations; that they actually start in suppuration of the "urogenital glandular thoroughfare," composed of prostate, vesicles, Littré's glands, Cowper's glands, and the aberrant Cowper's or intrabulbar glands; that often, if not usually, the urethra is intact, and that "infiltration of urine" is a misnomer for what is really a diffuse bacterial phlegmon (Albarran's "acute septic edema of urinary origin"), the urine being not causative at all, but quite secondary.

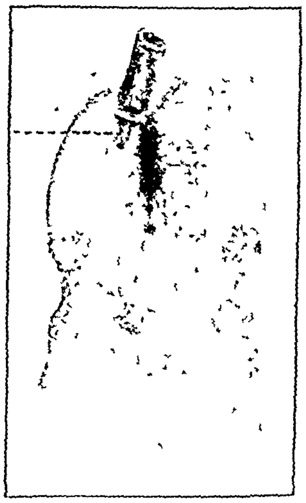

Figure 6.

Fig. 5.—Showing a drop of pus exuding from infected gland in Case 2. (Drawing from photograph.)

Fig. 6.—Showing extent and direction of infected gland in Case 2. a. Hypodermic needle. (Drawing from photograph.)

Case 1.—(S. W.) This was a case of paraurethral infection appearing during the course of a urethritis and occurring in an otherwise normal penis. The patient was first seen on Nov. 26, 1902. The history was of exposure five days previously. There had been urethral burning for three days, but the discharge had not been seen until the day before admission. The left inguinal glands were palpable. There was pus in the first glass; the second and third were clear; the patient denied all previous genitourinary trouble. Gonococci in great numbers were found in the discharge and the case was, of course, one of ordinary acute anterior gonorrhea. The usual treatment with daily irrigations was instituted, santal being given internally and the patient advised to drink copiously of water. For three weeks the course was uneventful, the urine showing no posterior involvement and the discharge gradually diminishing in amount and becoming more chronic in character.

On Sunday, December 26, patient first noticed a small papule on the glans penis near the urethral orifice. On examination I found a pin-point opening on the lips just to the left of the meatus and about opposite its middle point, surrounded by a reddened area with no accompanying induration. On squeezing, a small drop of pus exuded, rich in gonococci. A fine probe could be inserted for a distance of about 3 cm., and ran back and somewhat to the left. No other gland could be found. The urine, which on the patient's last visit had been suspicious of posterior involvement, now pointed to it plainly so that posterior irrigations of 1 to 10,000 silver nitrate were started—treatment of the urethritis from this time on taking the usual course. The infected paraurethral gland was touched with pure carbolic acid on a fine probe, a small piece of cotton was inserted between foreskin and glans and the latter cleaned with peroxid. For the next three days the paraurethral gland continued to discharge despite daily touchings with pure carbolic acid. On January 13 a very little seropurulent discharge could be squeezed from the gland, made up of disintegrated pus cells. One cell was seen containing gonococci. The next day an injection of 2 per cent. protargol was given with a blunt hypodermic needle, and on the 19th no pus could be obtained and no induration felt. On the 22d, however, a fairly large number of gonococci were found in the pus squeezed from the gland and an injection of peroxid was given. The patient was next seen on February 11, when the paraurethral infection had entirely subsided and no discharge could be squeezed from the gland. The subsequent history was the conventional story of chronic urethritis.

CASE 2.—(D. C.) This was one of paraurethritis appearing as the primary gonorrheal lesion in a patient with hypospadias. This penile deformity was an inheritance which had come through the mother's family, three maternal uncles and one maternal great uncle having had hypospadias exactly similar to the patient's. Two brothers, both dead in infancy, had no such deformity. The accompanying very small urethral orifice had, during childhood, given the patient no trouble except the inconvenience of a small urine stream. There was no history of nocturnal enuresis. At 9 years of age the patient was circumcised and the urethral orifice enlarged. Since his fourteenth year he had a good deal of urethral irritability, which began after a small dose of turpentine followed shortly afterward by dreadful strangury without hematuria. Since this time, however, when the urine is dark in color and "concentrated," urination has been accompanied by mild burning. A second attack of strangury without hematuria occurred last year subsequent to the taking of a large number of oranges. There was no history of previous genitourinary trouble. The patient was first seen January 8, giving a history of exposure on December 29 and 31, to the second of which he had reason for tracing his infection. There had been no previous exposure since October 15. Absolutely nothing was noticed until the morning of January 7, when there was some slight itching on the glans. On the night of the 7th a slightly inflamed point on the right lip of the false meatus was noticed, without any suspicion of urethral symptoms. The patient, who was a medical man, thought immediately of lues and spent a miserable night with the books of his student days. He was seen next morning in a highly nervous state, thoroughly convinced that two years of mercury and iodids lay before him. On examination the testicles were found normal, the globus major on both sides palpable, but not tender; veins of the cord enlarged. No rash, glands nor constitutional symptoms. The penis was deformed, as shown in Figure 4. On the right lip of the open fossa navicularis, about one inch from the true meatus, was a small reddened papule with no surrounding induration. No opening was to be seen, but on squeezing the papule a small drop of pus exuded (Fig. 5). A smear showed intracellular diplococci somewhat larger than gonococci and not uniformly stained. Nor was the Gram test decisive, some of the organisms decolorizing and others retaining the stain; but smears made next day on hydrocele agar gave a pure culture of gonococci with a typical Gram reaction. The urethral orifice was somewhat reddened, but there was no sign of discharge nor had there been any burning or other sensation. In the first glass were a few flakes of pus which did not contain gonococci; second and third glasses absolutely clear. The glandular orifice was cauterized with pure carbolic acid, the glans and then the anterior urethra well washed with potassium permanganate. The patient was told to keep the glans clean with peroxid. That afternoon the gland was again cauterized, the anterior urethra washed with a mild bichlorid solution, after carefully cleaning off all infection from the glans, and an effort made toward prophylaxis of the anterior urethra, possibly not yet infected, by an instillation of a 2 per cent. protargol. Lafayette mixture and large quantities of water were ordered internally. Next day there were still shreds in the first glass and carbolic cautery for the gland with 2 per cent. protargol in the urethra was again used. This was repeated on January 10, and on January 11 protargol, 2 per cent., was injected into the infected gland with a blunt hypodermic needle (Fig. 6), the glans being afterward wrapped in cotton soaked with protargol which, owing to the deformity, could fortunately be made to cover the infected orifice without blocking the urethra. January 12 the gland was still discharging; a smear made just at the meatus showed some gonococci, but as there was no discharge beyond a small amount of mucus, and as there had been absolutely no symptoms, it was felt that these might well be accidental from the infected gland and not from an infected urethra. A few flakes of degenerate pus continued in the first glass, but no gonococci could be found in it. On January 13 there was slight enlargement and tenderness of the glands of both groins and the patient reported having had priapism, without pain or chordee, during the previous night. Next day there was a slight amount of pus at the meatus which contained gonococci. The usual treatment of the gland was continued and regular tridaily permanganate irrigations of the anterior urethra were started (1 to 2,000, increasing to 1 to 800). On January 16 a lymphangitis running along the left side of the penis was noted. The gland was irrigated with 1 to 1,000 bichlorid and injected with 2 per cent. protargol. On January 17 pus could be squeezed from the gland in quantity and peroxid was injected with a blunt hypodermic. January 19 there was marked improvement. The urethral conditions remained the same and no gonococci could yet be found in the flakes of pus which continued in the first glass. On January 25 silver nitrate, 1 to 5,000, was substituted for permanganate in the urethral irrigations. No gonococci could be found in a smear from the urethra nor in the pus of the first glass. On January 26 the patient complained of some pain in the right hip joint and next day he was confined to bed with grip. Gonococci gradually decreased in number under treatment and on February 9 they could not be found in the gland which, four days later, was absolutely healed. Continued search for organisms in the urethra and in the few shreds which continued in the first glass failed to reveal them, but an irrigation test showed that some of the shreds had a posterior origin and posterior irrigations were started on February 11. Slight strangury followed their use, and on February 17 patient was taken with rectal pain, a severe chill, vomiting and temperature of 100 degrees. This condition lasted all night, but patient was well again next day. On February 28 examination of anterior urethra on a bougie was made and a few small indurations found. The massage caused some burning and on the night of March 2 patient had a chill with vomiting and fever. A few shreds still persisted in the first glass and a few indurations were palpable on a bougie, but there were no symptoms, and the prostatic examination showed only a few leucocytes in the secretion.

REMARKS.

This case was of interest by reason of the co-existing hypospadias,[5] the doubtful diagnosis in its early stage, when it might easily have been taken for a beginning chancre, a small chancroid or even an infected herpetic blister; the subsidiary character of the urethritis (due largely, no doubt, to the accident of co-existing hypospadias), the presence of unusual urethral irritability, making treatment difficult, and the long persistence of gonococci in the infected duct in spite of vigorous treatment. Indeed, having once seen a paraurethral infection, one wonders not that gonorrhea is so seldom cured, but that it is ever cured; and to have observed a duct, thoroughly irrigated with 1-1,000 bichlorid and then cleaned with hydrogen peroxid, the next day discharging gonococci in numbers, makes it easy to understand why gonococcicides have been more numerous than uric acid solvents, and equally effective. The observation of such a case impresses one with the importance of the mechanical effect of irrigations in urethritis, and the relatively small importance of the specific "anti" effect of the material used. The intraurethral glands are, of course, not so deep as the paraurethral glands, but the conditions there are similar to, if not so extreme as, the rarer affections; and in them, as in the paraurethral cases, the gumming of the glandular mouth, with the formation of a sealed tube containing a pure culture of gonococci in a congenial medium, ought, it seems to me, to be combated by irrigations, the frequency of which is of more importance than their composition. In my first case the gland was quite shallow, urethritis was already present, and the treatment was, therefore, quite unimportant. In the second case, conservative measures were persisted in, consisting of irrigations, strong antisepsis and cauterization, for it seemed unwise to cause any bleeding in the presence of a blood-infecting organism; and, moreover, to have converted this cul-de-sac into a sinus open at both ends, while it would, of course, have given better drainage, would, at the same time, have brought the source of infection nearer the meatus and so have abused the very protection against urethritis which Nature had provided in the hypospadias. Operative measures have, however, been advised, and Janet[3] has devised special instruments for the purpose, the object being either to convert the blind internal fistula into a complete fistula by incising it toward the urethra, or to open its blind end and so provide for through-and-through drainage. The method of incision was used with good results by Genouville[6] in a case of gonorrhea involving two glands, lateral to the frenum, without a co-existing urethritis; and in a case of recurrent gonorrheal urethritis traced to a latent infection of paraurethral gland in a patient with hypospadias (the canals opening both into the urethra and externally) Reymond effected a cure by instillations of strong permanganate. In Swinburne's[7] four cases operative treatment was avoided, application to the infected gland being relied on, together with whatever urethral treatment was indicated. One of these cases resembled my second case in several important particulars, for, though there were never any symptoms of urethritis (the infection was lodged in paraurethral meatal glands) and no cloudiness in the urine, gonococci, which, as a rule, could not be found in the urethra, occasionally appeared there, just as I was able to find them now and then without having caused as much burning as the patient often experienced in his uninfected irritable urethra and without appearing there with any consistency.

---

[5] I have since seen a patient with chronic urethritis and hypospadias who showed paraurethral ducts on the right lip of the fossa navicularis and just to the left of the true meatus (similar to the condition in Case 2). Both are now perfectly normal, but there is definite history of their involvement during the acute attack four years ago.

It would be interesting to compare the frequency of paraurethritis with the proportion of males having the anatomic abnormality necessary for its development. Theoretically, it is hard to conceive that such glands, when present, would ever escape infection, lying directly exposed, as they do, not only to the original source of infection, but also to the discharges of a urethritis. The strange freaks of contagion, however, are not to be theoretically prophesied with any exactness, for in my second case the urethra, to which careful prophylactic attention was paid, showed signs of at least temporary infection and continually provided the urine with shreds, while the small gland on the opposite meatal lip, though unavoidably exposed and practically untreated, escaped infection entirely. The number of gonorrheal cases with infected paraurethral glands ought to be the same as the number of gonorrheal cases with paraurethral glands to infect; and the relative rarity of paraurethritis means probably that it is frequently overlooked, and that paraurethral glands are a rather rare anatomic feature. In women in whom "gonorrheal urethritis is an almost constant manifestation of fresh infection" (Bumm[8]), Skene's ducts, occupying a site of somewhat similar exposure, are, of course, very frequently infected, causing the well-known reddened, pouting projections at the meatus; so that, whatever may be the exact anatomic analogy between the glandular structures of the male and the female lying near the urethral orifice, the frequency and importance of infections in the exposed paraurethral glands of the female lend clinical support to the otherwise theoretic presumption that the importance and frequency of their involvement in the male may have been overlooked.

SUMMARY.

The cases here reported show that:

1. Gonorrheal infection of paraurethral ducts occurs in the male, and that it may manifest itself either during the course of an ordinary urethritis or before urethral symptoms have appeared.
2. Paraurethritis may, in its very early stages, simulate inflammatory lesions of the surface of the glans, notably beginning chancre, chancroid, or herpes.
3. Paraurethral infection, once it has become established, can be destroyed only with great difficulty, the organisms reappearing in abundance even after cauterization of the duct.
4. The infection can be overcome without surgical intervention, and the continual existence of a neighboring focus of infection does not necessarily mean a bad urethral invasion if careful prophylactic measures are taken.

Clinical Report.

PAPILLOMA OF THE ASCENDING COLON UNDERGOING MALIGNANCY.

ILEO-COLOSTOMY (LATERAL IMPLANTATION); ILEOCECO-COLECTOMY; RECOVERY.*

LEWIS WHITAKER ALLEN, M.D.
Attending Surgeon to St. Luke's Hospital.
SAN FRANCISCO.

Papillomata occur in the colon with sufficient rarity as compared to their appearance elsewhere, e. g., in the mucous membrane of the nose, ear, larynx and genitourinary tract, to justify the report of this case.

* Reported before the San Francisco Academy of Medicine, September, 1904.

Patient.—Mr. S. B. DeS., an Englishman, aged 36; good family history.

History.—He was always strong and well until the middle of May, 1903. He then complained of a burning sensation in the stomach and colon, of occasional attacks of vomiting, and of loss of strength and flesh. Within a week he noticed blood in the stools. He gradually grew worse, vomited nearly all food, and had small, black, thin stools daily. He lost 42 pounds in 10 weeks.

Examination.—Physical examination showed the heart and lungs to be negative. The abdomen was tympanitic, except on the right side, where palpation revealed a large, hard mass in the ileocecal region extending up to the free border of the ribs. This mass was not sensitive and could not be moved freely.

Treatment.—He was given large enemata of olive oil and olive oil was given by mouth, beside stimulation. He retained the olive oil but vomited all nourishment. He had a movement of small, thin, black stools, containing hard pieces of fecal matter.

Course of the Disease.—This condition of the stools, showing disintegrated blood and hard, marble-like feces, continued until October 1, the patient several times suffering from collapse, at which times his pulse became imperceptible. By October 1 he had lost greatly in flesh and strength, and was profoundly anemic. His emaciation was extreme. There was, however, now no blood in the stools. There was no vomiting and less flatulence. The mass had diminished to the size of an orange, situated in the right iliac region, and had become somewhat more movable. The blood in the stools disappeared with the hard scybala. Through the succeeding months his gain in strength was slow but continuous. April 13 I first saw the patient in consultation with Dr. Harris. I found a fairly well nourished, though anemic patient. His abdomen was normal in appearance, but a mass the size of a small orange could be made out through the newly acquired adipose tissue, in the right iliac fossa. It was freely movable, not tender, and at this time was giving the patient no discomfort. The abdomen was tympanitic over it. It was about the size of a chronically inflamed appendix with a moderate amount of adhesions about it.

Diagnosis.—The question of diagnosis was of some interest. As soon as the colon had been cleared of all scybala the hemorrhage stopped and the patient began to improve. Carcinoma and other malignant growths were now considered improbable. The fact that no bleeding had occurred for so many months forced one to consider other conditions than a papilloma. If the extreme condition to which the patient had been brought was due to the hemorrhages as a result of ulcerations produced by the scybalæ, then the tumor, as found at this time, might be a gumma, hypertrophied gland, or a mass of adherent intestines resulting from the previous ulcerations with peritonitis, or a chronically inflamed appendix with adhesions. There were neither symptoms nor history of syphilis. The growth was too large and too movable to be an enlarged gland. Besides, such a gland would have subsided during these months of convalescence. The mass seemed to have too much solidity to be adherent intestine only. Barring malignant growths, it felt more like a chronically inflamed appendix, surrounded by a mass of adhesions, than anything else. The persistency of the irritability of his stomach seemed to bear this out. Lack of an increase of temperature would mean nothing, as this often is lacking in chronic appendicitis. It was, however, a case for exploratory incision as soon as the patient was in condition. His anemia contraindicated any extensive operation at that time unless necessary, and it was suggested that a blood count be taken. He was found to have 40 per cent. hemoglobin. By June 11 it had reached 70 per cent., and so on June 13 he entered the hospital for operation, not in fine condition for extreme measures on the intestines, but still with a slight margin of strength for the necessary shock accompanying resection if that should be necessary.

Operation.—June 15, an incision was made along the right rectus over the tumor, and it was immediately seen that we had to deal with a tumor on the inside of the ascending colon. The incision was enlarged upward and across the rectus to afford space for intestinal anastomosis. The omentum was incised between ligatures tied about 1½ inches from its right border up to its junction with the transverse colon. The transverse colon was then clamped at the hepatic flexure and tied with a piece of gauze toward the median line. After a purse-string suture had been placed about it on the gauze side, the colon was cut through, the end puckered in with the purse string, and whipped over with catgut. This closed the distal end and the gauze was removed. The other end, after careful cleansing, was wrapped and covered with several layers of gauze for protection. This method was pursued because of the necessity of hurrying on account of the condition of the patient. The ileum was then prepared similarly about three inches from the ileocecal valve, but not severed. The omentum was reflected upward and the large end of a Murphy button was inserted in the usual way into the side of the transverse colon just below it. I took away a small area of the wall to prevent any chance of a later contraction of the new valve. The ileum was then divided, the other half of the button inserted into its proximal end and the union affected—a lateral implantation of the ileum into the transverse colon. After reinforcing the Murphy button with a continuous catgut suture, I drew the omentum down and lightly fastened it over the point of union with two or three fine catgut sutures, and also over the end of the closed colon. After cleansing the field well, the whole was dropped back into the abdomen, covered with a pad and seen no more. I then tied off the ascending colon, cecum, appendix, and stump of the ileum by ligating the mesentery from above downward with strong catgut, occasionally using clamps first. Only at the hepatic flexure did I have trouble from the vessels slipping from the grasp of the catgut, and this was readily controlled by passing a suture through the base of the mesentery. The wound was closed with through-and-through silkworm gut.

Result.—The patient reacted well. No symptoms of peritoneal irritation appeared. With the exception of a colon infection of the wound, apparently soiled by the open ends of the removed bowel, he made a very satisfactory recovery. The button passed on the nineteenth day. Food was given by mouth after the second day.

Examination of Tumor.—Examination of the tumor showed it to be a papilloma about the size of an orange situated on the outer side of the colon opposite the ileocecal valve, with its base undergoing malignant infiltration. An enlarged gland in the mesentery just beneath it was not involved in the malignancy, which speaks for a favorable prognosis in this case. The pathologic report, for which I am indebted to Dr. Mary Halton, showed the tumor to consist of many very light, branching, interlacing strands of connective tissue forming a papillomatous structure. These were all connected by a layer of cylindrical epithelium. In a few places the wall of the bowel had been penetrated, and similar branching connective structures covered with epithelium were found imbedded in altered muscular structure. In many places there were small collections of lymphocytes. The lymph gland showed hyperplasia with some hyperemia, and in places a catarrhal condition of the lymph sinus. No metastasis was seen in the gland.

The small amount of shock in this case, in which the patient was in such a condition as to be susceptible to considerable shock, I attribute to the small quantity of blood lost—every vessel being ligated before being severed—and, secondly, to the avoidance of unnecessary manipulation of the intestines and of undue exposure of them, but a very small amount being exposed at one time.

Few Castor Beans in Kansas.—According to the Kansas State Board of Agriculture, the growing of castor beans in Kansas may shortly cease altogether. The crop of 1904 amounted to only 2,925 bushels. In 1879 the yield 766,143 bushels.

THE CHEMISTRY OF THE PROTEID MOLECULE.

There are apparently three chief routes by which chemists may seek to learn the structure of the proteid molecule. First, by decomposing it, collecting the products of decomposition and studying their structure, quantity and possible groupings. Second, by splitting the proteid molecule step by step, so that the main groups can be determined and studied each by itself. Third, by synthesizing the proteid molecule. This, of course, is not to be done at one step, but first the ultimate splitting products are to be synthesized, then these joined to form the higher groups, and so on. Hopeless as this problem may seem to the practical physician, yet there are enormous energies directed toward its solution, and encouraging progress is undoubtedly being made. This, however, by no means implies that the goal is near. Two important centers of work on the structure of the proteid molecule are the laboratories of Emil Fischer in Berlin and of A. Kossel in Heidelberg and from each has recently appeared an article summarizing some of the features of the problem.[1]

By far the greatest amount of work has been directed to the isolation and study of the nitrogenous bodies that are split off when proteids are decomposed, as this is of necessity the fundamental study. Proteids in as pure condition as it is possible to obtain them are decomposed, by the action of acids or alkalies as a rule, instead of the digestive ferments, as with these are introduced other and unknown substances. To the earlier discovered and more generally known bodies, leucin and tyrosin, have been added more and more nitrogenous substances that also are split off from the giant proteid molecule which they go to form. Abderhalden gives the following list: Glycocol, alanin, aminovalerianic acid, leucin, isoleucin, phenylalanin, glutaminic acid, asparaginic acid, cysteïn, alpha-prolin, oxy-alpha-prolin, serin, tyrosin, tryptophan, lysin, aginin and histidin, not to mention other less studied substances. If we consider the possible ways in which such a number of substances, each in itself complex, can be arranged, we may have some insight into the difficulties of the problem and the enormous complexity of the proteid molecule. In addition must be considered the great obstacle due to the fact that at the present time we have no means of obtaining any proteid in a positively pure condition. Kossel, indeed, likens the proteid molecule to a great receptacle, filled with various organic compounds formed through the activities of the living organism. At one time it was believed that the differences between different proteids were chiefly external, and that one could be substituted for another in physiologic processes without important consequences. Now it is known that the proportion of the various components of the molecule may vary greatly. For example, arginin was found to occur in four different proteids in the following proportions—83, 40, 20 and 1.8 per cent. We therefore can not assume that proteid from muscle is of exactly the same effect and value as proteid from milk, egg white or grain. If we compare the composition of casein, the chief proteid supplied to the nursing infant, with the various proteids of the body it forms, it becomes evident that during the processes of digestion and assimilation very considerable changes must occur in the proteid foodstuffs. There is already considerable experimental evidence to support the theory that digestion of proteids in the alimentary tract does not stop with albumoses and peptones, but that they are always split up until they are no longer proteids at all, but relatively simple nitrogenous bodies similar to or identical with those obtained in experimental decomposition of the proteid molecule. These bodies are then combined again to form proteid molecules characteristic of the different tissues or organs of the body. Such a conception of the metabolism of proteid certainly fits best into the differences observed in the structure of the body proteids, as compared with the food proteids. If the food proteids remained as proteids in their course through the body, we could hardly expect them to be so greatly changed as they are in some instances when they form the body proteids.

The great diversity that exists in the composition of different proteid molecules is particularly well shown by the results of studies of the simplest forms of proteids, the protamins. In a series of seven different protamins eleven different nitrogenous bodies were found, and of these but two were present in all the protamins, eleven different nitrogenous bodies were six of the eleven bodies, and one contained but four. If such differences exist among the simplest proteids, what must the differences be among the most complex forms. We can no longer consider all proteids as having a *fixed and constant central body, the typical proteid molecule*, to which certain groups are joined to form the different varieties of proteids. Rather must we consider the proteid molecules as formed by the grouping of a large number of molecules of organic compounds, each characterized by containing nitrogen in various structural relations to the carbon, hydrogen and oxygen. In some proteids there are particular groups that are not present in others; in each the proportion of the constituent groups is different from that in any other sort of proteid.

---

ANTITUBERCULOSIS SERUM.

About a year ago, Marmorek made the startling announcement that he had succeeded in preparing a potent antituberculosis serum, but his claims were soon disputed by French practitioners of high standing. The high authority of the assailants of this new remedy caused it for a time to pass out of serious consideration, but it is gradually coming into prominence again as more favorable results from extended trials are being published in different parts of the world. Marmorek is convinced that tuberculin is not the true toxin of the tubercle bacilli which is responsible for the symptoms and for the anatomic lesions of tuberculosis. He believes that it is a bacterial product which, when injected into a tuberculous patient, causes the bacilli in the lesions to secrete toxin and thus to produce a rise in the patient's temperature. That being the case, we could hardly expect beneficial results from treatment with antituberculin serum and they have not been obtained. He has accordingly set out to obtain the true toxin in solution, and apparently has met with some degree of success, and is using this toxin in the immunization of horses. According to his views, the secretion of tuberculin and toxin are two functions that are not found in a culture of tubercle bacilli at the same time. The toxin is produced by the young organisms, while the older ones produce only tuberculin. In order to make the bacilli retain the physical properties of those in young cultures for a long time, and thus to augment their toxicogenic power, he grows them in leucotoxic serum which is prepared by immunizing calves against guinea-pig's leucocytes, by intraperitoneal injections. This leucotoxic serum he found to be a very fair culture medium for the production of toxin, but he was able to improve it somewhat by adding a bouillon extract of liver tissue. When a virulent culture of tubercle bacilli is grown in this serum-liver mixture, toxin is produced in such quantity that from 8 to 10 c.c. of the filtrate kills a guinea-pig of average size in about eight days. When horses are injected with these filtrates there are observed marked local and general disturbances, and their serum gradually acquires antitoxic powers, as is shown by the fact that from 15 to 20 c.c. of it protects a rabbit against an intravenous injection of tubercle bacilli. This dose of tubercle bacilli produces general tuberculosis and death when injected into normal rabbits.

Marmorek used his antituberculosis serum in the treatment of several cases of tuberculous meningitis, but observed only temporary improvement. In some cases of pulmonary tuberculosis the improvement seemed to be very striking. The serum was also used in cases of tuberculous pleuritis and tuberculosis of the spine with very encouraging results. In the former, the transudate was rapidly absorbed and the patient's general condition improved, while in the latter a complete cure was observed. In no case did the treatment appear to do harm. But very unfavorable reports were soon given out by Dieulafoy, Lucas-Championnière and Hallopeau. Recently, however, more favorable results have been reported by a number of French, German, English and Canadian clinicians. Latham,[1] for instance, reports five cases of pulmonary tuberculosis that improved under the serum treatment. Richer[2] reports seven cases, six of which improved and apparently got well, but the time is too short to say whether or not the improvement is permanent. The seventh case was in the last stages of the disease, and not much was expected from the injections. Richer believes, however, that they had an injurious effect, because the patient died thirty-six hours after the second injection. He advises, therefore, that the serum should not be used in the last stages of the disease. Frey[3] reports eight cases that were treated with the serum, six of which showed improvement. The other two cases were not benefited by the treatment, but there were no harmful effects other than slight local disturbances due to the injection of the horse serum. It would seem, therefore, that Marmorek's antituberculosis serum has some antitoxic properties, and as its use is in no way dangerous, it is desirable that it should be given more extended trials, as in this way only can its true value be determined.

The recent work of Friedman[4] on antituberculosis serum also is very interesting and encouraging. He isolated a culture of tubercle bacilli from a tuberculous lung in a turtle, and has shown that this culture is practically harmless for guinea-pigs and calves, but produces in them a fair degree of immunity against human and bovine tuberculosis. He immunized a cow with two injections of this organism, and later inoculated her intravenously with a large dose of bovine tubercle bacilli. This inoculation produced an acute fever, which subsided in a few days, and the cow showed no further signs of sickness. The control animal was very ill, lost weight, and the discharge from its nose contained tubercle bacilli. Three months after the inoculation both cows were killed, and the autopsy revealed general miliary tuberculosis in the control, while only a few healed tubercles were found in the bronchial glands of the immunized animal. Friedman also reports that a cow had acquired tuberculosis spontaneously, but recovered during the process of active immunization with the tubercle bacillus isolated from the turtle. He suggests that equally favorable results might be obtained with this treatment in cases of human tuberculosis. He has used this organism to produce an initial immunity in guinea-pigs and cattle, and was enabled to get a high degree of immunity in these animals later by using human and bovine tubercle bacilli. It must be remembered that it is difficult to produce an initial immunity in these animals if cultures from warm-blooded animals are used at the outset, because the animals usually die from the effect of the inoculations. The immune serum thus prepared protects guinea-pigs against a fatal dose of human or bovine tubercle bacilli, and Friedman hopes in this way to produce an antituberculosis serum of great clinical value.

THE MORTALITY AMONG PHYSICIANS IN 1904.

During 1904 we recorded the deaths of 2,142 physicians in the United States and Canada; a mortality of 17.14 per 1,000. The average age at death was over 60 years. The average length of practice was over 30 years.

These facts are based on a critical analysis of the list of deaths published week by week in The Journal. In this are now included not only the regular practitioners, but practitioners of the so-called "schools" which are recognized by state boards of medical examiners. Notwithstanding our persistent endeavors to obtain exact information, the statistics regarding these deaths are still incomplete. As illustrating this fact it may be said that in the notices of the deaths no cause was given, or the cause assigned was so obscure or so manifestly incorrect as to be valueless, in 954 cases, the age was not given in 421 instances, and the number of years of practice was omitted in 288 cases. During 1902 we chronicled the deaths of 1,400 regular practioners, during 1903, the deaths of 1,648 physicians, including the homeopaths and eclectics. Thus the mortality rates have been: 1902, 14.74 per 1,000; 1903, 13.73; 1904. 17.14. During 1904 the American Medical Association lost by death 166 members.

Heart disease leads the death causes with 205. These, of course, include the sudden deaths stated to have occurred from "heart failure," etc. Of the deaths due to cardiac disease, 16 were from angina pectoris and 3 from fatty degeneration of the heart. Cerebral hemorrhage, which includes the deaths from "paralysis," "apoplexy," etc., caused 179 deaths. Pneumonia heads the list of clearly defined diseases with 172 deaths, or 7.5 per cent. of the total mortality. Nephritis, including "kidney disease," was responsible for 91 deaths, and uremia caused 16. Tuberculosis is said to have been the cause of 90 deaths, all but 8 of which were from tuberculosis of the lungs. Cancer caused 39 deaths; typhoid fever, 37; septicemia, chiefly from operation wounds, 23; diabetes, 20; gastritis, 16; appendicitis and meningitis, 15 each; bronchitis and insanity, 11 each; hemorrhages and peritonitis, 9 each; asthma, influenza, locomotor ataxia, paresis, rheumatism and gangrene, 6 each; erysipelas, 4, and diphtheria and scarlet fever, 3 each. Of the total deaths, 143 were due to violence of one kind or another. Of these deaths, 95 are chargeable to accidents, 36 to suicide and 12 to homicide. Of the accidents, poison caused 21 deaths; railway accidents, 17; falls, 14; drowning, 10; street-car accidents, 8; runaways, 7, etc. Of the 36 physicians who committed suicide, 14 chose poison as the means; 11, firearms; 3, hemorrhages from cut arteries; 2, asphyxiation by gas; 1, drowning; 1, hanging. In 4 cases the method employed was not stated. During 1904, 12 physicians were murdered. This is 3 more than in 1903, and 1 less than in 1902. Of the 12, 10 died from gunshot wounds, 1 was stabbed, and in 1 case the cause was not stated.

The ages of the physicians who died varied between the limits of 22 and 104 years, the average being about 60 years. The greatest number of deaths—57—occurred at the age of 60; followed by 51 at the age of 70; 45 at the ages of 65 and 68, respectively; 43 at the age of 67; 41 at the ages of 75 and 76, and 40 each at the ages of 72 and 73. Above the age of 70, 596 deaths occurred; above the age of 80, 241 deaths; above the age of 90, 19 deaths; and 3 physicians had passed the age of 100, the oldest on record being 104 years old.

Notable among the dead are the following:

Dr. Hamilton Atchison West, Galveston, Vice-President of the American Medical Association in 1888, for twelve years secretary of the Texas State Medical Association, and an especial authority on malaria, typhoid and yellow fever.

Dr. Edmund Andrews, Chicago, scientist and pioneer in surgery and medical education.

Dr. William Barton Hopkins, Philadelphia, authority on fractures.

Dr. Roberts Bartholow, Philadelphia, whose "Practice of Medicine" and "Therapeutics" are standard works.

Dr. John Milton Duff, Pittsburg, Chairman of the Section on Obstetrics and Diseases of Women, 1894, widely known as a gynecologist, lecturer, teacher, writer, diagnostician and operator.

Dr. Ralph N. Isham, Chicago, one of the oldest and best known surgeons of the West, and one of the founders of the Northwestern University Medical School.

Dr. Frantz H. Coe, Seattle, president of the State Section on Nervous and Mental Diseases in 1904, and one of the most prominent young neurologists of the East.

Dr. N. S. Davis, Sr., Nestor of the American medical profession; one of the founders of the American Medical Association; first editor of The Journal; pioneer in scientific medicine, and a pillar of strength to the American medical fraternity.

Dr. Frantz H. Coe, Seattle, president of the State Board of Medical Examiners of Washington and of the Washington State Medical Association.

Dr. Samuel Warren Abbott, Boston, secretary of the Massachusetts State Board of Health, and an authority on vital statistics.

Dr. Alfred S. Wolff, for twenty-five years inspector and quarantine officer of the Texas State Health Department at Brownsville; expert on yellow fever.

Dr. James Anthony Dibrell, Little Rock, Vice-President of the American Medical Association in 1901, and twice president of the Arkansas Medical Society.

Dr. Henry Munson Lyman, Chicago, for many years senior dean of Rush Medical College and prominent as a neurologist.

GREATER PNEUMONIA MORTALITY IN FLATS.

The insanitary possibilities of the slum tenement house are sufficiently well known. Those of the average medium-priced flat we have already dilated on to some extent. Now it is reported that the pneumonia mortality is especially high in the high-priced apartment buildings—the tenements of the rich—in New York City. Every phase of excessive urban concentration seems to have its special unhygienic accompaniments.

HONEST MANUFACTURERS IN FAVOR OF THE PURE-FOOD BILL.

According to the Washington *Star*, a number of manufacturers of preserved food have communicated with Dr. Wiley, the chemist of the Department of Agriculture, pledging themselves to discontinue the use of any coloring matters or preservatives condemned by him. This is a favorable sign and a step in the right direction, but it does not lessen the necessity of the passage of the pure-food bill now before the Senate. It is an indication that such an act, if once passed, would be effective; what men can afford to do voluntarily will be still more likely to be done by others—if there is a penalty for not so doing. It shows that honorable manufacturers have no desire to oppose the passage of the act.

THE SYMPTOMATIC VALUE OF CHANGES IN THE NAILS.

Changes in the nails as a result of trophic influences have scarcely received the attention of which they appear to be deserving. It is true that the curvature of tuberculosis, the stunted growth of hemiplegia, the transverse marking after typhoid fever and the longitudinal striation attending myxedema have been described. In addition, the inflammation of syphilis is characteristic, while the nails sometimes suffer in conjunction with diseases of the skin, for example, favus, psoriasis, tinea. There is, therefore, good reason for believing that the nails may at times furnish evidence of the previous existence of disease perhaps not otherwise recognizable. Dr. E. Feer,[1] in a recent communication, calls attention to the formation of a transverse and somewhat curved line in the form of a groove or ridge on the nails, especially on those of the thumbs and the great toes, in the sequence of scarlet fever and measles. In typical cases of scarlet fever the phenomenon makes its appearance at the root of the nail four or five weeks after the onset of the disease, therefore at a time when desquamation is about completed. It becomes most distinct at the end of two months and it disappears at the end of six months, the natural period for the growth of the nail. The line is more prominent in proportion to the thickness of the nail and also to the intensity of the exanthem. The occurrence is referred to interference with the growth of the epithelial germinal layer of the root of the nail. In cases of measles, the line was observed under the same conditions as in cases of scarlet fever, although it was less pronounced and correspondingly less frequent. The presence of the line affords a means of estimating the time that has elapsed from the onset of the disease and it is thought to constitute a valuable diagnostic criterion. It would seem more likely, however, that the condition is not peculiar to any one disease, but it is probably associated with a considerable number, although perhaps most marked in connection with those in which the integument suffers in greatest degree. For this reason it may be more pronounced in cases of scarlet fever than in those presenting a less marked exanthem.

FATAL HYSTERICAL HEMOPTYSIS.

We are so accustomed to looking on hysteria as a disease attended only with symptoms of functional derangement that we do not always fully appreciate its true seriousness and occasional gravity. While it is now generally admitted to be a distinct morbid entity, its symptomatology is almost uncircumscribed, and its clinical manifestations are by some still thought to be not wholly free from intentional deception. Unfortunately, we are as yet unable to demonstrate the changes, cellular and chemical, that underly the hysterical disturbance, so that much, no doubt, is thus classified that has other origin. Contrariwise the error is not uncommonly made of confounding the symptoms of hysteria and those of organic disease. The hysterical symptom-complex in its protean variation is not rarely long continued, but fortunately the disease does not often terminate fatally. A remarkable case of this character, however, was recently reported by Dr. N. Pende[1] before the *Società Lancisiana* of Rome, death resulting from hemoptysis, for which no adequate organic cause could be discovered. A girl, 17 years old, who had lived with a sister, now dead of pulmonary tuberculosis, attended with repeated hemoptysis, developed in the sequence of emotional disturbance pulmonary hemorrhage, in conjunction with cough, pains in the chest and fever. On examination, distinct hysterical stigmata were discovered, as well as signs of congestion at the apices of the lungs. Neither elastic fibers nor tubercle bacilli were found in the sputum, inoculation of rabbits with which also yielded negative results. There was, however, a reaction on the part of the patient to tuberculin. The symptoms were considered hysterical, and fever, cough and hemoptysis yielded to suggestive treatment. The patient was dismissed as cured, but the hemoptysis recurred after several days and death followed in the course of a few hours. No anatomic alterations could be discovered on postmortem examination either in the lungs or in other organs that could be considered capable of causing the hemoptysis. The phenomenon accordingly is attributed to vasomotor influences.

TRUTH AND POETRY CONCERNING URIC ACID.

I.

In the slow but steady advance which medicine is making, new facts are often established for a long time before they meet with general acceptance, and old theories have had their foundations washed out from under them years or decades before their fallacies have become generally recognized by the profession. It is easy to be too severe in criticizing the inertia of medical men in this respect, for the very conservatism which accounts for the facts mentioned has gone far to protect our guild from the too speedy welcoming of immature conceptions, on the one hand, and from the too easy rejection, on the other, of theories which, under assault by partisan or ignorant critics, prove ultimately to be sound. It is not an unwillingness to accept new truth nor a desire stubbornly to retain error which is characteristic of our profession. On the contrary, it is rather the fear of being duped concerning the new or of being cheated of old and well-tried good which animates it and determines its action or inaction.

Now that the media of communication among physicians have been so marvelously multiplied, it may be urged that the excuse for a continuance in ignorance regarding medical facts and theories is not what it formerly was. Medical journals are, it is true, more widely read than ever before by the profession; the nations, through the activity of collective reviews and international periodicals, have been brought closer together than at any previous time; were the increased information brought to medical readers always reliable, the profession's knowledge ought to be advanced by leaps and bounds. Unfortunately, at a time when everybody writes, the views which are expressed in the various medical journals are so contradictory that the mind without a special scientific training often becomes confused, knows not what to believe, and naturally settles down on the convictions which suit its own inclination best or on statements which have been gained from some authority for which it has a particular predilection. The preliminary training which the average medical man has obtained hitherto in subjects like chemistry, physics and biology has been totally inadequate, when discussions involving disputes in these domains are brought to his attention, to permit him to form sound judgments concerning them. A further difficulty for the medical man in practice lies in the inequality of the articles which are admitted to the pages of even those medical journals which he has been taught to regard as the best. So disparate are the views expressed in different articles in the same number of a given journal that the average medical mind often turns from the reading of them with a feeling of uncertainty, if not of disgust.

It is one of the objects of The Journal in its editorial pages to present, from time to time, as accurately as it can, synopses of the real advances which take place in medical research. It is and has been its endeavor to promulgate as firm convictions in these columns only those views which receive the support of what it regards as the soundest medical judgment of the time. The wisest may err, and there can be no doubt that, even when the greatest care is exercised, an erroneous opinion may occasionally be supported or a faulty judgment passed. Should this occur, The Journal would be the first to regret it, and it would seize the earliest opportunity to correct it. Its readers may rest assured, however, that no pains are spared to prevent the expression of opinions other than those which represent the sanest medical thought of the day.

One of the subjects in which the growth of our conceptions has been extremely slow, but about which, to-day, our real knowledge far outruns the general professional recognition of it, is that which has to do with the origin, fate and significance of uric acid in the body. The Journal has, on several occasions, called attention to progress in knowledge in this field; it has warned against many of the fallacies which persist, and it has urged the profession to revise views which, though long taught, have been proved to be without firm foundation. The false ideas concerning the mode of formation of uric acid in the body, its decomposition and its pathologic significance have become so deeply rooted, not only in the professional mind, but to a certain extent in the mind of the laity, that it is unusually difficult to eradicate them. The perpetuation of erroneous ideas has been helped no little by facile publications like those of Haig, wherein, doubtless with good intentions and assuredly with great enthusiasm, doctrines have been advocated which are based partly on faulty or misinterpreted observations of others, partly on unskilled and non-scientific personal experiments. When such ideas happen to harmonize with the interests of an unbridled commercialism[1] which floods the country with highly colored and sensational reports of marvelous cures by so-called antilithics and uric-acid solvents, it is easy to understand how the attempt may be made by those who have vested interests to prolong the drowsiness of the profession and the laity, and how any effort made to awaken the somnolent may excite antagonism.

A considerable body of definite facts has now been established concerning uric acid. We really know a great deal about its origin, the transformations which it undergoes and the way it is excreted. We are beginning to know something of its significance, though far less, it must be admitted, than many people imagine. It is our intention to review, thoroughly though succinctly, the mass of work which has been done on the subject. We shall try to sift out the wheat from the chaff, and shall make an effort to distinguish what is the truth from what is mere poetry in this matter. In our next issue we shall begin with a review of the doctrines which have been held regarding the formation of uric acid in the body; in succeeding numbers of THE JOURNAL we purpose taking up the normal fate of uric acid in the tissues, the facts bearing on the localization of the processes of uric-acid formation and decomposition, the chemical and physical properties of uric acid and urates, including the conditions of solubility and precipitation, and, finally, the relation of uric acid to pathologic processes.

---

[1] Since this was written The Journal has received a letter from a firm which has been advertising a "uric-acid solvent." This letter is a reply to a circular sent out by the advertising department; it bears so directly on the point mentioned that we quote a part of it: "Should we place an 'ad' with you, it would be to exploit a proprietary preparation for the relief and cure of the uric acid diathesis. It has been made apparent to us that it is the avowed policy of The Journal to discourage the use of all proprietary preparations, and under date of August 20 The Journal in an editorial made a very sarcastic, if not unethical, attack on the uric acid diathesis. We concede to any physician the right to his personal opinion on this subject, and to any journal the right to publish any views which may be held by its editors, but when such views tend to discourage the profession in the use of uric acid solvents and eliminants, it certainly impairs the value of its advertising pages as a medium through which the manufacturer of a uric acid remedy may reach the profession. This is an additional reason why we now decline to use The Journal through which to advertise ———."

The literature on the subject is immense. One has only to glance at the collective bibliographies of the subject which have been prepared, for example, that of Wiener, to realize the magnitude of the task which a careful historical review necessitates. It would be impracticable as well as undesirable to marshal all the authorities in the review of the subject which we intend to make for our readers; it will suffice if we point out the most important steps which have been taken as knowledge of the subject has advanced. We believe that such a historical presentation, though it will be full of surprises for many, is the best means of making clear to the profession at large the true status of the questions at issue.

Medical News.

DISTRICT OF COLUMBIA.

Health of District.—The report of the health officer for the week ended December 31 shows the total deaths to have been 122. There were 119 births and 13 still births. At the close of the week there were under treatment 45 cases of diphtheria, 39 of scarlet fever, 172 of typhoid fever and one of smallpox.

Puerperal Arthritis.—At the meeting of the Washington Obstetrical and Gynecological Society, held on January 6, Dr. Edward E. Morse read an essay on puerperal arthritis. He took the position that all cases of puerperal arthritis are caused by sepsis and that the so-called puerperal rheumatism is puerperal sepsis.

Municipal Hospital.—The district government is about to build a municipal hospital at a cost of $250,000. The plans presented in competition by Frank Miles Day of Philadelphia were accepted. Congress has been asked to appropriate $150,000 additional to accommodate several hundred tuberculous patients who are barred from other hospitals.

ILLINOIS.

Fire in Hospital.—A fire which broke out in the hospital of the Illinois State Reformatory, Pontiac, caused damage estimated at $3,000. Of the 40 patients all were taken out safely.

State Teachers and Tuberculosis.—At the meeting of the State Teachers' Association at Springfield great interest was manifested in the exhibits of the State Board of Health showing the prevalence of tuberculosis in the state and its mortality as compared with that of other diseases. The association unanimously voted to indorse the efforts of the State Board of Health and to assist in the supervision of consumption by the dissemination of knowledge concerning the disease, the prevention and cure.

Personal.—Dr. H. C. Howard, Champaign, has gone to Florida for the winter.——Dr. and Mrs. Harry H. Whitten, Peoria, have returned from Europe.——Dr. William Engelbach, Arenzville, has returned from Europe.—Dr. George A. Clotfelter, mayor of Hillsboro, has been appointed local surgeon for the Big Four System.——Dr. Paul G. Manley, Mount Carmel, while driving across a railway track, was struck by a train, his buggy was demolished, but he escaped with severe contusions.——Dr. Milton Jay, Chicago, has been re-elected president of the Association of Chicago & Eastern Illinois Railway Surgeons.

Chicago.

Smallpox.—During the week ended January 7, 18 cases of smallpox were sent to the isolation hospital. Of these 12 had never been vaccinated and 6 had old scars.

Deaths by Violence Decreased.—During 1904 there were 542 less deaths from violence than in 1903. There were 59 fewer suicides, 7 fewer murders and only 8 more railroad deaths and 6 more street-car fatalities than in 1903.

Tuberculosis in Office Buildings.—Dr. W. A. Evans in a talk on consumption before the union of janitors and window-washers, said that ventilation of office buildings was not properly secured and that unventilated rooms furnished ideal breeding places for the germ of the disease. He urged the abolition of dry sweeping.

Deaths of the Week.—During the week ended January 7 there were 542 deaths, equivalent to an annual mortality of 14.19 per 1,000. All the important causes of death show decreases, the most marked in consumption—from 68 to 41, and the total from all causes is nearly one-fifth (19.7 per cent.) lower than that of the week before.

MARYLAND.

Baltimore.

Dinner to Dr. Bosley.—The employes of the health department entertained Dr. James Bosley, health commissioner, with a banquet, December 27.

Personal.—Dr. Thomas C. Bussey has been elected physician to the almshouse, and Dr. J. Royston Green, physician to the county jail of Baltimore County.——Drs. Randolph Winslow and J. Mason Hundley paid a visit to Dr. Mayo's Hospital, Rochester, Minn., last week, returning January 1.

Mandamus Proceedings Dismissed.—Dr. Campbell F. Flautt instituted mandamus proceedings some time ago in the Court of Common Pleas to compel the State Board of Examiners of the Medical and Chirurgical Faculty to issue him a license to practice medicine in Maryland. The mandamus was dismissed by Judge Stockbridge December 20.

Concerning Dr. Osler.—The *Maryland Medical Journal* has issued a booklet containing a portrait of Dr. Osler and comments from different sources on his resignation.——The committee on the Osler testimonial has appointed a subcommittee of 50 to canvass the profession of the city, each one seeing 10 doctors.——The twenty-ninth anniversary of the foundation of the Johns Hopkins University will be celebrated February 22. Dr. William Osler will deliver the principal address, probably his last public address before he leaves America.

MASSACHUSETTS.

Leper Colony.—The Massachusetts State Board of Charities has bought land in Harwich, a town on Cape Cod, for the establishment of a "leper colony" to accommodate the three patients now within the limits of the state. Very vigorous protests are being made from all the surrounding towns.

Sanitation of Cities.—Prof. William J. Sedgwick, professor of biology and lecturer on sanitary science and public health in the Massachusetts Institute of Technology, Boston, will give a course of ten free public lectures before the Lowell Institute on Monday and Thursday evenings, beginning January 9, on "The Sanitation of Cities."

Made a Test Case.—In order that the case might go to the Supreme Court, the judge in the Superior Civil Court at Dedham ordered a formal verdict for two children who brought suit for $10,000 each against the town of Hyde Park because they were denied school privileges, owing to a failure to be vaccinated. One hundred and fifty dollars was allowed the girl and $50 to her brother.

Home for Crippled Children.—The last legislature voted $300,000 for the purpose of building and maintaining a home for crippled and deformed children. The board appointed by the governor to have charge are Drs. Edward H. Bradford, William A. Morrison of Boston, and Messrs. William Endicott, Jr., Leonard W. Ross and A. S. Pinkerton. The board organized with Dr. Bradford as chairman.

Milk Examination.—Examinations of Boston's milk supply made by the Board of Health during last summer showed that over 46 per cent. of the samples taken were warmer than the legal limit of 50 F.; 27.5 per cent. of the samples had more bacteria than the law allows, 500,000 to the c.c. Of these 9.75 per cent. had betwen 500,000 and 1,000,000, 12.75 per cent. between 1,000,000 and 5,000,000, and 5 per cent. more than 5,000,000.

The Question of Cancer.—The statement that only San Francisco exceeds Boston in its total annual deaths from cancer, and that while the former had in 1903, 103 deaths per 100,000 of population the latter had 85, is explained by the Board of Health on the basis that more careful mortality records are kept in Boston than in many other large cities. They maintain that the disease is not more prevalent than elsewhere. It is said that the report of the cancer investigation carried on at Harvard Medical School by Dr. E. H. Nichols for the past two years under the Crofts bequest of $100,000, will soon be published and will show that no etiologic factor except heredity is well established.

NEW YORK.

Fire in State Hospital.—Fire was discovered in ward 2 of the Middleton State Hospital. After flooding the floors the fire was subdued.

Liberal Gift.—The Syracuse Hospital of the Good Shepherd received a New Years gift of $50,000 from William B. Cogswell, who has previously contributed large sums to the support of the institution.

Personal.—Dr. Mary Clayton has resigned from the staff of the St. Lawrence State Hospital to accept the position of woman physician at the Craig Colony for Epileptics, Sonyea. ——Dr. Charles W. Clendenan has been appointed city physician of North Tonawanda.

Crippled Children's Hospital.—The New York State Hospital for the Care of Deformed and Crippled Children, Tarrytown, will move about April 1 to its new site at West Haverstraw, for which $50,000 was appropriated by the last legislature. During the year ended Sept. 30, 1904, 17 new patients were admitted, making a total of 42 patients treated during the year.

For an Inebriates' Home.—A bill has been prepared which will be presented to the legislature for the establishment in New York City of an inebriates' home, where there will be free treatment of alcoholism and drug habits. The home as planned will be built from money received from the excise law. It is estimated that about 1,000 patients would be found for such a home at once. The management would be under the mayor with a board of medical advisors.

The Governor's Message.—In his annual message Governor-elect Higgins says concerning the insane:

> The management of the state hospitals for the insane, fourteen in number, with a total number of patients on Oct. 1, 1904, of 25,019, was completely centralized by legislation of 1902 abolishing the boards of managers of the various hospitals and leaving with the commission on lunacy complete jurisdiction, both as to financial control and internal administration. The advantages of centralized control of the financial operation of the hospitals are evident. It is of the utmost importance, however, that this great system of hospitals, involving the expenditure of so large a sum of money annually, and the care of so many thousands of peculiarly unfortunate and defenseless persons, should rest on a broad basis of public interest and public confidence and should retain the coöperation of philanthropic citizens throughout the state. In my opinion this can best be secured by leaving the control of all financial matters, as at present, in the hands of the commission, and by providing for each hospital a board of managers, in general charge, through the superintendent, of the internal affairs of the hospital.

He also favors the enlargement of the present hospital and the establishment of a new state hospital. He also advocates a separate building in each state hospital for the treatment of acute insanity. He protests against the commitment as dependent insane of those who are not properly state charges and who have property or relatives legally chargeable for their support and maintenance. He recommends that before any insane person is permanently received in a state hospital as a state charge the question be judicially investigated and determined whether such person is a pauper without relatives chargeable with his support and able to contribute thereto. He also recommends increased accommodations for the feeble-minded and that all sources of public water supplies be examined and analyzed at frequent intervals and that the private water supply of public resorts should also be subject to state analysis and the results should be made public. A system of state inspection of domestic water supplies to be maintained at the cost of the municipalities, corporations and private owners is recommended. A state water storage commission, having also for its object the supply of water to the cities, might be of great service. He further states:

> The court of appeals has finally upheld the constitutionality of the Tenement House Law of 1901, which has been contested by the courts. This measure is one not only of charity but also of justice; not only for the benefit of the poorest families but also for the general welfare of the community. For its enactment and enforcement my predecessor (Governor Odell) is entitled to the highest credit. The law is now definitely established.

New York City.

Crusade Against Voodoo.—Through its counsel the New York State Medical Association has begun a crusade against voodoo doctors of the East Side of New York City.

Contagious Diseases.—There were reported to the sanitary bureau for the week ended Dec. 31, 1904, 434 cases of tuberculosis, with 134 deaths; 302 cases of diphtheria, with 45 deaths; 206 cases of scarlet fever, with 16 deaths; 126 cases of measles, with 6 deaths; 52 cases of typhoid, with 7 deaths; 87 cases of varicella, and 18 deaths from cerebrospinal meningitis.

Tenement House Sanitation.—The tenement house commissioner, in his annual report to the mayor, says that of 48 blocks in the Thirteenth Ward there are only seven in which there were no deaths from tuberculosis in 1904. Of 1,100 sanitary inspections made, from January 1 to October 1, the conditions discovered led the department to file 684 violations against tenement houses in this ward.

Death Rate Increased.—The death rate per 1,000 in Greater New York for 1904 was 20.32, an increase of over 2 per cent. over 1903. There was an alarming increase in the number of deaths from pneumonia and bronchitis, deaths from this cause numbering 14,518. There was also an epidemic of cerebrospinal meningitis which killed 1,211, while in 1903 there were only 271 deaths from this disease. During the year there were 55,195 violent deaths.

Bellevue Hospital Overcrowded.—Records show that the total number of admissions to Bellevue in 1904 was 28,925, the highest number the hospital has ever received. This is nearly 5,000 more patients than were received five years ago, with the same accommodations. The recent order compelling the physical examination of patients has entailed an increase in the house staff from 43 to 48. The additional influx has compelled many to sleep on mattresses on the floors and the accommodations for the house staff have been proportionately reduced.

Buffalo.

Hospital Opened.—Mercy Hospital has opened its doors for the reception of patients.

Measles Epidemic.—The measles epidemic continues at Buffalo. In some school houses the attendance of classes is reduced 50 per cent. No school has entirely escaped the epidemic. There were 1,200 cases of measles reported last month and the average number reported each day to the Health Department is 40.

School Inspection.—Dr. M. Elizabeth Schugens recently read a paper entitled "Medical Inspection of Schools" before the Women Teachers' Association. She embodied in her paper a report of various large cities where medical inspectors are employed to visit schools, such as Boston, New York, Philadelphia and other cities. In the public schools of these cities the medical inspector visits the primary grades every morning and examines children who have been pointed out by the teachers as unfit for class work. If the medical inspector finds the child ill, it is sent home, given a sealed envelope containing a letter to the parents, stating the child's ailments and recommending that the family physician be called. Often children go to school in the first stages of an infectious disease. Here medical inspection is a safe barrier, and also to determine the safe time for a child convalescing from contagious disease to return to school. Boston was the first city to inaugurate the medical inspection of schools and Buffalo will, it is hoped, soon follow this excellent example and institute regular medical school inspection.

OHIO.

New Hospital at Lima.—The commission chosen to select a site for the proposed new state hospital for the insane unanimously selected Lima after a two days' session. The Dunn farm was the site chosen, about one mile north of the city and consisting of 620 acres.

Welch in Cincinnati.—Dr. William H. Welch of Johns Hopkins University represented his college at the inauguration exercises held in Cincinnati in honor of Charles W. Dabney, president of the Cincinnati University. During his visit Dr. Welch addressed the students at the Cincinnati Hospital. A general reception was given in his honor by Dr. Joseph Ransohoff.

Society Election.—At the annual meeting of the Marion County Medical Society the following officers were elected: President, Dr. Charles E. Sawyer; vice-president, Dr. Lewis D. Hamilton; secretary, Dr. Dana O. Weeks; treasurer, Dr. Clyde R. McKinniss; censors, Drs. Joel B. Taylor and C. T. Wiant, and delegates to the Ohio State Medical Association, Drs. Robert C. M. Lewis and A. Melville Crane, all of Marion.

City Will Investigate.—The ordinance introduced several weeks ago providing for the expenditure of $2,000 to employ agents to investigate the books and management of the Cincinnati Hospital, has, on recommendation of the finance committee, been indefinitely postponed. In its place a resolution was adopted authorizing the expert accountants employed in the office of the city auditor to make the investigation.

Cincinnati Hospital at Avondale.—It has been finally decided by the Board of Public Service by a vote of 4 to 1 that the new Cincinnati Hospital will be erected at Avondale, a suburb of the city. The hospital grounds will occupy about 25 acres, away from the noise and smoke of the city. The pavilion plan, two or three-story buildings, has been decided on as the most feasible, and the entire structure is expected to accommodate about 750 patients, thus providing sufficient facilities for a number of years to come. There will, of course, be emergency hospitals situated in the city proper. The estimated cost is more than $1,000,000. Architects have already begun the plans.

PENNSYLVANIA.

Third Donation.—The sum of $500 has been donated to the West Chester Hospital by a "friend." This is the third successive year this friend has thus remembered the institution.

Personal.—Dr. Alford H. Read, Norristown, has been appointed coroner's physician.——Dr. Albert E. Osborne, West Chester, has moved to California, where he will resume medical practice.——Dr. Charles B. Noecker has been appointed surgeon in the police department of Scranton.

Philadelphia.

Physician Fined.—Dr. Charles M. Burk, who was arrested by the Board of Health for delaying properly to report a case of smallpox, was fined $5 in the magistrate's court.

Children's Hospital Report.—The Children's Hospital of the Mary J. Drexel Home treated 573 patients during the year; of these 340 were treated free. There were 381 surgical operations, 11,223 nursing cases and 10,446 clinic cases. Out of 65 cases of typhoid fever one patient died, and out of 71 cases of appendicitis operated on, none died. The expenditures of the institution during the year were $58,294.34.

Personal.—Dr. Wharton Sinkler was elected a member of the board of trustees of the University of Pennsylvania, to take the place of Dr. W. Howard Furness, resigned.——Dr. Sinkler has also been elected a member of the board of managers of the Episcopal Hospital.——Dr. Alfred Gordon has been appointed by Dr. Edward Martin, director of the health bureau, examiner of the insane in the Philadelphia Hospital.

Work in Hospitals.—During December the following patients were treated in the different hospitals of the city: Three hundred and nine cases were admitted to the wards of the Pennsylvania Hospital, and 1,600 to the receiving ward; there were 999 new patients treated in the dispensary, and 3,552 return visits were made. The Howard Hospital admitted 31 patients, treated 152 accident cases, and 514 new cases in the dispensary. The Charity Hospital treated 647 patients.

War on Tuberculosis.—Dr. Alexander C. Abbott, chief of the Bureau of Health, has issued a circular letter asking the physicians of the city to co-operate with the health bureau by reporting all cases of tuberculosis which come to their knowledge. He explains that tuberculosis is not regarded, however, with the same concern as are the acute transmissible diseases, and is, therefore, not subjected to the same official supervision. Nevertheless, for the protection of the public health, it is essential that cases of tuberculosis be kept under sanitary supervision. For the information of the health board appropriate blanks will be furnished the physicians for properly reporting this class of cases.

Busy Year for Coroner.—A summary of the work done by the coroner's staff during the year just closed shows that 3,467 inquests were held. During the year 1903, 3,357 were held, indicating an increase of 110. There were 4,969 cases investigated and 703 postmortems made. The largest number of deaths resulted from railroad accidents, 204 being attributed to that cause. The deaths classified with the fatal casualties aggregated 1,065. There were 209 suicides and 43 homicides. Heart disease was responsible for 148 deaths; burns and scalds, 148; drowning, 99; gunshot wounds, 52; asphyxiation, 87; malpractice, 38; poisoning, 21; infanticide, 2; alcoholism, 25; exposure, 3; heatstroke, 2; lightning, 1; electric shock, 6, and starvation, 1.

Health Report.—The total number of deaths for the week reached 478, as compared with 656 for the corresponding period of last year, and 497 during last week. The deaths from pneumonia during the week showed a decrease, 62 being reported, as compared with 69 last week and 89 in the preceding week. Typhoid fever is on the increase, 99 cases being reported, an increase of 26 over the preceding seven days. There were 256 cases of contagious disease reported, with 25 deaths, as compared with 223 cases and 21 deaths for the week previous. There were 8 deaths from typhoid fever, 14 from diphtheria, 64 from tuberculosis, 22 from cancer, 19 from apoplexy, 56 from heart disease, 62 from pneumonia, 19 from enteritis and 36 from Bright's disease.

Pulmonary Diseases in 1904.—Pneumonia heads the list of fatal maladies in this city, with consumption a close second. The total number of deaths from pneumonia during 1904 aggregated 3,360, as compared with 3,107 from consumption. Much of the pneumonia is attributed to the cold, damp trolley cars. Notwithstanding that death has been frequent from pneumonia and consumption, the health of the city is regarded good. The total number of deaths during the year reached 25,972, which is an increase of 25 over 1903. The death rate per 1,000 inhabitants for 1904 was 18.44, as compared with 18.82 in 1903. The deaths from pneumonia in 1904 show an increase of 180 over 1903, and the total reached 3,180. The deaths from consumption in 1904 exceed those of 1903 by 54. Deaths from typhoid fever in 1904 reached 744, which is 213 less than during 1903, while the deaths from smallpox last year were 229, a decrease of 49 from the figures of 1903.

College of Physicians Elects Officers.—At the regular meeting of the College of Physicians, January 5, practically all the former officers were re-elected for the coming year, as follows: President, Dr. Arthur V. Meigs; vice-president, Dr. James Tyson; censors, Drs. Richard A. Cleeman, S. Weir Mitchell, Horace Y. Evans and Louis Starr; secretary, Dr. Thomas R. Neilson; treasurer, Dr. Richard H. Harte; honorary librarian, Dr. Frederick P. Henry; councilors, Drs. DeForest Willard and John H. Gibbon; committee on publication, Drs. Gwilyn G. Davis, Thompson S. Westcott and William Zentmayer; library committee, Drs. George C. Harlan, Francis X. Dercum, Charles A. Oliver, William J. Taylor and S. Weir Mitchell; committee on Mutter Museum, Drs. John H. Brinton, George McClellan and J. Alison Scott; hall committee, Drs. John K. Mitchell, Thomas H. Fenton, B. Alexander Randall, E. Hollingsworth Siter and Aloysius O. J. Kelly; committee on directory for nurses, Drs. Wharton Sinkler, James C. Wilson and James V. Ingham.

GENERAL.

Yellow Fever in Panama.—Six cases of yellow fever are reported in the Panama canal district. The disease is endemic in this vicinity, but no cases have occurred recently until these now reported.

Election of American Physiological Society.—At the annual meeting in the physiological laboratories of Jefferson Medical College, Philadelphia, December 28, the following officers were elected: President, Dr. William H. Howell, Baltimore; secretary, Dr. Lafayette Mendel of Yale; treasurer, Dr. W. D. Cannon of Harvard. The members of the society were entertained at luncheon after the meeting by Dr. Henry C. Chapman.

Fake Drug Concerns.—Dr. William H. Wiley, head of the United States Bureau of Chemistry, in addressing the Society of Chemical Industry, New York, said that there were in the United States no fewer than 5,000 fraudulent drug manufacturers who should be put out of business. During the past year he said fifty such firms had been put out of business for selling or for advertising "fake" medicines. His own name had been used without his permission by one firm in an endorsement of its goods. When he protested he was told to mind his own business. However, he forced the firm to refrain from using his name.

CANADA.

Montreal Hospitals Filled.—Montreal is suffering from an abnormal amount of sickness at the present time. The various hospitals of the city have been overtaxed and there is no immediate indication that relief will come. In the Montreal General Hospital there is room for 202 patients, but 210 have been in residence. The number of patients in the institution on Dec. 31, 1904, was 191.

Contagious Diseases in Toronto.—During December, 1904, there were 227 cases of diphtheria in Toronto, as against 173 cases in the corresponding month of 1903; of scarlet fever there were 50 cases, as against 23 a year ago; of typhoid fever 14, as against 16 a year ago. The total number of cases reported during the year were as follows: Diphtheria, 1,360; scarlet fever, 318; typhoid, 133, as against 1,103, 699 and 156 for 1903. The deaths in December, 1904, were: Diphtheria, 17; scarlet fever, 1; typhoid fever, 6. The total number of deaths in 1904 from diphtheria were 125; scarlet fever 12; typhoid fever, 41; smallpox, 2, as against 136 for diphtheria, 100 for scarlet fever, 41 for typhoid fever and one for smallpox in 1903. The death rate from scarlet fever in 1904 was the lowest in six years.

FOREIGN.

Million to Charity.—Lord Mount Stephen has given over $1,000,000 to the King's Hospital Fund in England.

City Sanitarian.—The municipal authorities of Stettin, Germany, have installed a city "hygieniker," with a salary of nearly $2,000.

New Hospital in Rome.—The cornerstone has been laid of a hospital for the English-speaking residents of Rome. It is located on the Coelian Hill and has been endowed by contributions from many Americans and Englishmen.

Proprietary Medicines in New Zealand.—A bill has been brought before the New Zealand parliament to make it compulsory that all patent medicines sold in New Zealand place before the public the composition of the remedy sold. This will affect a great many from the United States.

Trachoma in London.—It is reported that so great is the rush of Russian Jews arriving in London suffering from trachoma, that the hospitals are turning them away. A large number of these persons are en route to America, while others have been rejected by the United States immigrant inspectors and having been returned by the steamship companies, are stranded in the United Kingdom instead of being sent back to Russia.

An Ophthalmologist at the Seat of War.—A. Moltrecht writes from the front during October that typhoid cases are numerous notwithstanding the almost wintry weather. He has encountered a number of interesting bullet wounds of the eye, among them several in which the bullet traversed the orbit, nose and mouth, or else passed out along the roof of the orbit, without injuring the eyeball. In several cases the bullet had injured the optic nerve, but the subject recovered without permanent functional disturbances, which is certainly, he adds, the *ne plus ultra* of a "humane" bullet.

American Hospital in Korea.—A new hospital building has been dedicated in Seoul, Korea, to be conducted under the direction of the Presbyterian Board of Foreign Missions. The first operation was performed in the new building on Oct. 4, 1904, and was for the extraction of cataract, one of the workers characterizing it as an especially appropriate one, that the first important work of a new missionary hospital should be an operation for "letting in the light." The entire cost of the building was defrayed by L. H. Severance of Cleveland, Ohio, and the hospital will be known as the Severance Memorial Hospital.

Joke Taken in Earnest.—A German daily paper has republished one of the satires from the burlesque number of the *Münchener med. Wochenschrift*, taking it in earnest or pretending to do so, and commenting drastically on it. The satire purported to be an ad. from a medical graduate seeking a place as substitute for a physician where he would have an "opportunity to learn something of obstetrics, of which at present he has not the faintest glimmer of knowledge." The daily paper cites the ad. as a "picture of the times" and comments on the audacity of the fledgling physician in thus offering his services to experiment on human beings as if they were laboratory rabbits. The editor of the lay paper in question is chairman of the local sickness-insurance companies (Krankenkassen), at Leipsic, where there has been, and is still, considerable friction between the Kassen and their medical officers.

Congress of Hygiene of Habitations.—The United States Public Health and Marine-Hospital reports state that the International Congress of the Hygiene of Habitations was inaugurated at Paris, November 3, in the amphitheater of the school of medicine, being the first reunion for the purpose of technical engineers, hygienists, and representatives of the great cities. At the opening meeting the French minister of public instruction, M. Chaumie, presided and, in his address to the congress, called attention to the special importance of the regulation of dwelling places as a protection against contagious diseases. Senator Strauss reviewed the means at the disposal of engineers and architects based on the medical knowledge gained in the campaign against tuberculosis, a malady notably perpetuated and diffused by faulty construction of houses. He affirmed that it is to-day inexcusable for a government or municipality to fail to interest itself in the question of tuberculosis, a disease whose principal foci of contagion are found in insalubrious homes. Representatives of numerous cities, especially prominent being the envoys of Berlin and Prague, addressed the congress. A section of the congress devoted its attention to floating habitations, namely, ships of every kind.

Recent Decisions of the Prussian Medical Court of Honor.—One of the decisions was in respect to the sale of an ophthalmic practice. The court decreed that it is incompatible with a profession carrying with it such responsibility and founded on a basis of scientific training to have a medical practice transferred from one physician to another for a pecuniary consideration. Another decision was in the case of a Berlin physician who had an office at his residence in a suburb and another office in the city. The regulations state that a physician can not have an office in two places already provided with other physicians. This regulation was meant for small towns, and it was decided that it did not apply to an office in a city with a suburban home. In the present case the physician was intending to give up one office as soon as his practice in the other would warrant it. Another physician was fined for professional association with a charlatan, and another for writing a letter to a colleague in which he referred to a third physician as having made a blunder in diagnosing, and commented on his nervous instability and morbid ideas, concluding with the statement that the writer could no longer have any respect for him as a colleague. The court further decided in another case to impose a fine on a physician for carelessly signing a certificate. He failed to state that he had no personal knowledge of the preceding circumstances, but merely reported them from hearsay. A certificate made out in this way is incompatible with the honor of the profession, and the physician was fined the costs.

Medical Prizes Awarded at Paris.—The particulars of the prizes offered by the Académie de Médecine and Académie des Sciences at Paris have been given in full in these columns from year to year. Many thousands of dollars are thus distributed annually, the competition for nearly all the prizes being open to the world. Full details were given in THE JOURNAL Jan. 24, 1903. The reports show that few physicians from outside France compete for the medical prizes. The only non-Frenchmen among the recipients this year were Christiani of Geneva, whose work on thyroid grafting received a prize; Odier of Geneva; A. Raffray of Mauritius received the Godard prize for a work on neurology, and Muskens of Amsterdam received honorable mention in connection with another. The great Audiffred prize offered for the discovery of a sovereign remedy for tuberculosis is an endowed annual income of $4,800. The income was divided among several recipients this year, including A. Delille for his research on the toxins of the tubercle bacillus in tuberculous meningitis and in tuberculosis of the nerve centers; and Nattan-Larrier for his work on the cultivation of the tubercle bacillus by injecting suspicious fluids into the nipples of guinea-pigs suckling young. The bacilli colonize readily in the secretion where they can be easily detected, while the inoculation induces a tuberculous mammitis. Two prizes were awarded to A. Monprofit of Angers, vice-president of the Société de Chirurgie, for a work on surgical affections of the ovaries and tubes, which also received a prize from the other Académie. No articles were received in competition for five of the prizes, offered for the best work on cirrhosis of the liver, arteriosclerosis and nervous and malignant affections.

Student Life in Japan.—The *Journal de Méd. de Paris* quotes a letter from Professor Revon, who taught for years at Tokio, in which he states that the distinguishing characteristic of Japanese students is that they study hard and are very eager to learn. When the lecture is over there is always a group appealing for further light on certain statements. After the professor has left the room the entire body of students gather round this bolder group and take notes of what they have learned. He adds: "During seven years of teaching in Japan, my only solicitude was the excessive amount of study done by some of my pupils. I tried in vain to curb their zeal; one of them became insane and several died. At the funeral of one of them, one of their mates advanced to the grave and exclaimed: 'Thou hast died from the sacred love of science; we will try to imitate thee!' A student a few years ago, by some undeserved mischance, failed to pass his examination. He came to bid farewell to his teachers, on the point of committing suicidal autolaparotomy. The faculty hastily assembled and made out his diploma at once. The young men study so hard that they grow prematurely old, with spectacles on nose, candidates for consumption. The medical course requires from thirteen to fourteen years of study before the final license to practice freely is obtained, instead of the five or six years required in western civilization. The relations between professors and pupils are peculiarly intimate and affectionate. From childhood the maxim is impressed on them: 'Your father and mother are like the earth and the sky; the ruler of the state is like the moon; your teacher, like the sun.' Another familiar proverb may be translated: 'Education surpasses birth,' that is, education is worth more than ancestral lineage and wealth."

Campaign Against Malaria in Italy.—In view of the sanitary efforts that will be necessary to contend with malaria in Panama, a special interest from an American standpoint attaches to the campaign that is being vigorously pushed against this disease in the Roman Campagna, a section once thickly peopled, the site of prosperous cities, but now, owing to malaria, a desert waste, not more than one-tenth of which is under cultivation. The public health reports state that the first inroads of malaria in the once flourishing Campagna were attributed to the neglect of the cultivation of land incident to changed social conditions brought about by the decline of the Roman Republic. In the past great efforts have been made, both by the papal and the Italian governments, to induce cultivation of this vast area, but owing to unfavorable economic conditions little has been heretofore accomplished. When malaria begins in May the section is practically deserted. The shepherds with their flocks take refuge in the mountains. With the discovery of the relation of mosquitos to malaria a rational prophylaxis became possible. At present the railroad employes, whose occupation renders it necessary for them to remain at their posts during the unhealthy season, are protected by screened houses, mosquito masks, and prophylactic administration of quinin. In the month of October, 1904, in the seven zones of the Roman Campagna, where the Italian Red Cross Society is making its anti-malarial campaign, prophylactic doses of quinin were given to 2,433 persons, in addition to those whose treatment was begun in previous months. In the zones under observation there were reported, during the month, 13 primary cases of malarial disease, 88 relapses, and 62 cases of non-malarial disease. Thirty-four patients were sent to Rome for treatment in hospital.

The Approaching International Medical Congress.—The fourth official bulletin has been received of the fifteenth International Medical Congress, to meet at Lisbon, April 19, 1906. It states that the number of official addresses assigned is 188 and that some of them have already been received. We note a number of American names among them: Novy of Ann Arbor, H. U. Williams of Buffalo, A. E. Macdonald of New York, A. E. Regensburger of San Francisco, A. Ravogli of Cincinnati, W. C. Gorgas and W. J. Morton of New York. The American committee of propaganda includes Frank Billings of Chicago, W. W. Keen of Philadelphia, F. Shattuck of Boston, A. Jacobi of New York, and Osler of Baltimore, with the President of the American Medical Association, Dr. J. H. Musser, as the chairman. The list of members who have sent in their subscriptions is also published. The congress medal is being engraved by the Paris physician-artist, Dr. Richer. An interesting souvenir of the congress is being prepared in the form of a medical guide to Lisbon and Portugal, with all the details, regulations and statistics that can possibly interest a physician and serve for reference later. The subjects of the various addresses are also given with the names of the speakers. Von Leyden of Berlin will present the present status of the cancer question; Balthazard of Paris, radioactivity and radiotherapy; Lassar of Berlin, inflammatory skin affections; Ravogli of Cincinnati, the precancer stage in relation to cutaneous cancer, and Hallopeau of Paris, what he calls quaternary syphilis; Vulpius of Heidelberg, spinal paralysis, and B. Fränkel of Berlin, cancer of the larynx. The committee of organization beg that communications for the congress may be sent in at the earliest possible date so that they can be published with care instead of being rushed through at the last moment. New subjects recommended are dangers of milk, nocturnal incontinence, hysteria and infantile neurasthenia, dentition and infections, school strain, hydrocephalus, congenital malignant tumors and their operability, general and local anesthesia for children, influence of tropical climates on descendants of northern colonists, mutual influence of vaccination and dermatoses, and secondary cataract.

LONDON LETTER.

A New Departure in the Teaching of Tropical Medicine.

The great advances in tropical medicine made so rapidly in the last few years in this country have from time to time been chronicled in THE JOURNAL. The importance which the subject has now attained is shown by a new departure in its teaching—the foundation of lectureships in protozoology and helminthology at the London School of Tropical Medicine. Protozoology has assumed in tropical medicine such great importance and such wide proportions that it is thought to demand the services of men specially equipped to keep pace with its advances. The same may be said, if not with so much force, of helminthology. Hitherto these subjects have been included in the general laboratory work taught in the schools of tropical medicine, but the subjects have outgrown general instruction and demand special teachers, special classes and special investigators. Thanks to the schools of tropical medicine, the physicians trained in the methods of investigating tropical disease and working in tropical countries now number many hundreds and by their labors a still further growth in our knowledge of protozoology and helminthology is to be expected in the next few years. It is thought necessary to have an authoritative center at which all observations may be focused and sifted, which will require what we do not now possess, well-trained experts. Zoologists of eminence are not wanting in this country, but for one to cope with the demands of modern tropical pathology he must specialize. The conditions of appointment to each chair are identical. The teachers must give their whole time to the service of the school and occupy themselves with research work and must teach for one hour a day in the aggregate, if required. Candidates holding medical qualifications will be preferred. The appointments will be for six years. The salaries will commence at $1,250 and rise by annual increments of $250 to $2,500.

Sulphur Dioxid as a Disinfectant and as a Destroyer of Rats.

An important report on investigations conducted for the medical department of the local government board by Dr. J. S. Haldane, F.R.S., and Dr. John Wade, D.Sc., into the destruction of rats and disinfection on shipboard has been issued. The bulk of the experiments were made with sulphur dioxid in the form of "Clayton gas," a special preparation for the disinfection of ships obtained by burning sulphur in the Clayton apparatus. Clayton gas mainly consists of the residual nitrogen of the air, a small amount of unconsumed oxygen, sulphurous acid gas in quantities up to 15 per cent., and a considerable amount of sulphuric acid in suspension. The experiments show that the gas under conditions easy to obtain forms a very efficient disinfectant of places to which it gains access. Pathogenic bacteria manifested different degrees of resistance. Anthrax spores were unaffected, but plague and cholera bacilli were destroyed after a few hours' exposure to an atmosphere of the gas containing 5 per cent. of sulphur dioxid. In disinfection the time of exposure was found to be more important than the degree of concentration of the gas. Rats were readily killed. Drs. Wade and Pembrey have shown that .5 per cent. of sulphur dioxid will kill rats within two hours. Cockroaches and fleas are also killed under these conditions. These results were readily obtained in comparatively empty spaces and in holds not containing cargo The results obtained in holds containing a ship's cargo were altogether different. The penetrating power of sulphur dioxid was found to be very gradual for many articles of the cargo, particularly woolen and other fabrics (not cotton) done up in tight bales. This was shown to be mainly due to the power of the fabrics to absorb the gas. Thus, a bale of wool absorbed at least ten times and a bale of jute at least four times its own volume. The absorption takes place in the outer layers; after many hours the air within the bale contains no sulphur dioxid. Similar absorptive power was shown by grain and other food substances. A further objection to the use of sulphur dioxid is its liability to damage articles exposed to it. In a hold packed with cargo not only did it fail to act as a germicide, but owing to the absorption by bales, it was insufficient to kill rats and insects. Drs. Haldane and Wade suggest that if it is desired to kill rats before discharging the cargo, a small proportion of carbon monoxid (say 10 per cent.) should be added to the gas used for the hold. The best results would be obtained by unloading the cargo, with precautions against the escape of rats, and then treating the empty holds with sulphur dioxid.

The Centenary of the Royal Medical and Chirurgical Society.

The greatest of the London medical societies, the Royal Medical and Chirurgical Society, was founded on May 22, 1805. The council has decided to celebrate the centenary in May next in a manner worthy of the occasion. There will be a reception at the society's rooms by the president, and an exhibition of books, prints, instruments, etc., published or in use at the time of the foundation of the society. A centenary volume will be published giving a narrative of the society and its work. There will be a festival dinner and a conversazione at the Royal College of Surgeons.

The New Director General of the Army Medical Service.

A new departure has been made by the appointment to the important post of director general of the army medical service of a comparatively junior officer. This is connected with the recent radical changes made in the service after the inquiry into the so-called "hospital scandals" of the South African War, and the appointment no doubt has the approval of, if it has not been inspired by, the advisory board of distinguished civil doctors which has recently been created. The new director general is Lieutenant-Colonel Alfred H. Keogh, an Irishman, who joined the service in 1880 and became lieutenant-colonel in 1890. He greatly distinguished himself as an organizer in the South African War, for which he received several decorations, and at headquarters, where he acted as a deputy to his predecessor.

New Expeditions of the Liverpool School of Tropical Medicine to West Africa.

On the occasion of the recent retirement of Sir William Macgregor (who is a medical man), from the post of governor of Lagos the Liverpool School of Tropical Medicine decided to mark their appreciation of his valuable services in the cause of health and sanitation in West Africa by sending further commissions to continue the investigations conducted there by the school for the past five years into tropical diseases. A fund was accordingly raised in honor of Sir William Macgregor at a farewell banquet given to him before his departure to Newfoundland, of which he has been appointed governor. The first expedition will be under the charge of Professor Boyce, the dean of the school. He will be accompanied by Dr. Arthur Evans, medical superintendent for one of the large Liverpool shipowners and by Dr. Clarke. The expedition will pay a short visit to the Gambia, French territory (Konakry), and Sierra Leone. A southern expedition will be in charge of Colonel Giles, late sanitary commissioner of the northwestern provinces of India, and Dr. R. E. MacConnell of McGill University. It will visit the Gold Coast, Lagos, Southern Nigeria and, if possible, Northern Nigeria. The principal object of the expedition will be to study the distribution of biting insects, to which in Africa a large proportion of the prevalent diseases are due, and to study the question of domestic antimalarial measures in the various colonies. At the present time, as announced in THE JOURNAL, the Liverpool school has an important expedition studying sleeping sickness in the interior of the Congo Free State, which has been there since August, 1903. Next year the school will send an expedition to the Amazon to study yellow fever, which is the second expedition it has sent for the purpose. Thus its enterprise is phenomenal, but the possibility of all these expeditions is largely due to the munificence of Sir Alfred Jones, president of the school, a wealthy Liverpool merchant who has contributed liberally. A deputation consisting of Sir Alfred Jones, Professor Boyce, Dr. Evans, Dr. Clarke, Colonel Giles, Dr. MacConnell of Canada, Dr. Thomas of Canada, and Dr. A. Breinl of Prague, waited on the colonial secretary for the purpose of securing his good wishes for the expeditions, which were readily given. The expenses of the expeditions have been entirely defrayed by subscriptions of Liverpool merchants.

DUBLIN LETTER.

A Workhouse Scandal.

A shocking state of affairs was brought to light recently in the North Dublin Union by one of the local government board's inspectors, Dr. Biggar. Into the nursery of that institution during the three years ended June 30, 1904, about 1,000 infants under 2 years of age were admitted, 396 of whom died, or two out of every five. An examination of the premises occupied gave an explanation of the mortality. These miserable children, of whom there are generally from 60 to 70 at a time, are packed into rooms insufficient for the number, ill-ventilated and foul smelling. The staff maintained to take charge of this nursery consists of one sister and two attendants (not nurses), with the assistance of six or eight inmates. The principal ward has practically no ventilation except by skylights, and the inspector states that the air therein had a very foul smell. It is stated, too, that the site of these dens which constitute the nursery was to begin with, unsuitable, since they are built on a disused graveyard. The children who are admitted to a union workhouse in this country are usually in anything but a healthy condition. Many are foundlings or illegitimate, and nearly all are suffering from the effects of poverty or of neglect. Many are actually ill. Such infants, instead of being herded together without either air or care, require, if they are to have any chance of healthy lives, strict medical attention and the best hygienic surroundings. Without the odium arising from the publicity of Dr. Biggar's report there is little reason to think that the North Dublin guardians would have paid any attention to the matter. After many postponements the guardians have at length adopted certain suggestions, which, though far from giving an adequate solution to the problem, will afford a temporary relief. As, however, the present winter is accompanied by much distress in Dublin, it is probable that the accommodation of the workhouse will be taxed to its utmost before the winter is over.

Richmond Asylum.

In view of the alarming increase of lunacy in Ireland, to which allusion was made in the last Dublin letter, the recent report of the Richmond District Asylum is particularly interesting. This asylum, the largest in this country, contains about 2,700 patients, and has for medical superintendent the well-known alienist, Dr. Conolly Norman. The number of patients under treatment continues year by year to increase, though the actual number of admissions last year was the same as in 1902. The cases admitted were mostly of an unfavorable nature as regards prospect of recovery, many of them being afflicted with what are regarded as incurable types of mental disease. Suicidal tendencies were more marked than usual, and several patients who feared suicide presented themselves as voluntary patients. Dr. Norman is a believer in a freer mode of treating the depressed than is usual in these countries, and he is to be congratulated that no successful attempt at suicide was made. It must, of course, be remembered that in no asylum in the United Kingdom is there so much freedom given to patients as is customary in America. Dr. Norman holds much the same views as Dr. Coulston of Edinburgh on the importance of alcohol in the causation of insanity, and we find that one-third of the cases where any cause has been assigned are credited to this cause. On the other hand, in the column headed "sexual intemperance" there is not a single entry. Hereditary influences were made accountable in 82 cases. The mortality of the asylum during the year was not unduly high, 7.9 per cent. of the average number of patients, but some of the causes seem to be capable of diminution. Phthisis especially is responsible for a larger number of deaths than should occur if modern preventive and therapeutic measures are practiced. It is interesting to note the variety and number of the industrial occupations in which it has been found possible to engage the great majority of the patients. All the clothes worn in the asylum have been made on the premises, and the stuff itself has been woven there. One can hardly think of any occupation from chimney-sweeping to "drawn-thread work," from blacksmith's work to embroidery, in which some of the patients are not employed.

Correspondence.

Modern Hospital Asepsis from an Interne's Viewpoint.

CHICAGO, Dec. 21, 1904.

To the Editor:—It seems almost superfluous and uncalled for to try to bring out anything more relative to asepsis in the modern hospital and operating room of to-day, but with the exception of a hint of them now and then to be seen in various articles in some of the later journals, no one has touched on two or three points that should be strongly emphasized and criticised, and the causes of which should be eliminated in order to get better aseptic surgical results.

One would think on close examination of one of the newer operating rooms that every precaution had been taken, that every means known to bacteriology had been or was constantly being employed to destroy the bacteria that had already gained entrance to the operative field and its environment and to prevent any further contamination. The room as a whole is built so that every square inch of its floor, walls and ceiling can be cleaned. There are no corners or ledges for dust or dirt to lodge or which are inaccessible to the frequently appearing scrubbing brush. Marble, iron, stone, tiling, enamel, glass and nickel are used exclusively in the make-up of the room and its necessary furnishings, not so much for the durability of such materials, but in order to obtain smooth surfaces which can be easily cleaned—surgically cleaned.

Everything that is brought into the room is surgically clean. The tables are scrubbed, washed with antiseptic solutions and covered with covers that have been sterilized. The basins, towels, sponges and instruments have all been baked, steamed or boiled. Only nurses specially trained in asepsis and antisepsis and in the reasons and necessity for the same, make the operating room ready for an operation and assist during it. In the dressing rooms are to be found scientifically arranged wash basins where hot and cold sterile water, sterile soap, sterile brushes and antiseptic solutions can be used without the necessity of touching anything that is not clean. Sterile gowns are put on, sterile gloves are at hand to cover the hands and sterile masks are ready to protect the open wound from the pathogenic bacteria that are present in such large numbers in our mouths and nostrils.

It certainly would seem improbable, yes, almost impossible, for clean wounds to become unclean in such an operating room, fitted with every appliance known to prevent it. But they do become unclean, wounds do become infected, clean hernias frequently must be "dressed" for days after the operation, single iridectomies do occasionally result in suppurating panophthalmias, ventral "suspensions" do become "fixations" after weeks of irrigation of purulent sinuses leading down to peri-uterine abscesses. Stitch abscesses do only too frequently occur. "Oosings" which are "only serum" do appear after interval, clean appendectomies. Redness and induration do occur even after the much abused poor, innocent catgut has been really and truly sterile.

And why?

It is not always due to some error in aseptic technic done behind the screen in the ward by the usually extremely careful nurse during the preparation of the patient, nor is it always due to the junior interne who, fresh from books on aseptics, is anxious to be known as a careful man in his preparation of the patient. It is not always because the bandage slipped up while the patient was being transported to the operating room from the bed. It is not always because the senior assistant interne has become careless because he is soon to leave the hospital. It is not always due to the fact that this or that unscrubbed nurse "touched things" about the sterile field. It is not always due to any peculiar affinity between bacteria and catgut, and it is not always because the "fool patient stuck his finger under the eye-pad to stop the itching."

But such unnecessary and inexcusable infections do occur and often, too, in our best hospitals and in our most carefully managed operating rooms. It seems to me that the real cause lies not with the hospital operating room, internes or nurse, but with the surgeon himself, the operator, the teacher and professor of aseptic surgery, and simply because he does not really do what he teaches others to do, what he believes should be done, and what he doubtless for the most part thinks he does do.

He says to the class, "Scrub hard for fifteen or twenty minutes," and then he comes hurriedly to the clinic and scrubs but two or three, in spite of the fact that he knows very well that he can not put on sterile gloves with unclean hands. He says, "To obtain aseptic surgical results you must not only make clean, but you must keep clean," and within a few moments he has literally removed his glasses with his sterile glove, or has traced a drawing on a blackboard and then, with not so much as a dip into the bichlorid solution, takes up the iridectomy knife to remove the cataract.

He says to the assistant. "While you are in my service do not go to the autopsy room," and yet he will come directly to an operation from the dissecting room himself.

Teachers of surgery—leading clinicians of to-day—can be seen daily grossly breaking the fundamental rules of asepsis in all our leading clinics and hospitals. They are very exacting about others and then very careless about their own behavior. The first is excellent, the last is unpardonable. The more strict with nurse and interne they are the better, but they must not expect the nurse and interne to remain enthusiastic about absolute surgical cleanliness when they see him—just because he is late or in a hurry, or for no reason whatever—neglect to do what he demands of them.

It is not necessary to go more into detail. Scores of such instances of aseptic lying are noticed by an interne during his year or two of service relative to some of our best operators. The same operator should know he is constantly watched, looked up to, listened to and gladly followed just so far as he is true to surgery and to himself, and criticised and ridiculed just so far as he blames nurse, interne or catgut when it is only too evident that he himself has been the cause for failure of primary union. JOHN C. HOLLISTER.

Urination in the Dorsal Position.

LANCASTER, PA., Jan. 3, 1905.

To the Editor:—The inability to void urine lying down is common to many people even in health. By practice this may be overcome; rather easily when the half reclining position may be assumed, and the ability to urinate in the dorsal position gradually acquired. The patient usually has the joy of learning the technic of dorsal urination with added zest from postoperative pain and ether nausea.

I have found it of distinct advantage to have all patients who will have to void in the dorsal position practice this often before the position is necessitated, when time permits. In obstetric cases I order the morning urination on the douche pan during the last month of pregnancy until the knack is thoroughly acquired. In operative cases advantage is taken of every opportunity during preparatory treatment. I have had no patient who learned to void before operation who could not void afterward, excluding, of course, obstetric cases in which there had been much pressure on the urethra, and operative cases involving the region of the urethra or rectum.

Where the physician is so situated that he must either catheterize the patient himself or must trust to untrained assistants any help to make a patient void is of great value. Under the best surroundings there is danger in catheterizing. Patients readily see the value of this practice and are glad to adopt it. I have found that the procedure saved me a very great deal of trouble. JOHN L. ATLEE.

Sarcoma of Intestines.

RIVERSIDE, CAL., Dec. 30, 1904.

To the Editor:—Five years ago I removed from Harold S. a small round-celled sarcoma with several inches of intestine, from which it originated. The case was reported

Journal, March 9, 1901, under the title "Sarcoma of the Intestines with Table of Fifteen Cases of Resection." A few weeks ago I visited this patient, now as well developed and as robust a boy of 10 as one often sees. I found no evidence of trouble about his abdomen or lymphatics, nor anywhere, in fact. The only effect traceable to the operation was a little more frequency of bowel movements than normal, but this never amounted to a diarrhea; usually there were one or two movements a day. In view of the fact that although a number of enlarged mesenteric glands were of necessity left in the abdomen and that there was no return of the growth some very interesting questions are suggested. Were the glands that were left in the mesentery real sarcomatous foci? Has the organism a certain amount of power to overcome a sarcomatous "infection"? Is there a benign growth which so nearly resembles sarcoma that experts fail to distinguish it?

C. Van Zwalenburg, M.D.

Queries and Minor Notes.

Anonymous Communications will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

ERRORS IN VON BERGMANN'S SYSTEM OF SURGERY.

Winfield, Ark., Dec. 31, 1904.

To the Editor:—On page 17, vol. iv, of von Bergmann's System of Surgery, by Bull, I notice what might be construed a great mistake. On lines 10 and 11 it is said to use a tube 10-15 cm. Does it mean ten-fifteenths or ten and fifteen one-hundredths cm.? On the same page the bifurcation of the esophagus is spoken of. Chevis Bevill.

Answer.—It is very evident that the "10-15 cm." on page 17 of vol. iv of "Von Bergmann's System of Surgery" by Bull, is a mistake, as it should be "10-15 mm." The term "bifurcation" on the same page refers not to a bifurcation of the esophagus, but to the bifurcation of the trachea. The word trachea might have been inserted to advantage and the sentence would have been relieved of all ambiguity.

SERUM TREATMENT OF CANCER.

Gulfport, Miss., Dec. 18, 1904.

To the Editor:—Have there been any favorable developments in experiments on serum treatment of inoperable cancer of the uterus? If so, please give me any information available as to where or how I may obtain the serum. R. C.

Answer.—There is at present no recognized serum treatment of cancer. Doyen of Paris, France, claims to have a serum which he is using in the treatment of inoperable cancer, and has recently obtained considerable newspaper notoriety concerning it. Metchnikoff has recently reported on the matter in the French medical press. The serum is obtained from the *Micrococcus neoformans*, which is supposed by them to be the cause of cancer. It has not yet been established either that the organism mentioned is the cause of cancer or that the serum possesses any curative properties. The serum is not obtainable here, so far as we know. See also page 145.

Marriages.

William G. List, M.D., Cincinnati, to Miss Martha White, December 20.

Julius Propper, M.D., to Miss Gizelle Propper, both of Philadelphia, December 29.

William Pepper, M.D., to Miss Mary Godfrey, both of Philadelphia, December 31.

Edwin D. S. Mullison, M.D., Philadelphia, to Miss Fannie W. Warren of Wrightstown, N. J., December 31.

George Johnson Tompkins, M.D., to Miss Elizabeth Haskins Dillard, both of Lynchburg, Va., December 28.

Walter L. Bond, M.D., West Somerville, Mass., to Miss Bertha B. Fennell of Everett, Mass., Nov. 2, 1904.

Talbert B. Ginn, M.D., Hesselton, Ky., to Miss Mattie Hillis of Vanceburg, Ky., in Cincinnati, December 16.

Deaths.

Byron Cook Pennington, M.D. Jefferson Medical College, Philadelphia, 1881, fourth vice-president of the American Medical Association; president of the medical staff of, and surgeon to the Atlantic City Hospital; president of the Atlantic City Academy of Medicine; several times president of the Atlantic County Medical Society; for two years and a half surgeon in the merchant service between New York and Brazil; a member of the Atlantic City council, died at his home in Atlantic City, N. J., January 1, from uremia, after a long illness from interstitial nephritis, aged 46. In recognition of the personal and professional integrity and ability of Dr. Pennington the physicians of Atlantic City united last October in presenting to him a silver loving cup. He was chairman of the general committee of arrangements for the American Medical Association session of 1904.

Eber K. Watts, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1879, a member of the American Medical Association and of the Wayne County (Ind.) Medical Society, some-time coroner of Wayne County, for 18 years a practitioner of Richmond, Ind., died suddenly while attending a consultation near Westville, Ohio, January 3, from uremia, aged 45.

Arthur C. Adams, M.D. Medical Department of Columbian University, Washington, D. C., 1873, a member of the American Medical Association, shot himself at his home in Washington, December 31, and died at Providence Hospital early on January 1, aged 50.

Robert H. Somers, M.D. Toronto University Medical Faculty, 1896, a member of the American Medical Association, one of the most popular physicians of Plymouth County, Iowa, died at his home in Lemars, January 3, after an illness of one week from pneumonia.

Hiram W. Young, M.D. Medical Department of Washington University, St. Louis, 1901, of St. Louis, was drowned by the upsetting of a gasoline launch in which he was making a cruise to Florida, about 25 miles below St. Louis, December 30, aged 33.

Calvin H. Kendall, M.D. Berkshire Medical College, Pittsfield, Mass., 1843, one of the first to employ nitrous oxid gas as an anesthetic in the extraction of teeth, died at his home in Ridgefield, Conn., Nov. 30, 1904, from uremia, aged 87.

Arthur T. O'Hara, M.D. University of Buffalo Medical Department, 1890, for 13 years physician and superintendent of the Buffalo Quarantine Hospital, was found dead in that institution January 1, from heart disease, aged 43.

Joseph Bartley Patrick, M.D. Medical Department of Western Reserve University, Cleveland, 1886, of Baldwin, Wis., died in St. Luke's Hospital, St. Paul, Minn., December 30, from post-operative pneumonia, aged 48.

Frederick H. Griffin, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1880, committed suicide at his home in Philadelphia, January 1, by inhaling illuminating gas, aged 48.

Shorland Harris, M.D. Exeter College, England, 1852, a surgeon in the Crimean War, died at his home in Mason City, Iowa, January 1, from cerebral hemorrhage, after a short illness, aged 75.

Evan F. Smith, M.D. Medical Department of the Columbian University, Washington, D. C., 1878, died at his home in Brooklyn, N. Y., from influenza, after a short illness, January 3, aged 53.

Joseph L. Richard, M.D. Tulane University of Louisiana Medical Department, New Orleans, 1870, died at his home in Donaldsonville, La., December 31, after a short illness, aged 56.

John G. Lee, M.D. University of Louisville Medical Department, 1865, died at his home near Lasca, Tenn., December 24, from paralysis after an invalidism of eight years, aged 75.

Emory F. Gresham, M.D. Hospital College of Medicine, Louisville, 1892, died at his home in Sedalia, Mo., December 28, from brain tumor after an illness of several weeks, aged 35.

Amos C. Wood, M.D. New York University, New York City, 1855, the oldest practitioner of Owensboro, Ky., died at his home in that city, January 2, from heart disease, aged 80.

Gustavus A. Rene, M.D. Medical College of the Pacific, San Francisco, 1872, of San Bernardino, Cal., died at the hospital in that city, December 23, after a long illness, aged 63.

James E. Jones, M.D. Albany (N. Y.) Medical College, 1855, for 45 years a resident of Clayville, N. Y., died at his home near that village, December 25, aged 72.

James M. Eagleton, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, died at Ocala, Fla., January 4, from heart disease, aged 70.

Harry Lewis Hamilton, M.D. California, 1891, died at his home in Chicago, Cal., December 30, from spinal meningitis, after an illness of 36 hours, aged 33.

Frank E. Yerkes, M.D. Pennsylvania, 1894, died at his home in Ambler, Pa., December 16, after an illness of four days, from erysipelas, aged 38.

Hector S. Aley, M.D. Rush Medical College, Chicago, 1885, died at his home in Denver, Colo., December 9, from pernicious anemia.

David M. Shively, M.D. Indiana State Board, 1897, died at his home in Yorktown, Ind., from nephritis, January 3, aged 63.

Thomas A. Pierce, M.D. Philadelphia, 1850, died recently at his home in Winona, Minn., and was buried January 7.

Book Notices.

ELECTRO-DIAGNOSIS AND ELECTRO-THERAPEUTICS. A Guide for Practitioners and Students. By Dr. Toby Cohn, Nerve Specialist, Berlin. Translated from the Second German Edition and Edited by Francis A. Scratchley, M.D., New York, Chief of Clinic, Diseases of the Nervous System and Instructor in Electro-Diagnosis and Electro-Therapeutics, University and Bellevue Hospital Medical College. With Eight Plates and Thirty-nine Illustrations. Cloth. Pp. 250. Price, $2.00. New York and London: Funk & Wagnalls Co. 1904.

This book presents the underlying scientific principles of electrodiagnosis and electrotherapeutics. It also explains the apparatus necessary for the use of electricity in the disorders where it is indicated. The book is conservative in spirit and has reached a recognized standing in Germany.

A TREATISE ON APPLIED ANATOMY. By Edward H. Taylor, M.D. (Dublin Univ.), F.R.C.S.I., Surgeon to Sir Patrick Dun's Hospital. Illustrated with 178 Figures and Plates from Original Drawings, Many Printed in Colors. Cloth. Pp. 738. Price, $9.00. London: Charles Griffin & Co. Philadelphia: J. B. Lippincott Co. 1904.

The author's "object has been to provide an account of the regional anatomy of the human body in its more important applications to medicine and surgery." This has been so well done that nearly every point in anatomy has been intimately connected with some practical point in medicine or surgery so that the reading of the work has been made not only instructive but a pleasure. The work contains almost as much surgery as anatomy, and the illustrations, many of which are colored, are all very good. It is a good work and one which can be consulted with profit not only by the student but by the operating surgeon.

NEW METHODS OF TREATMENT. By Dr. Laumonier. Translated and Edited from the Second Revised and Enlarged French Edition by H. W. Syers, M.A., M.D., Cantab., Physician to Out-patients Great Northern Central Hospital. Cloth. Pp. 320. Price, $2.50 net. Chicago: W. T. Keener & Co. 1904.

This book is of peculiar importance in that it takes up and discusses the relative value of the more important newer remedies of the vast number which have been placed on the market. As a rule, the general practitioner gains his acquaintance with these newer remedies only in published formulas and prescriptions which in many instances gain their entrance into medical literature through the advertising columns. The author divides the several preparations into groups according to their actions and uses, including in this classification nutritive alterants, blood alterants, mineral medication, respiratory alterants, renal alterants, vasomotor alterants, opotherapy, serotherapy, nerve alterants, antipyretics and antiseptics. Space can not be given to the discussion of these different groups. To the physician who wishes a more thorough comprehension of the relative value of the newer preparations than can be obtained in the current literature, this book can be safely recommended.

THE PATHOLOGY OF THE EYE. By J. Herbert Parsons, B.S., D.Sc. (Lon.), F.R.C.S. (Eng.), Assistant Ophthalmic Surgeon, University College Hospital. Vol. I. Histology—Part I. Cloth. Pp. 388. Price, $3.50 net. New York: G. P. Putnam's Sons. 1904.

This is the most complete work of its kind ever undertaken in any language. Even in Germany the "Ginsberg Manual" is the only book which may be said to compare with Mr. Parsons' work. The first volume by its excellence promises much for those that are to follow. The work presents more than its title indicates; it abounds in practical applications of pathology to the surgery and treatment of eye diseases. In discussing a given condition, in addition to its pathology and histology Mr. Parsons has collected the theories and opinions of the world's authorities and has most successfully welded them into a very practical, homogeneous whole. Many of the more valuable of the late methods of laboratory technic are also given. The illustrations are taken chiefly from photographs, another good point, since the advanced student no longer needs schematic drawings, but prefers to see things as they really are to be seen under the microscope. There might, with advantage, be many more illustrations, and especially those in color, none of the latter appearing in the first volume. The binding also is inferior, especially for a work which is of such value that it can not fail to be in constant use.

PRACTICAL MEDICINE SERIES OF YEAR BOOKS, Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Issued Monthly. Under the General Editorial Charge of Gustavus P. Head, M.D., Professor of Laryngology and Rhinology, Chicago Post-graduate Medical School. Vol. VIII. Materia Medica and Therapeutics, Preventive Medicine, Climatology, Suggestive Therapeutics, Forensic Medicine. Edited by George F. Butler, Ph.G., M.D., Henry B. Favill, A.B., M.D., Norman Bridge, A.M., M.D., Daniel R. Brower, M.D., Harold N. Moyer, M.D., July, 1904. Volume IX. Physiology, Pathology, Bacteriology, Anatomy, Dictionary. Edited by W. A. Evans, M.S., M.D., Adolph Gehrmann, M.D., William Healy, A.B., M.D., August, 1904. Vol. X. Skin and Venereal Diseases, Nervous and Mental Diseases. Edited by W. L. Baum, M.D., Hugh T. Patrick, M.D. September, 1904. Chicago: The Year Book Publishers.

Volume VIII keeps up the standard that has been maintained by this valuable series. Butler's review of materia medica and therapeutics is especially full, occupying nearly one-half of the volume, and seems to give a very complete résumé of the advances that have been made during the year covered. Favill's review of Preventive Medicine is also judicious and thorough, and the same may be said of the section on climatology by Bridge and Claypole, and those on suggestive and forensic medicine, respectively, by Brower and Moyer. The editors have given us well-selected abstracts and the excerpt affording a fair résumé of the general advances made during the year. Volume IX covers much ground, but the material has been well selected, thus making one of the most valuable books of the series. W. A. Evans reviews anatomy and pathology, including general and special pathology. A. Gehrmann has charge of the section on physiology and bacteriology, considerable space being devoted to biochemistry and serum reaction, and Wm. Healy has compiled the dictionary of new words, which embraces twenty-two pages of nonpareil type. Volume X covers only two subjects, cutaneous and venereal diseases, by W. L. Baum, including genitourinary medicine and surgery, and nervous diseases by Patrick and Mix. Both are able and comprehensive critical reviews of the advances made during 1903 and cover a considerable portion of the literature of their respective subjects. The portion on mental diseases is rather brief, but the papers abstracted are well selected and the critical remarks of the editor are valuable as conveying judicious opinions on certain special points.

SURGICAL EMERGENCIES. THE SURGERY OF THE ABDOMEN. Part I. Appendicitis and Other Diseases. About the Appendix. By Bayard Holmes, B.S., M.D., Professor of Surgery in the University of Illinois. Paper. Pp. 349. Price, $2.00 net. New York: D. Appleton & Co. 1904.

The author states that his volume of 350 pages is a part of "A Text-Book of Surgery for Practitioners of Medicine." As a text-book article, there is much in it that could be eliminated and much that could be condensed with advantage, particularly on the subject of appendicitis, for the complete title of the work is "Appendicitis and Other Diseases About the Appendix." With some of the author's statements we can not agree; for instance, "The examination of the patient forms only a small part of the material on which the diagnosis (of appendicitis) is made." On the contrary, the physical examination of the patient plays a very large and important part in the diagnosis in a large proportion of the cases. The statement that "The appendages of the intestinal tract, especially the appendix vermiformis, the gall-bladder, and Meckel's diverticulum are traps laid for the purpose of catching and disseminating infection," might pass in a figurative sense, but when unqualified, as it is here, is not good in a text-book. The formula given for Schleich's solution on page 209 is incorrect, as it contains too much morphin, and Schleich does not use "normal salt solution." The statement on page 241 that "Ideal appendicectomy ought not to require an incision longer than an inch in the thin and an inch and a half in the fat patient; it ought not to require more than fifteen minutes of general anesthesia nor more than four or five days in the hospital and away from work or business" is pernicious in more ways than one. The incision should be long enough to permit the necessary work to be properly done regardless of the tape measure. Good work in many cases cannot be done through an inch incision. No patient who has had the abdomen opened and work done on the intestine should be permitted to leave the hospital and to resume his work or business in four or five days. The process of repair requires time and until repair is reasonably complete accidents may happen, and a surgeon is not justified, under ordinary circumstances, in permitting his patients to take the risk of returning to work. The author's views concerning the desirability of early operation and the very earnest and forceful manner in which he presents his arguments therefor are commendable. The "other diseases about the appendix" treated are peritonitis, intussusception, perforating typhoid ulcer and carcinoma of the intestinal tract. These are not so extensively dealt with as is appendicitis. Although one will find a number of statements to which one can not subscribe, still the work as a whole forms an interesting and instructive monograph, written in a very positive style.

THE ACTION OF LIGHT AS A THERAPEUTIC AGENT. By Leonard K. Hirshberg, Baltimore, Md. Fiske Fund Prize Dissertation. Cloth. Pp. 49. Providence: Snow & Farnham. 1904.

ROENTGEN-RAY DIAGNOSIS AND THERAPY. By Carl Beck, M.D., Professor of Surgery in the New York Postgraduate Medical School and Hospital. With 322 Illustrations in the text. Cloth. Pp. 460. Price, $4.00. New York and London: D. Appleton & Co. 1904.

LIGHT ENERGY; Its Physics, Physiological Action and Therapeutic Applications. By Margaret A. Cleaves, M D, Fellow of the New York Academy of Medicine. With Numerous Illustrations in the Text and a Frontispiece in Colors. Cloth. Pp. 827. Price, $5 00 net. New York and London: Rebman Co 1904.

The number of books dealing with the various forms of radiant energy and their application to medicine is increasing rapidly. One of the first books in this field which has proved so productive of literary activity was that of General Pleasanton on "The Influence of the Blue Ray of the Sunlight and of the Blue Color of the Sky in Developing Animal and Vegetable Life in Arresting Disease and in Restoring Health in Acute and Chronic Disorders to Human and Domestic Animals," published in Philadelphia, 1877. The general's book was printed with blue ink and bound in blue. This led Finsen to suggest that "its contents could hardly fail to be colored also," a remark not without reason in view of General Pleasanton's tendency to regard blue light as a panacea. Of the three books at present noticed, the first may be dismissed with the statement that it was deemed worthy of the Fiske prize. It contains nothing particularly new. Dr. Beck's book on the Roentgen ray is marred by the introduction of *many* unnecessary details especially concerning individual cases. Numerous and often poorly made illustrations have been inserted; those of microscopic sections are wholly worthless. There is a tendency, it would seem, to stretch the efficacy of the *x*-ray to the utmost, as noticed for instance, in the following statement in speaking of one case of scarlatinal noma: "It seemed that after strong irradiation the process was checked." On the whole, no very serious attempt is made at careful, critical analysis of the diagnostic and therapeutic value of the *x*-ray on the basis either of the author's own material or that of others. The book is consequently not stimulating in its tone, although, of course, it contains much valuable information. Dr. Margaret A. Cleaves presents a more comprehensive work of its kind, in which she endeavors to embody the results of eleven years of study and practical experience. She does not consider fully the *x*-ray except more or less incidentally. The fundamental physics are considered at length. Dr. Cleaves has chosen as her aim the placing of light energy for general therapeutic purposes on a foundation as secure and scientific as that which the brave Finsen provided for its use in diseases of the skin. This is an ambitious undertaking, but the author has proceeded in the only way that leads on to its successful realization, namely, by critical study of all available material before drawing any conclusions. We believe this book may be recommended to those who wish to have on hand an able and conscientious discussion of light in its physical, physiologic and therapeutic aspects.

Miscellany.

GREAT INACCURACIES IN THE DOSAGE OF POTASSIUM IODID IN SATURATED SOLUTION.

Dr. William Healy.

CHICAGO.

Discussion between a druggist and a patient who thought he was not getting his regular amount of potassium iodid in solution led me to note an inaccuracy in the usual making up of the saturated solution. Later, in conversation, Dr. H. T. Patrick called my attention to a still greater error; namely, that most physicians regulate the dosage of this frequently prescribed solution as if one drop of the solution equaled one grain of the drug. I had always done so on the authority of Hare (Practical Therapeutics, ed. 1897, p. 225). This is far from being the truth. In proving up this matter on a practical basis, as I have done in company with two expert pharmacists, I note even a third possibility of error in dosage—the content of the domestic teaspoon.

The standard pharmacopeial authorities state that potassium iodid is soluble in .75 parts water, standard temperature C. 15, F. 59. I find that on this authority it is common for druggists to simply add these properties in making the saturated solution. Now waiving the point as to possible difference of solubility varying with different methods of manufacture, and working with granulated potassium iodid, such as druggists ordinarily carry, I find that potassium iodid ʒiv added to distilled water ʒiii gives a mixture of ʒivss. This, however, at room temperature, F. 70, is not a saturated solution. Almost another dram of potassium iodid can be dissolved, bringing the mixture then up to ʒiv, m. i, practically one grain to the minim.

Now with regard to drops: I find them, as Dr. Patrick asserted, very small, indeed. Since it is almost impossible to drop the solution over the neck of a bottle, a medicine dropper is ordered. *Using the common straight dropper 60 drops* is found to equal only from 28 to 40 minims. From an eye pipette sold at some places as a medicine dropper 60 drops equals from 46 to 49 *minims. Sixty drops from a thin glass* beaker equals 28 minims and from a small graduate equals 39 minims.

Then, investigating the household measures, I find that what the laity considers a teaspoonful of the solution in question contains from 85 to 95 minims. How ludicrously inaccurate these various methods of dosage are is shown by their comparison. For instance, if one prescribes the 60 pipette drops fondly supposed to be a dram of the so-called saturated solution he is giving only about 41 grains of potassium iodid, or if he orders a teaspoonful, also thought of as a dram, he may be giving 90 grains—over twice as much. Or putting it in another way, the teaspoonful contains about 120 pipette drops.

Summarizing these various difficulties it appears, then, that when using the thoroughly saturated solution, *dropped from a* pipette, there is an error of at best 25 per cent. and when given by the teaspoonful of 33 per cent. Or, if properly measured by minims, the druggist's mixture *may involve a difference of* 12 per cent. In giving the large doses over the prolonged periods, which so frequently has to be done, it would be distinctly worth *while to know what we are doing.* As *it stands*, with most of us, when we think we are giving, say, 120 grains we may really be giving 110 grains or 90 grains, or ,160 grains. Evidently the only way to be even approximately accurate is to prescribe potassium iodid in solution *completely* saturated and measured for dosage, as it may be more rapidly and conveniently than by the pipette in a minim graduate.

1682 Sheridan Road.

Expert evidence is not evidence of fact, it is evidence of opinion based on scientific knowledge. Medical men give evidence of fact when they speak in the witness-box as to physical conditions which have come under their actual observation; but when they draw inferences from those conditions as to the duration of injuries, as to the amount of incapacity produced, or as to the cause of them so far as these points lie outside the limits of their knowledge, they then become expert witnesses.—*Lancet.*

Alcohol and Hypnotism.—Russian physicians are treating alcoholic cases by hypnotism, according to the *Gazette Médicale de Paris*. The first dispensaries for the treatment of alcoholism by hypnotism were used in 1896 in the psychiatric clinic of Moscow, and in 1891 at the hospital of Ijevo. Since then many establishments of the same kind have been started at Ekaterinislav, Voronege, etc., and all have given excellent results. According to the studies of Dr. Rybazoff the treatment of alcoholic cases by hypnotism has given 75 per cent. of radical cures, while all the other known methods have never given more than 30 per cent.

Doyen's Cancer Serum.—According to the *Semaine Médicale*, Doyen formally reports that Metchnikoff has obtained pure cultures of the *Micrococcus neoformans* in 41 out of 121 tubes inoculated with cancer material. The colonies were most numerous in material from the more malignant tumors. Doyen claims that 15 patients with cancer, inoperable in October, have been so much improved by his serum treatment that surgical intervention was rendered possible, and was successfully done. Two cancers of the breast, he claims, subsided completely under the treatment, which allowed the removal of an advanced tumor on the other breast. Before the Paris Société de Chirurgie, December 14, Doyen exhibited these and 8 other patients with advanced cancers whom he proposes to treat with his serum and to operate on later.

Consanguinity in Genesis of Deafness.—M. Natier of Paris has recently reported 2 cases of deafness coming on in the twenties in two sisters, whose parents had been cousins. The deafness is bilateral, progressive and accompanied by subjective symptoms, and has proved rebellious to all treatment. He has been very successful in other cases of deafness—sometimes in cases incurable by all other means—by re-educating the ear with acoustic exercises with tuning forks. He calls this the physiologic re-education of the ear, and states that if used early in encroaching deafness, it will ward it off. The general health must be kept in good order at the same time. His communication on the subject was read at the recent French Congress of Internal Medicine, and is published in the *Gazette Méd. de Paris*, November 5.

Hydrophobia in Berlin.—The German authorities have published a report of those in Berlin bitten by suspected mad dogs during 1903. During the year 307 persons were bitten by dogs supposedly mad. Rabies was conclusively demonstrated in 140 of the dogs. Of the 307 persons bitten, 281 (or 1.5 per cent.) received the Pasteur treatment. Of these only 4 succumbed, and one is reported to have recovered after the appearance of the symptoms of the disease. Of those not treated by the Pasteur method, but receiving other medical treatment, 6 per cent. died of the disease, and of those receiving no treatment whatever, 11 per cent. Allowing for the fact that a large proportion of patients bitten by supposedly rabid dogs do not develop the disease, the fact that four times as many recover after the Pasteur treatment as after other medical treatment, and nine times as many as after no treatment at all, is worth considering. Hydrophobia is probably the most terrible acute disease known to man. Fortunately, it is rare. Once well developed, it is practically incurable, though the one case reported in the Berlin statistics as recovering encourages a slight hope that even more may be done in the future.

The Bone Marrow as a Protecting Organ Against Infections.—The participation of the bone marrow in the defense of the organism against infections is well shown by the appearance of myelocytes in the blood when an infection is installed. Their presence or absence is an important element for the prognosis in pneumonia, for instance. Hoke of Prague has been studying this subject on animals, and reports his research in the *Zeitschrift f. Heilkunde*, xxv, No. 8. He considers it highly probable that macroscopic changes occur in the bone marrow likewise. Among his experiments were some in which he incorporated bone marrow in certain organs, simulating natural chemotactic processes, attempting in this way to demonstrate some direct action on the part of the bone marrow. His experiments are interesting, although not conclusive to date.

Praise for a Physician.—Some physicians and some medical publications occasionally have something to say about the lack of appreciation, among the laity, of the real worth of physicians. It is well to note such a tribute as the following, from the *New York Times:*

> When Dr. Carlos Finlay talks about health conditions in Cuba he must be heard with as much confidence as respect, for to special knowledge acquired by many years residence in the island he adds a thorough familiarity with all the new information in regard to the relations between insects and fevers, and he has a peculiar reason for believing in the reality of that relation and acting in accordance with it. For he is the man who, years and years before more than one or two people, if any, had begun to look with suspicion on the mosquito as a possible carrier of disease, positively and publicly charged the creature with performing that ill-service in the case of yellow fever. This conclusion he seems to have reached by a sort of divination, for his facilities were not such as to permit him to prove his theory, and it was so novel, so contrary to all the accepted ideas as to the conveyance of the so-called malarial maladies, that his now famous paper attracted no attention at all except a few pitying smiles, and it was left for our own Army surgeons, as part of the army of occupation in Cuba after the war with Spain, to take up the matter in the light of discoveries made in India and Italy, and turn Dr. Finlay's unsupported assertion into an absolute demonstration. This gave him the best of rights to say, "I told you so," but he has done it as little as could be expected from a mere mortal, and has taken no pains at all either to win fame for himself as a discoverer or to diminish that of investigators who, however admirable their work, could not have claimed his complete originality.

Clippings from Lay Exchanges.—"To the medical reader," remarks the *British Medical Journal*, "there is often more excellent fooling in the daily newspapers than in the professedly comic journals. The fun is unintentional, of course, but that makes it all the better, for, as Mr. Barrie's humorist says, two persons are required for the prosperity of a jest—one to make it and the other to see it. On the death of Professor Finsen, a message from Copenhagen informed the world that the initiator of the light treatment had died of 'calcination of the pericardium.' Not long ago the *St. James' Gazette* gave Lord Lister the credit of having devised the method of 'healing by first intention,' a soft impeachment which, we are sure, the great surgeon would be unwilling to own. Another evening paper is responsible for the statement that 'hemophilia, or lust of blood, is a well-known sign of degeneration.' In the matter of comic medicine the British press must, however, yield the palm to American journalism." There are then quoted some of the humorous bits with which THE JOURNAL readers have been made familiar through our column entitled "Clippings from Lay Exchanges."

Tuberculosis and Soiled Linen.—S. Bernheim of Paris, in a communication to the recent French Congress of Internal Medicine, expatiated on the danger of contagion from the soiled linen of consumptives. The soiled clothing of the family is usually kept in permeable receptacles, and when sorted out to send to the laundry becomes a menace if any member of the family is tuberculous. The bundles are piled with those from other families, and the employes in the laundries are liable also to become infected. In fact, the employes in laundries supply the largest contingent to the clientèle of the antituberculosis dispensaries throughout the country. He advocates that soiled linen should be kept in airtight receptacles and sent to the laundry in impermeable bags, disinfected at once on arrival. A still better measure would be to have a central city laundry where the linen from consumptives being treated at the special dispensaries should be laundered free, or at minimal rates. These simple measures would prevent many cases of new infection.

A Pure-Food Law.—In a paper by Dr. E. J. Lederle read at the International Congress of Arts and Science at St. Louis, attention was called to the fact that competition in trade has become so keen and the substitution of inferior constituents in foods so general that the honest manufacturer has hardly a chance to succeed. The paper also stated that the use of injurious preservatives is practiced to a scandalous extent, and that the only remedy for these conditions is the passage and enforcement of a federal pure-food law. The paper went on to state that the public in general does not understand the extent to which patent medicines and secret nostrums undermine the public health, and says that there has been little or no attempt made to assume official control over their production and sale. Dr. Lederle considers that makers of patent medicines should be required to place on each package or bottle the exact ingredients it contains, and should be prosecuted for any deviation which can be shown to be detrimental to the health of the persons using the remedy, or which is designed to perpetrate on them a commercial fraud.

Responsibility of Authors for Their Formulas.—The Lyons courts recently acquitted a physician who had made an injection of 40 gm. of a 5 per cent. solution of cocain with the consequent death of his patient. The operation was for the relief of hydrocele, and the patient succumbed in twenty minutes after the preliminary injection of the cocain. The physician stated that he had merely followed the directions in Tillaux' Manual of Clinical Surgery, second edition, page 411, which advised for such cases an injection of "about 30 grams of a 5 per cent. solution of cocain;" that is, a gram and a half of cocain. In the third edition, which followed three years later, Tillaux warned against large doses and advised "about 10 grams of a 1 per cent. solution," that is, 10 cgm. The necropsy revealed pleural adhesions which made any injection of cocain dangerous. The court acquitted the physician, stating that the citation from Tillaux' text-book freed him from responsibility. Professor Tillaux was president of the Paris Académie de Médecine at the time of his death last fall, which occurred not long after this legal decision. The *Journal de Méd. de Paris*, commenting on the affair, remarks that the decision evidently offers a precedent for holding the author of a book or formula responsible if the application of his formula entails any mishap. It doubts, however, if this precedent will be accepted in jurisprudence, as any physician making such an injection ought to know enough not to inject 2 gm. of cocain under any circumstances. "Our confidence in the works of the masters should not deprive us of our powers of judgment." A similar case was recently decided in Georgia. The proprietor of a patent medicine was sued for injuries by a person who had taken the medicine. The court held that the proprietor was responsible and stated that after careful search not only in the authorities quoted by counsel, but in others, no record of a similar question having been determined by any court could be found. The court held further: "If the contents of a medicine are concealed from the public generally, and the medicine is prepared by one who knows its contents, and he sells the same, recommending it for certain diseases and prescribing the mode in which it shall be taken, and injury is thereby sustained by the person taking the same, proprietor would be liable for the damage thus sustained. . . . These proprietary or patent medicines are secret, or intended by the proprietors to be secret, as to their contents. They expect to derive a profit from such secrecy. They are, therefore, liable for all injuries sustained by any one who takes their medicine in such quantities as may be prescribed by them. . . . He has a right to rely on the statement and recommendation of the proprietor, printed and published to the world; and if, thus relying, he takes the medicine and is injured on account of some concealed drug of which he is unaware, the proprietor is not free from fault, and is liable for the injury thereby sustained."

State Boards of Registration.

COMING EXAMINATIONS.

Illinois State Board of Health, The Great Northern Hotel, Chicago, January 19-21. Secretary, J. A. Egan, M.D., Springfield.

New York—Three Medical Boards, New York, Albany, Syracuse and Buffalo, January 24-27. H. J. Hamilton, Education Department, Albany.

New Hampshire State Boards, University Club, Concord, February 1-2. Regent, Henry C. Morrison. Concord.

Kansas State Board of Medical Registration and Examination, Topeka, February 14-15. Secretary, G. F. Johnston, M.D., Lakin.

Florida April and October Reports.—Dr. J. L. Niblack, secretary of the Board of Medical Examiners of the Third Judicial district, reports the oral examinations held at Live Oak, April 12 and Oct. 11, 1904. The total number of questions asked was 70; percentage required to pass, 75. Four persons were examined, all of whom passed. No averages were assigned by the board. The following colleges were represented: Tulane University, La., (1904); College of P. and S., Atlanta, Ga., (1903); Harvard University, (1903); Univ. of Pennsylvania, (1899).

Connecticut November Report.—Dr. C. A. Tuttle, secretary of the Connecticut Medical Examining Board, reports written examination held at New Haven, Nov. 9-10, 1904. The number of subjects examined in was 7; total number of questions asked, 70; the percentage required to pass, 75. The total number examined was 20, of whom 12 passed and 8 failed. The following colleges were represented:

College.	Year Grad.	Per Cent.
PASSED.		
College of P. and S., New York	(1904)	83.1
College of P. and S., Baltimore	(1904)	75.6
Yale	(1904) 82.2, (1903)	77, 79.8, 78.9
Cornell	(1898)	82.1
Baltimore Med. College	(1904)	80.1
Univ. of Naples, Italy	(1901)	75.8
Dartmouth Med. Coll	(1903)	79.5
Univ. of Vermont	(1903)	79.9
Tufts Med. Coll	(1903)	76.2
FAILED.		
Baltimore Med. Coll	(1903)	58.8
College of P. and S., Baltimore	(1904)	73.5
Baltimore Medical College	(1904) 74.5, (1903)	74.7
Univ. of Naples, Italy	(1901)	73.6
Maryland Med. Coll	(1904)	73.2
Univ. of Vermont	(1898)	70
College of P. and S., Boston	(1904)	73.8

Dr. C. A. Lindsley, secretary of the Connecticut State Board of Health, reports the written examination conducted by the examining committee of the Homeopathic State Medical Society at Hartford, Nov. 8-9, 1904. The number of subjects examined in was 8; total number of questions asked, 80; percentage required to pass, 75. Two persons were examined, 1 passed and 1 failed. Passed: Hahnemann Medical College, Philadelphia. Failed: New York Homeopathic Medical College and Hospital.

Georgia October Report.—Dr. F. D. Patterson, secretary of the regular Board of Medical Examiners of Georgia, reports the written examination held at Atlanta, Oct. 11, 1904. The number of subjects examined in was 10; total number of questions asked, 50; percentage required to pass, 75. The total number examined was 21, of whom 20 passed and 1 failed. The following colleges were represented:

College.	Year Grad.	Per Cent.
PASSED.		
Maryland Med. Coll	(1904)	75, 75, 80, 81, 82
Univ. of Maryland	(1904)	83, 85, 87, 87
Univ. of Virginia	(1901)	85
Tulane University	(1904)	86
Johns Hopkins University	(1903) 86, (1904)	85
College of P. and S., New York	(1904)	88
Univ. of the South, Sewanee	(1900)	85
Meharry Med Coll	(1904)	79, 77
Med. Coll. of South Carolina	(1904)	84
Jefferson Med. Coll	(1904)	79
Shaw Univ. Med. Dept	(1904)	82
Boston University	(1878)	78
FAILED.		
Chattanooga Med. Coll	(1895)	66

The following questions were asked:

CHEMISTRY.

Give the symbol, atomic weight and valence of each of five elements. Distinguish between the ide and ate terminations. Give formula for potassium chlorid and potassium chlorate. How many minims in one c.c. of water? What is a hydracid? An oxyacid? What is an empirical formula?

PHYSIOLOGY.

Give principal events in gastric digestion. Define blood pressure State the factors which increase and decrease blood pressure State, approximately, the amount of oxygen consumed and the amount of carbon dioxid produced in respiration in twenty-four hours. Describe the secreting structures of the kidneys. Give origin and distribution of sympathetic nerve fibers. Name the three classes into which its ganglia are divided.

MATERIA MEDICA AND THERAPEUTICS

Give symbols of minims, fl drams, fl ounces pint gallon Give difference between anesthetic and analgesic Examples of each (a) Define motor excitants; (b) name the most important, (c) therapeutics and doses (a) Source of turpentine, (b) its composition; (c) action, external and internal; (d) its principal preparation; (e) therapeutics and doses Write a prescription for gastric fermentation containing carbolic acid, bismuth subnitrate, glycerin, peppermint water.

GYNECOLOGY.

Describe the technic for a simple curettage; for curettage after an abortion, and for carcinoma which can not be removed radically. Describe an operation for lacerated perineum; for lacerated cervix Describe an operation for cystocele, rectocele and prolapsed uterus to second degree Give differential diagnosis between ectopic gestation, pyosalpinx and appendicitis Name some of the causes of pelvic suppuration State how you would treat an ovarian or tubal abscess attached to vaginal wall

SURGERY.

Describe an amputation at lower third of the thigh What is surgical shock, and how would you treat it? What is fracture; what is dislocation; how would you treat a compound, comminuted fracture of leg at its middle third? What is varicocele; hydrocele? Describe operation for both conditions What is hernia? Describe an operation for radical cure of inguinal hernia

PRACTICE

Give etiology of poliomyelitis; (a) give some of the most prominent symptoms; (b) give location of lesion. Give the most distinguishing symptoms of smallpox; (a) give the three forms and types of each Give etiology and treatment of lobar pneumonia What is the essential cause of rachitis? (a) give treatment Location of the lesions in acute dysentery in children; (a) give treatment.

OBSTETRICS.

Diagnose placenta previa; (a) describe method of treating same Describe method of handling case of postpartum hemorrhage Give method of handling puerperal eclampsia Name the three stages of labor; (a) describe beginning and termination of each Give the presumptive and certain signs of labor.

DIAGNOSIS.

What is vocal fremitus? What conditions: (a) increase vocal fremitus (b) diminish vocal fremitus? Mention the aids to diagnosis that are of practical use in medicine and surgery Describe the diagnostic characteristics of acute appendicitis Differentiate rheumatic arthritis and joint tuberculosis Differentiate acute cerebral meningitis from syphilitic gumma.

ANATOMY.

(a) Describe the frontal bone and (b) name its articulations (a) Give the names of the muscles of the thigh and (b) state the origin, insertion and action of any one of the muscles mentioned Describe the origin, course and distribution of the renal arteries (a) Describe the portal system of veins and (b) give portal circulation. Describe the sympathetic nerve naming and locating the principal ganglia Give the anatomy of the skin and of its appendages

PATHOLOGY.

Give pathology of interstitial nephritis Define arthritis deformans, and give its morbid anatomy Discuss the pathologic conditions in herpes zoster. Describe pus and give its essential elements Name the bacteria usually associated with ordinary inflammation and suppurative processes

---

Association News.

COUNCIL ON MEDICAL EDUCATION.

Meeting held in Philadelphia, Dec. 28, 1904.

A meeting of the Council on Medical Education of the American Medical Association was held at the Bellevue Stratford Hotel Philadelphia, Dec. 28, 1904. The members of the council, all of whom were present, are Drs A. D. Bevan, chairman, Chicago; V. C. Vaughan, Ann Arbor; J. A. Witherspoon, Nashville; W. T. Councilman, Boston, and C. H. Frazier, Philadelphia

Dr. Witherspoon moved that Dr. George H. Simmons be asked to co operate with the council and that Dr J. H. Musser be regarded as a member ex-officio. Carried.

Dr. Vaughan moved that the council ask for a headquarters in the building of the American Medical Association in Chicago Carried.

Dr. Witherspoon moved that Dr. Vaughan and the chairman constitute a subcommittee to confer with the Board of Trustees with reference to the appointment of a salaried secretary. Carried.

Dr Vaughan moved that the secretary be instructed to tabulate the requirements for admission to medical colleges in those states in which it is fixed by statute Carried.

Dr. Vaughan moved that the secretary be instructed to tabulate the requirements for admission to medical colleges as fixed by the state boards of medical examiners Carried.

Dr. Vaughan moved that the secretary be instructed to tabulate the requirements for admission to medical colleges and the manner in which the credentials of preliminary education are received. Carried.

Dr. Witherspoon moved that the council draw up a scheme specifying the minimum requirements for the entrance to the study of medicine and the method whereby they shall be received.

Dr. Witherspoon moved that the secretary be instructed to ascertain and tabulate the length of the sessions in the various medical colleges. Carried.

Dr. Witherspoon moved that two subcommittees be appointed, one to report a scheme for the minimum requirements for admission to medical schools and the other a scheme on the curriculum. Carried.

The chairman appointed the following committees: Committee on preliminary education, Drs. Bevan, Vaughan and Witherspoon; committee on curriculum, Drs. Bevan, Councilman and Frazier.

Dr. Vaughan moved that the secretary be instructed to request each state board of medical examiners to send one representative to meet the council at its next meeting in Chicago. Carried.

It was decided that the chairman call a meeting of the council at Chicago, April 21 or 22, 1905.

Dr. Councilman moved that the surgeons general of the Army, of the Navy and of the Marine-Hospital Service be requested to send delegates to represent their respective services at the next meeting of the council and that they be informed as to the character of the information which the council desires Adjourned

---

NEW MEMBERS.

New members for the month of December, 1904:

ALABAMA.

Carleton, Wm G, Dudleyville
Curtis R C, Gansey.
Clements, H. C, Benton
Coley, A J, Alexander City.
Drake, J. H, Auburn
Hays, Luther, Cullman.
Hiflin, H T, Birmingham.
Harlan, A L, Alexander City.
Jones, C C, East Lake
Manasco, Titus Carbon Hill.
Milner, G M, Goethite
Pugh, Francis F., Brookside
Prissly, H E, Birmingham
Peter, Thos M, Fayette
Thomas, M C, Belle Ellen
Twitty, F S, Columbia
Webb Alfred P, Atmore.
Watkins, Jas P, Opehika

ARIZONA.

Lennox, J W., Tuscon
Schrader, C. A, Tuscon.

ARKANSAS

Bills, A R, Sulphur Springs
Caruthers, C K, Pine Bluff
Fason, J. T, Grand Lake.

Army Changes.

Memorandum of changes of stations and duties of Medical officers, U. S. Army, for the week ending Jan. 7, 1905:

Siler, Joseph F., asst.-surgeon, relieved from duty at Fort Logan, Colo., and ordered to Fort Meade, S. D., for duty.

Devereux, J. R., asst.-surgeon, relieved from duty at Fort Meade, S. D., and ordered to Fort Logan, Colo.

Reilly, John J., asst.-surgeon, ordered to proceed from Jackson Barracks, La., U. S. Army General Hospital, Fort Bayard, N. M., for treatment.

Mearns, E. A., surgeon, granted thirty days' leave, to take effect on expiration of his present sick leave.

Geer, Charles C., asst.-surgeon, retired from active service on account of disability incident thereto.

Owen, W. O., surgeon, ordered to Fort Leavenworth, Kan., for examination by an army retiring board.

Byrne, Charles B., asst.-surgeon general, detailed member of army retiring board to meet at Fort Leavenworth, Kan., vice Lieutentant Colonel George W. Adair, deputy surgeon general, relieved.

Yost, John D., asst.-surgeon, relieved from duty at San Francisco and ordered to Honolulu, H. T., for duty, relieving Major William B. Davis, surgeon.

Davis, William B., surgeon, relieved from duty at Honolulu, H. T., and ordered to Philippine Islands for duty.

Woodson, R. S., asst.-surgeon, relieved from duty at Fort Clark, Texas, and on discharge from Army and Navy General Hospital, Hot Springs, Ark., ordered to Fort McDowell, Cal., for duty.

Farr, Charles W., asst.-surgeon, in addition to his present duties will perform the duty of attending surgeon, San Francisco.

Wall, Francis M., contract surgeon, granted leave of absence for ten days.

McCall, James H., contract surgeon, ordered from Fort Moultrie, S. C., to Key West Barracks, Fla., for temporary duty.

Burr, Rollin T., contract surgeon, granted an extension of seven days to his leave of absence.

Hayes, Melville, A., contract surgeon, ordered to Vancouver Barracks, Wash., for duty at the expiration of his present leave of absence.

Bell, Leonard P., Hansen, Morris J., and Tuttle, George B., contract surgeons, sailed December 31 on the transport *Thomas* from San Francisco for Philippine service.

Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending Jan. 7, 1905:

Payne, J. H., P. A. surgeon detached from the *Marietta* and ordered home to wait orders.

Ross, John W., medical director, to be placed on the retired list Jan. 11, 1905, under provisions of Section 1444, Revised Statutes, on which date he will reach the age of 62 years. He is ordered to continue duty with the Isthmian Canal Commission after retirement.

Steele, John N., surgeon, detached from the Naval Recruiting Station, Baltimore, and ordered to the *Colorado*.

Elmer, M. K., asst.-surgeon, detached from the *Hancock* and ordered to the Naval Hospital, New York, for treatment.

McMurdo, P. F., A. A. surgeon, detached from the Navy Yard, League Island, Pa., and ordered to the Naval Recruiting Station, Baltimore.

Ferebee, N. M., medical director, having been examined by a retiring board and found incapacitated for active duty, on account of physical disability incident to the service, retired from active service Dec. 31, 1904, under Section 1453, Revised Statutes.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending Jan. 4, 1905:

Brooks, S. D., surgeon, to report on Jan. 10, 1905, to chairman of board of examiners at Fort Stanton, N. M., for the purpose of determining his physical condition.

Nydegger, J. A., P. A. surgeon, granted leave of absence for seven days from Dec. 25, 1904, under Paragraph 191 of the Regulations.

Greene, J. B., P. A. surgeon, granted extension of leave of absence for seven days from Jan. 3, 1905.

Lumsden, L. L., P. A. surgeon, relieved from duty at the Immigration Depot, New York, and directed to proceed to Philadelphia and report to the medical officer in command for duty.

Salmon, T. W., asst.-surgeon, relieved from duty at Philadelphia and directed to proceed to the Immigration Depot, New York, and report to Surgeon G. W. Stoner for duty.

Gregory, G. A., A. A. surgeon, granted leave of absence for seven days from December 30.

Linley, W. J., A. A. surgeon, granted leave of absence for thirty days from Jan. 16, 1905.

Wakefield, H. C., A. A. surgeon, granted leave of absence for three days under Paragraph 210 of the Regulations.

Brown, F. L., pharmacist, granted leave of absence for thirteen days from December 19, 1904. Granted extension of leave of absence for two days from Jan. 1, 1905.

BOARDS CONVENED.

Board convened to meet at Washington, D. C., Jan. 5, 1905, for the physical examination of candidates for the position of second assistant engineer, Revenue-Cutter Service. Detail for the board: Asst.-surgeon General G. T. Vaughan, chairman; Asst.-surgeon A. J. McLaughlin, recorder.

Board convened to meet at Fort Stanton, N. M., Jan. 10, 1905, for the purpose of making a physical examination of Surgeon S. D. Brooks. Detail for the board: Surgeon P. M. Carrington, chairman; Asst.-surgeon Norman Robert, Asst.-surgeon H. G. Ebert, recorder.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine Hospital Service, during the week ended Jan. 6, 1905:

SMALLPOX—UNITED STATES.

Colorado: Larimer Co., Nov. 1-30, 7 cases.
District of Columbia: Washington, Dec. 24-31, 1 case.
Illinois: Chicago, Dec. 24-31, 11 cases, 3 deaths; Danville, Dec. 17-31, 2 cases, 1 death.
Michigan: At 52 localities, Dec. 17-24, present.
Missouri: St. Louis, Dec. 17-24, 18 cases, 1 death.
South Carolina: Georgetown, Nov. 16-Dec. 31, 8 cases.
Tennessee: Dec. 24-31, Memphis, 3 cases, 2 cases imported; Nashville, 8 cases.

SMALLPOX—FOREIGN.

Austria: Prague, Dec. 3-10, 15 cases.
Ecuador: Guayaquil, Dec. 7-14, 1 death.
France: Lyon, Dec. 3-10, 1 case; Paris, Dec. 10-17, 4 cases, 1 death.
Great Britain: Dec. 10-17, London, 2 cases; Newcastle-on-Tyne, 19 cases; South Shields, 5 cases, 2 deaths.
India: Bombay, Nov. 31-Dec. 6, 14 deaths.
Italy: Catania, Dec. 8-15, 1 death; Milan, Oct. 1-31, 1 case.
Mexico: City of Mexico, Nov. 19-Dec. 10, 3 cases, 1 death.
Norway: Christiania, Dec. 10-17, 1 case, 1 death.
Russia: Moscow, Nov. 27-Dec. 8, 5 cases, 2 deaths; Dec. 3-10, Odessa, 1 case; St. Petersburg, 5 cases; Warsaw, Nov. 5-12, 5 cases.
Turkey: Constantinople, Dec. 4-11, 20 deaths.

YELLOW FEVER.

Ecuador: Guayaquil, Dec. 7-14, 3 deaths.
Mexico: Dec. 18-24, Juchitan, 2 cases, 1 death; Texistepec, 2 cases, 1 death.

CHOLERA.

India: Bombay, Nov. 30-Dec. 6, 2 deaths; Calcutta, Nov. 26-Dec. 3, 69 deaths.

PLAGUE.

Arabia: Aden, Nov. 25-Dec. 2, 18 cases, 14 deaths.
India: Bombay, Nov. 30-Dec. 6, 76 deaths; Calcutta, Nov. 26-Dec. 3, 8 deaths.
Straits Settlements: Singapore, Nov. 6-19, 3 cases, 3 deaths.

Cases reported during the week ended Dec. 30, 1904:

CHOLERA.

India: Bombay, Nov. 22-29, 1 death.
Russian Empire: Erivan, Nov. 22-28, 914 cases, 363 deaths; Jelisavetpol, Nov. 16-22, present; Tachken, Nov. 27, 18 cases, 8 deaths; Tiflis, Nov. 16-22, present.
Turkey in Asia: Nov. 28, 72 cases, 43 deaths.

PLAGUE.

Africa: Cape Colony, Nov. 6-19, 5 cases.
Arabia: Aden, Nov. 18-25, 19 cases, 12 deaths.
Argentina: Tucuman Province, Nov. 18, 1 death.
Brazil: Bahia, Nov. 12-26, 6 deaths; Rio de Janeiro, Nov. 6-27, 101 cases, 35 deaths.
Egypt: Tukh District, Nov. 19-26, 2 cases, 2 deaths.
India: Bombay, Nov. 22-29, 74 deaths; Calcutta, Nov. 19-26, 8 deaths; Karachi, Nov. 20-27, 14 cases, 14 deaths.
Paraguay: Ascuncion, Oct. 6, 20 cases weekly, estimated.
Peru: Guadelupe, Dec. 7, present; Lima, Nov. 1-15, 6 cases.

Medical Organization.

ORGANIZATION IN TENNESSEE.

The approaching meeting of the Tennessee State Medical Association leads the *Southern Practitioner* to discuss "this subject of so great importance to every member of the regular medical profession who has his own interest and that of his clientele at heart." The editorial is in part as follows: "The method now in force in so many states is unquestionably the most satisfactory, and promises by far the most beneficial results possible. It is distinctly representative, it places the foundation and basis of representation where it should be, at the bottom; the county societies being the only correct criterion and proper means and method of determining the standard of all who are entitled to the courtesies, the advantages and privileges of membership in our state and national associations.

"What does the member in an east Tennessee county know of the ethical standings of those in the western or middle divisions of our state? Or what can those in one county or section even not as far removed know of the character of others than those in their own vicinity? If a physician is acceptable to his home associates, he should certainly be acceptable to other members of the profession in other localities. This is the method adopted by all organizations, and can but prove most satisfactory in ours. Much might be said in behalf of the recent measures suggested by the American Medical Association for the profession in all states, and the progress so far made is most gratifying, indeed, and shows that it is being almost universally accepted. . . .

"We can but regret that the 'Old Dominion,' the 'Mother of States,' still lags back, and so far has refused to align herself with the large number of her sister states, north, south, east and west. We can but attribute it to a degree of unwise conservatism, a disposition to hold on to old methods, but it is not progressive. While our professional brothers in Virginia have done well, yes, better than a number of others under the old but somewhat loose and indefinite method of the past, we most heartily and sincerely believe that they can do still better under the new order, and we are surprised that its especially representative features have not appealed more strongly to them. However, we can afford to wait if they can, and we firmly believe that it is only a question of time.

"While we have accomplished much in our own state, yet we have not done altogether as well as our sincere desire, but what has been done has been most satisfactory, and we were perhaps too sanguine. We have now sixty-five counties with organized medical societies on the roll of our state association, with a membership of something over 1,200, and although these are the most populous and thickly settled sections of the state, we had hoped that others would have been added before this. Owing to the large area and sparse population, the defective roads and means of reaching them, the same effort has not been made by the committee on county organization that was continued over last April from the preceding years, as in other counties. In our opinion, the committeee has not been as active and energetic as it should have been. This, however, can be remedied in the months yet preceding the annual meeting of the state association. This statement is not made in a captious or critical manner as regards the action of the committee, and we take this method of calling their attention to the matter, and wish to put them on their mettle as it were, and most sincerely hope that an aggressive campaign will at once be entered on. The sooner work is commenced the better results we will have.

"In the thirty counties in which so far no organization has been officially reported and enrolled in the state association, there is, according to the census of 1900, a population of 301,317, while the other sixty-five counties embrace a population of 1,719,099. Even in some of these counties, county medical societies have been organized. In some of these counties the sparse population has necessitated but a limited number of physicians, not sufficient to form an organization, . . . yet we hope that . . . in those counties . . . two or more may unite in the formation of an organization, for which due provision is made in the constitution and by-laws of the state association.

"We have had the opportunity of visiting a few of the county societies during the past year, and in every instance we have found the members showing an interest that can but redound to their good. In two of these counties no organization had previously existed, and but few of the profession there had ever taken much interest in our state meetings, yet in these we found an active membership that we feel confident will be perpetuated and increased. From other counties . . . we have received very encouraging reports. Interesting and harmonious meetings, and in every instance where a county society has been organized for as much as a year, there is a far more agreeable and harmonious feeling between the members of the profession than had previously existed."

Continued Success in Michigan.

From a letter received from the Secretary, Dr. A. P. Biddle, we learn that the membership of the Michigan State Medical Society at the beginning of 1905 was 1,761, a gain of 106 over the year 1903. Considering the enormous gain of 1903 over previous years, the conditions are certainly very satisfactory and the workers in Michigan are to be congratulated.

Society Proceedings.

WESTERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

Fourteenth Annual Meeting, held in Milwaukee, Wis., Dec. 28-29, 1904.

(Continued from page 58.)

Operation for Undescended Testicle.

Dr. E. M. Sutton, Peoria, Ill., reported the case of a boy, 11 years of age, a cryptorchid who suffered from strabismus and nervousness, but otherwise was well. In making an incision in the inguinal canal, the testicle was found above the internal ring free; the cord was retained by a band extending posteriorly toward the median line, and upward opposite the second lumbar vertebra. Blunt dissection was resorted to until the cord was freed and the testicle deposited easily in the bottom of the scrotum without tension. The remaining step of the operation consisted in making a buttonhole incision through the bottom of the scrotal sac, posterior to its middle, where the skin is less elastic, catgut stitches inserted through the edges of the skin, and the tunica albuginea in a way which held the end of the testicle attached to the skin, necessitating healing by granulation. Convalescence was uncomplicated; the testicle was permanently fixed in the bottom of the scrotum and did not atrophy.

Objections to attaching the testicle to the bottom of a movable sac are valid, since experience demonstrates the futility of such a method. The Katzenstein operation of taking a flap from the inner side of the thigh is a step in the right direction. However, with the modifications employed in the author's case, considering the satisfactory results, the surgeon can fix the testicle absolutely. Dr. Sutton also reported a case of aneurism of the superior mesenteric artery on which he had operated.

Splenic Anemia.

Dr. Palmer Findley, Chicago, reported a case of splenic anemia in which he removed the spleen with good results. He offered a word of caution as to the hasty diagnosis of splenic anemia wihout giving due consideration to other possible causes for splenic enlargement associated with a secondary anemia, such as malaria and syphilis, and advised splenectomy for only the rapidly progressive cases.

High-Frequency Electricity.

Dr. E. M. Sala, Rock Island, Ill., related his personal experience with the d'Arsonval high-frequency current, and reported cases in which the immediate results are gratifying. He is convinced that the d'Arsonval-Odin apparatus has a very promising future.

The Care of the Axilla After Excavations for Malignant or Infective Lesions.

Dr. John B. Murphy, Chicago, said that extensive dissection of the axilla is not infrequently followed by contracting, painful cicatrices, limitation of motion, edema, neuralgia, etc. These can be relieved or avoided by (a) line of skin incision, (b) immediate grafting or transplantation, (c) muscular implantation and (d) muscular conservation.

Bone Plug for Bone Cavities.

Dr. James E. Moore, Minneapolis, Minn., stated that in January, 1903, von Mosetig reported a large number of successful results from the use of a new bone plug. The plug does not act as a foreign body, nor does it act as a culture medium. It possesses the inhibitory and medicinal properties of iodoform without causing iodoform intoxication. His experience with this material, although limited, has been sufficient to satisfy him that better results can be obtained in treating bone cavities with it than by any older method, and in illustration he reported four recent successful cases. He believes that cases can now be treated successfully with this bone plug in which formerly amputation was performed, as, for instance, in cases of tuberculosis of the wrist and ankle joints.

Excision of the Semilunar Ganglion in Facial Neuralgia.

Dr. A. E. Halstead, Chicago, reported seven cases. The pain may return after the removal of the ganglion. In his cases each ganglion was carefully examined by a competent microscopist. In each ganglion elements were found, and the gross anatomic characteristics of the organ were preserved.

DISCUSSION.

Dr. John B. Murphy stated that in his twelve cases there were four deaths. This large percentage caused him to abandon the operation. Since his last report he has had only one recurrence of neuralgia after the injection of osmic acid.

Mortality, Disability and Permanency of Cure in Surgery.

Dr. Charles H. Mayo, Rochester, Minn., selected this subject as the President's Address. This will be published in The Journal.

Surgical Diseases of the Pancreas.

Dr. D. C. Brockman, Ottumwa, Iowa, said that recent studies of the pancreas show the importance of internal secretion from the islands of Langerhans; also the influence of regurgitation of bile into the pancreatic ducts as a cause of pancreatic inflammation. He mentioned biliary disturbance as the chief cause of pancreatic disease, and stated that pancreatic cysts are believed to be mostly due to this cause. He reported three instructive cases of cyst of the pancreas, and then gave an outline of inflammatory troubles, with special reference to the diagnosis and treatment of acute and chronic pancreatitis.

Cysts of the Pancreas.

Dr. D. W. Basham, Wichita, Kan., referred briefly to the physiologic anatomy of the gland, in order to elucidate the principles underlying the formation of a cyst of this organ. He recounted the symptomatology, and pointed out the difficulty attending the diagnosis. As to treatment, Gussenbauer was the first to marsupialize the sac, and since then this has been a favorite procedure with most surgeons. The only question regarding this method is whether to attach the sac to the abdomen and incise at once or to operate twice. If there is plenty of time and the cyst is not so large that a day or two may make any difference in the result, he thinks it is better to operate in two stages, stitching the sac to the peritoneum and muscles, and opening two or three days later. Excision of the sac is not often practical, but may sometimes be attempted. Often such a course will expose the patient to the risk of contaminating the peritoneal cavity with pancreatic secretions. He reported the case of a tumor of the pancreas in a woman 62 years of age. The tumor was removed. The patient left the hospital at the end of seven weeks, and he has not seen her since. The woman's dyspeptic manifestations were better after the operation than before, but were not entirely relieved. About the first of December the patient began to have serious trouble with her stomach and called a physician, who outlined a tumor in the region of the pylorus, which he diagnosed as cancer of the stomach.

DISCUSSION.

Dr. William D. Haggard thinks inflammations of the pancreas will occupy the most prominent position in the future development of surgery. Disease of this organ is closely allied to surgery for lesions in the upper abdomen. When one stops to think how our knowledge has been amplified in the last two years relative to this sequestered organ, and when one considers that many cases of so-called gastritis, intestinal obstruction, etc., are after all probably instances of pancreatitis, it makes surgeons realize that the lesson has been appreciated, but we have not yet mastered the diagnosis of this as well as other lesions; nevertheless more attention should be addressed to lesions of the pancreas than has been done in the past. He referred to the three types of infection, and called attention to the excellent work done by Opie, Robson and others.

Dr. Brockman has had four cases of pancreatic cyst in the last twelve or fourteen years.

Excision of Elbow Joint for Ankylosis.

Dr. B. Merrill Ricketts, Cincinnati, Ohio, drew the following conclusions:

"(1) Excision of the elbow joint for ankylosis, due to any cause, at any age, is a most rational procedure. (2) If possible, it should be done before or at the time ankylosis is complete. (3) A posterior median incision is the most practical. (4) With care the operation can be done without injury to blood vessels or nerves. (5) Drainage should always be provided for. (6) The arm should be placed on a right angle splint. (7) Results are better when only the articulating surfaces are removed. (8) If there is complete bony union of the articulating surfaces, much more bony tissue must be sacrificed, because disarticulation can not be accomplished. (9) All soft structures cut transversely will unite, but new insertions are formed which destroy their function. (10) All attachments of tendons and muscles should be preserved. (11) All periosteum should be preserved. (12) If excision of the joint is complete, leaving only the ends of the shafts, flail joint can be prevented by approximating their ends with kangaroo tendon at the time of primary operation. (13) Wire or nail may be used, but their removal sooner or later will be imperative. (14) Flail joint rarely results from any form of excision, but is more likely to be found following excision of the entire joint. (15) If flail joint results, a mechanical device may be employed. (16) Injections of alcohol or one or more of the various astringents will increase fibrous tissue, both in quantity and density."

Operative Treatment of Fractures and Sprains.

Dr. A. E. Benjamin, Minneapolis, Minn., stated that all fractures should be examined with the *x*-ray to diagnose positively and to locate them. The ordinary form of treatment of even simple fractures often results in a deformed and crippled limb. The term ununited fracture is a myth; the condition is invariably due to some preventable cause. The habit of using the *x*-ray in all fractures leads to more operative measures, although without its use diagnosis is frequently impossible and treatment uncertain. There is frequently as great a subcutaneous injury from a simple fracture as in a compound fracture, and it is essential that an operation should be performed in such cases in order to prevent a lasting injury to the nerve and muscle tissue. By an operation on these fractures drainage is established, pain and fever lessened, exostosis and the organization of the exudate are less permanent, and necessarily there follows less permanent injury to the soft structures. Associated with fractures there is frequently a sprain or a tearing of ligaments and dislocation of cartilages. The progress of a joint that has been sprained is often slow and discouraging, resulting in a weak and insecure union of ligaments. It is advisable to operate on some sprains, especially where there is a great deal of exudate and pain. By the operative method drainage is established, pain relieved, the ligaments can be stitched in their natural position, the convalescent period is shortened, and a greater proportion of cures result.

The Surgical Considerations of Gastric Dilatation.

Dr. A. M. Pond, Webster City, Iowa, stated that in his last three cases of gastric dilatation due to impairment of the stomach wall, he modified the standard operation. Sufficient time, however, has not elapsed to warrant a description of the operation. In each instance a very satisfactory result was obtained. The success of the operation depends on the patentcy of the pyloric orifice and the ability of the gastric muscle to regain its normal tone. The author believes that gastric dilatation is usually a sequence rather than a primary cause of discomfort, and that it owes its presence to some disturbance of the elemental dynamics of digestion.

Treatment of Acute Perforations of the Upper Abdominal Viscera.

Dr. Van Buren Knott, Sioux City, Iowa, pointed out the importance of the early recognition of such an accident. The symptoms of gastric or duodenal perforation will usually be more intense than those of perforation of the gall bladder. The previous history of the case is of importance in making a differential diagnosis. The treatment is successful in direct ratio to the promptness with which it is instituted. The resulting peritonitis is the most important outcome of the accident, and its treatment in the various cases is similar. He emphasized the value of posture in treatment.

Pneumatocele.

Dr. L. L. McArthur, Chicago, reported a case of pneumatocele, a gas-containing tumor of the cranium. Only 32 cases of this condition have been recorded since 1741. It always originates in connection with either the mastoid or frontal sinuses. It is not to be confounded with emphysema, which is gas in the cellular tissue. Pneumatocele is gas between the pericranium. Incident to the elevation of the periosteum are secondary bony outgrowths, giving the tumor a peculiar "feel." In the preantiseptic era the simple benign pneumatocele became a dangerous affair, because of the frequent connection with the mastoid sinuses, with the potential septic meningitis. Since antiseptic surgery has become well established all these cases recover.

The Value of Skiagraphy in Fractures.

Dr. H. A. Sifton, Milwaukee, Wis., is of the opinion that, when it is possible, the Roentgen ray should be used in the treatment of every fracture. Some urge its use in the obscure or complicated cases only, but the difficulty with this plan is that one can never tell whether or not a fracture is complicated until a radiograph of it is taken. It is the surgeon's duty to look on every case of fracture as a complicated one until it has been shown to be otherwise by a good radiograph. A good radiograph is of value for future information from a forensic standpoint, but no radiograph should be admitted as evidence in any medicolegal dispute unless both parties to the dispute know the conditions under which the radiograph was taken.

DISCUSSION.

Drs. L. L. McArthur, J. W. Andrews, C. E. Ruth, A. I. Bouffleur, M. L. Harris, A. E. Benjamin all concurred in the opinion that the *x*-ray is an important confirmatory aid to the surgeon, but that radiographs should not be admitted as evidence in a court of law.

The Practical Significance of Certain Common Symptoms in the Upper Abdomen.

Dr. J. F. Percy, Galesburg, Ill., said these symptoms are pain from ulcer of the stomach and cholecystitis, with or without stones, and the action of the gastric juice on an open ulcer, either in the stomach or duodenum. Another source of pain is the formation of gas from inhibited peristalsis, due to ulcer or adhesions arising from it. Vomiting was also referred to as one of the symptoms of disease in this region, but in the author's experience it is not as frequent as nausea. Two methods were referred to as aids to the location of lesions in the upper abdomen, one being light finger percussion, eliciting pain over the inflammatory focus, in patients not too obese, and the other the resistance of the costal cartilages on the right side in inflammatory conditions of the gall-bladder and in ulcer of the duodenum or pylorus, as recently pointed out anew by Elliott. The author laid special stress on the effects of chronic infections of the liver and pancreas from ulcer of the stomach and persistent cholecystitis, and cited cases in point. He stated that some of these cases are rarely diagnosed correctly. Biliousness and dyspepsia are the words most frequently used as descriptive of the diagnosis, and on this the treatment is based. The author stated further that a persistent infection will, in an appreciable number of cases, cause death, regardless of the form of treatment which may be instituted, because of the alteration in the functionating tissues of the liver and pancreas.

DISCUSSION.

Dr. John B. Murphy congratulated the essayist on bringing out with greater force the fact that a differential diagnosis between lesions of the pyloric area of the stomach, the head of the pancreas, and the gall-bladder is extremely difficult, and also that he emphasized the periodicity of exacerbations in ulcers of the stomach. A large number of cases of ulcer of the stomach have pronounced exacerbations. They are practically well in the period between the attacks.

Dr. Alex. Hugh Ferguson stated that sudden pain referable to the epigastric region, with tenderness over the gall-bladder, shows that the seat of the trouble is within the gall-bladder, the stone or stones being engaged in the cystic duct. Pain occurring while the patient is in a quiescent state, or occurring after the patient has gone to sleep, points to the gall-bladder rather than to any other organ. An occasional lancinating pain, referable to the region of the gall-bladder and its ducts, points to carcinoma. Pain referred to the region of the ducts is more characteristic of gall-stones. In cases of stone or tumor of the kidney, as well as in tumor of the suprarenal capsule, pain is generally referred to the back. Pott's disease should not be overlooked. Pain referred to the testicle, and radiating into the genitourinary tract, points to the kidney as the seat of the trouble. Still, pain is referred sometimes to these regions from other conditions than stone in the kidney.

Dr. William D. Haggard said that while expertness and refinement in diagnosis are desiderata, surgeons must realize that many of the cases under discussion are not amenable to the niceties and refinement of diagnosis to which attention has been drawn. He referred to the importance of a well-taken clinical history, saying that a great deal of dependence should be placed on it.

Dr. B. B. Davis protested against the habit of making incisions without having made a careful and sufficient study of the case beforehand, but he said that man is more dangerous who does not make such incisions occasionally than the one who does make them before he has made accurate diagnoses. He related a case which he thought to be one of cholelithiasis, yet on operating he found a large appendix turned up underneath the gall bladder, with dense adhesions around the cystic duct. There were no stones found in the gall bladder; it was perfectly patulous, and after freeing the adhesions he could squeeze the bile out without any trouble. He did nothing to the gall bladder, simply removed the appendix, and thus far relief has been complete.

CALIFORNIA ACADEMY OF MEDICINE.

Regular Meeting, held in San Francisco, Nov. 22, 1904.

The President, Dr. T. W. Huntington, in the Chair.

Resection of Chest Wall for Recurrent Carcinoma of Breast.

Dr. Emmet Rixford exhibited a patient in whom a portion of the chest wall had been resected for recurrent carcinoma. The patient was seen Aug. 15, 1903, with a suppurating carcinoma of the breast, which had been first noticed four months previously. After primary cleansing of the suppurating area with pure carbolic acid, a Halsted operation was performed and the wound healed without difficulty. Eleven months later there was a recurrence at the site of the original operation and the recurrent tumor was adherent to the chest wall. At a second operation this tumor was removed. It was necessary to excise portions of the first and second ribs and about half an inch of the left side of the sternum. The left pleural cavity was opened, the lung collapsed, and the respiratory movements of the mediastinum and heart could be plainly seen. The respirations became very rapid, but if the opening into the pleural cavity was closed by a hand or a towel the lung seemed to expand and the respirations became better. The wound was closed by a large skin flap. Five months after the second operation there are no signs of a recurrence. The skin flap is drawn in at each inspiration. This is the fourth operation of this character which has been performed by Dr. Rixford. One of the other patients subsequently died of local metastases, one developed local nodules which disappeared under x-ray treatment, and one other beside the one here exhibited as yet has shown no signs of metastases. The operation is only justifiable when the patient is in good condition and when there are no distant metastases.

DISCUSSION.

Dr. Barbat suggested the use of some form of artificial respiration in such cases, similar to that used in physiologic experiments. The Sauerbruch pneumatic cabinet, if accessible, would find a place in these operations.

An Unusual Case of Anemia.

Dr. G. H. Evans and Dr. Mary Halton reported a case of anemia of the aplastic type. The patient entered St. Luke's Hospital Sept. 21, 1903. Six years previously he had had "blood poisoning" in the right foot, and three years previously he had lost his right eye in a shooting accident. About two months ago he had a severe nose bleed, and has had another less severe one since then.

Physical examination showed a well-nourished, pale man, with systolic murmurs over the base of the heart and a large ulcer on the outer aspect of the lower part of the right leg. The blood showed 1,150,000 red corpuscles, 7,300 leucocytes, and 30 per cent. of hemoglobin. A differential count of the white cells showed polymorphonuclears 6 per cent., small lymphocytes 91 per cent., large lymphocytes 2 per cent., and eosinophiles 1 per cent. No nucleated red cells were seen, and there was no marked poikilocytosis and no polychromatophilia.

During his stay in the hospital he had several severe nasal hemorrhages, an irregular fever, and, after gradually becoming weaker, he died ten days after admission. Shortly before death his blood showed 770,000 red corpuscles, 2,300 leucocytes, and about 10 per cent. hemoglobin. The differential count of the leucocytes did not differ essentially from the former count except in the absence of eosinophiles. No parasites nor eggs of parasites were found in the feces.

The autopsy and bacteriologic findings were negative except for the deposit of pigment, giving the reaction for iron in the liver and a moderate enlargement of the hemolymph glands about the inferior vena cava. The spinal cord and the bone marrow of the long bones were not examined.

The case here presented may possibly have been a leukemia with a reduction in the number of leucocytes. Such reductions have been observed during the course of acute infectious diseases, and one of the authors has seen it occur coincidently with pregnancy. On the other hand, the case suggests pernicious anemia in many of its features, viz., the high-color index, the marked reduction of both the red and white cells and the autopsy findings. As has been said, no nucleated red corpuscles were found during life, but later, after a search through about half a millimeter of blood, two megaloblasts were found. The case appears to belong to the class described as aplastic anemias, which are in all probability cases of pernicious anemia without the customary regeneration of blood by the bone marrow.

DISCUSSION.

Dr. George Blumer reported a similar case of anemia which he saw recently. During life the patient showed an irregular fever, a palpable liver, and bleeding hemorrhoids with an ulcer in the rectum. The red corpuscles varied from 1,500,000 to 1,100,000, the leucocytes from 4,600 to 3,400, and the hemoglobin from 20 to 19 per cent. Very few nucleated red cells were found, and these were either normoblasts or transitional forms. An average of several differential counts showed polymorphonuclears 7.5, large lymphocytes 2.3, small lymphocytes 90.2 *per cent.* and no eosinophiles. The autopsy showed in general the changes of pernicious anemia except that the signs of regeneration in the bone marrow were very slight. He agreed with the preceding speakers in regarding this type of anemia as pernicious anemia without a reaction on the part of the blood-forming organs.

Dr. Brunn described a child who had enlargements of the liver, spleen and lymphatic apparatus, with marked anemia and with 6,900 leucocytes, which were mostly small lymphocytes. The child died of a streptococcus angina.

Dr. Evans is inclined to regard the last case as one of lymphatic leukemia, with a concomitant infection.

PHILADELPHIA COUNTY MEDICAL SOCIETY.

Regular Meeting, Nov. 23, 1904.

The President, Dr. Roland G. Curtin, in the Chair.

Value of the X-Ray in Diagnosis.

Dr. **L. J. Hammond** reported the case of a patient who had been suffering with pain in his right wrist for more than two years. There was no tenderness to touch nor any visible signs of inflammation, and it was only when the wrist was abducted that the pain was intense. The condition had been variously diagnosed as rheumatism, sprain, tubercular periostitis and tenonitis. Treatment for these had given no relief. The *x*-ray revealed a fracture of the scaphoid bone, the fragments of which were united by a very loose fibrous connection. The interposed fibrous tissue was removed, perfect apposition of the fragments was secured and they were held together by two small silver wire sutures. There was perfect restoration of all the wrist movements, with entire absence of pain.

An interesting point was that, while the patient recalled having fallen with the hand outstretched and abducted, no immediate symptoms of pain, swelling or ecchymosis were sufficiently pronounced to demand surgical aid. Dr. Hammond said that experience in the surgical out-patients' department of city hospitals showed the frequency of fractures of the bones of the wrist and ankle joints without recognition. The only treatment is to secure bony union, which can be done only by securing perfect apposition, either by wiring or by any other of the mechanical means for this purpose. Dr. Hammond believes wiring to be by far the most reliable procedure.

DISCUSSION.

Dr. **Charles Lester Leonard** referred to the obscure character of these fractures. They can only be demonstrated by the *x*-ray. This means of diagnosis is particularly valuable in the slight injuries occurring about the joint, the sprains, fractures and chipping of small fragments within the joint which lead to incapacity of function so important to those depending on their hands as a means of livelihood. He believes it the duty of the surgeon in injuries about the joints to have *x*-ray examinations made to exclude these fractures, for a negative diagnosis is of much value to the patient in a saving of time and in the immediate institution of the proper treatment.

Dr. **Hammond** agreed with Dr. Leonard that fractures of this kind are not rare, are sure to be overlooked and the condition treated as a sprain or as some constitutional fault.

Typhoid Fever in Philadelphia.

Dr. **Randolph Faries** said that typhoid fever does not exist in Philadelphia to the alarming extent that the general public is given to believe. The apparently large proportion of the disease in this city he attributed to three conditions: Errors in diagnosis, cases contracted elsewhere, and duplicate cases. He enumerated sixteen diseases which may be mistaken for typhoid fever. No case should be reported to the board of health as typhoid fever unless a Widal reaction has been taken and unless the urine, feces and catarrhal secretions also have been examined. Especial care should be taken in examining the liver and spleen, in noting the course of the temperature, the nature of the pulse, the amount and kind of stupor, as well as the nervous symptoms present, and a blood count should be made. Dr. Faries believes that, with the municipal improvements of cleaner streets, better surface drainage and perfect under drainage, the abolition of cesspools, houses constructed with better scientific ventilation, careful disinfection of everything whereby typhoid may be transmitted, extreme vigilance on the part of the health authorities in reference to impure milk, adulterated foods, impure water, and a constant instruction to the general public in reference to those foods by which typhoid is often contracted, such as raw oysters, lettuce, overripe and unclean fruits, etc., it is reasonable to suppose that there will come a time when very few cases of typhoid fever, if any, will exist in Philadelphia.

DISCUSSION.

Dr. **Edward Martin**, director of the Bureau of Public Health, observed that statistics show a certain amount of transference of typhoid fever from one case to another, and that the reason for reporting the cases, so far as the public health is concerned, is to prevent this direct transference and to take precautions against a local epidemic. In most cases of typhoid, in the well-to-do, the community is properly protected, but among the cases seen by the corps of assistants to the Bureau of Health the importance of a report is very great. The bureau would rather have a report of a case which is not typhoid, and look it up, than to have the case unreported and a possible spread of the contagion. Disinfection of the dejecta he regards as difficult and thinks we should not be indifferent to the people who get water below our pollutions. In the walking cases the urinary secretions may remain for a week a prolific source of infection. The Bureau of Health has made a statistical study of wells and cesspools and has been astonished to find upward of one hundred in such juxtaposition that the water must be infected. He regards the water supply as the main source of infection and feels that Philadelphia will still be a typhoid-cursed city until it has a filtered water supply.

Dr. **Faries** said that many of the cases are reported too quickly, but that the remedy is difficult since the assistant inspectors of the health department are not allowed to interfere with the family physician. It is, therefore, manifestly the duty of the family physician to be especially careful in his diagnosis. While it is possible to ascertain the exact number of cases outside of the city, and the duplicate cases, it is not possible to estimate those cases of error in diagnosis.

Trachoma Successfully Treated with the X-Ray.

Drs. **W. S. Newcomet** and **J. P. Krall** exhibited a girl of 18 who had been subjected to all the operations for the cure of trachoma without success. She was treated with the *x*-ray from July, 1903, until Jan. 1, 1904. The inflammatory reaction was so intense that it was thought better to abandon the treatment. Later, however, it was found that she could count fingers at close range. The cornea of the eye was entirely clear and only with special illumination could there be seen fine blood vessels. The eye not treated with the *x*-ray showed all the symptoms that the treated eye formerly exhibited. The condition of the patient had been present since infancy, and she had been unable to see across the room. Treatment was given every other day for five minutes for about six weeks, when a burn developed and treatment was withheld. Dr. Newcomet believed the result to be due to the accidental burn produced in the course of treatment.

DISCUSSION.

Dr. **Jay F. Schamberg** referred to a case of trachoma in the Polyclinic Hospital, in which the vascular injection of the cornea was less pronounced than in the case exhibited, but which had a tremendous growth of vegetative excrescences on the conjunctivæ. The man has received about twenty treatments. The growths have almost entirely disappeared in both eyes and the conjunctivæ are fast approaching normal. In technic the eye was exposed by means of a clamp, the upper lid was everted and the clamps held by weights.

Dr. **George E. Pfahler** referred to the paper of Dr. Mayo of London. He did not understand that any burns had been produced in the cases of Dr. Mayo. The face at first was covered with a mask, but later no precaution was taken. The soft tube was placed about nine inches from the patient and the treatments were from three to five minutes in length.

Dr. **Charles Lester Leonard** regarded the case as of much interest both from the aspect of the ophthalmologist and from that of the *x*-ray worker. The condition still present in one eye which had been symptomatically cured in the other he thought showed a marked illustration of the possibilities of the *x*-ray in chronic conditions about the eye. The value of the method, he believes, depends not on the production of a burn, but on a specific action of the *x*-ray on the autolytic ferments contained within the cells themselves. The *x*-ray, he stated, is not a cure-all, but an agency which assists nature by stimulating to action the self-contained elements within the cells.

Dr. **M. K. Kassabian** agreed with Dr. Leonard regarding the stimulating and irritating action of the *x*-rays on the tissues, but he believes further that there is a germicidal or inhibitory action on the germ. He covers the Crookes tube with a dark cloth and darkens the room, preventing injury to the patient from the light because of the excessive photophobia. He attaches the everted eyelids by adhesive plaster to the skin. He had four cases in the Philadelphia Hospital, two acute and two chronic. The acute cases had severe photophobia and lacrimation and were improved after four or five exposures.

DR. NEWCOMET said operators in London are careless. One-half of the men used little or no protection in the treatment, and one man used only wet gauze. Dr. Newcomet uses a shield and as much as possible avoids handling the cases.

Travel Notes.

XXII.

AN INTERSEMESTRAL EXCURSION.*

LEWELLYS F. BARKER, M.D.
CHICAGO.

The division of the university year in Germany into two semesters with a good month's vacation between them in the spring has some special advantages. For the vacation is a real one; the student finds the clinics and the laboratories closed to him during this period; if he wishes to work he must apply at some private laboratory. The month gives excellent opportunity to teaching staff and students for quiet recreation or travel. Many teachers spend the time in a walking, bicycling or boating tour; others take advantage of this season to visit neighboring or distant colleagues, consult various authorities on particular phases of their research, examine new methods or new apparatus recently reported, or attend some one of the various congresses usually held in this period.

Despite the train of snows, rain, frosts and storms which winter, more than usually dreary in Munich, led "out of his Scythian cave," the city had been so interesting, profitable and enjoyable that it was with regret that one made up his mind to leave it. The home instinct which lies deep in human nature soon makes itself felt when once one is comfortably settled, even in a foreign city; it requires an effort to give up more permanent lodgings and enter again on the itinerant life. But the medical traveler who has only a year at his disposal dare not let his "high hopes faint on the warm (*sic*) hearthstone" of a German pension. The vacation must be utilized as well as the semesters if the year is to bring its full quota of experience.

NUREMBERG.

It seemed almost paradoxical to go to old Nuremberg to visit a new hospital, but it is nevertheless true that the American visitor can not afford to neglect a visit to the General Hospital of this artistic "City of the Empire" if it is a part of his mission to look into modern hospital construction in Europe. Just before leaving New York it had been my good fortune, thanks to Dr. Painter's courtesy, to examine in some detail the architecture and arrangements of the New York Lying-in Hospital. It proved to be a great help to have the main features of this triumph of hospital building in mind for comparison when visiting the Nuremberg Hospital and subsequently others of the newer European hospitals

The remarkable commercial development of Nuremberg in recent years has led to such a rapid growth of the city that it now has more than a quarter of a million inhabitants; this fact, together with the compulsory insurance of the working classes against disease in Germany, led to such an increase in the number of applicants for hospital treatment that, a few years ago, the building of a new hospital by the city became a matter of absolute necessity. It took some three years to build it. The plans were so carefully drawn and the work so well executed that the new City Hospital in Nuremberg has served for a model for several others which have been planned since; the new hospitals in Budapest, Copenhagen, Odessa, St. Petersburg, Prague, Rotterdam, Warsaw and Vienna have all, it is said, borrowed and adopted ideas from it.

The hospital, which is situated in the quiet northwestern part of the city, consists of thirty-one buildings, entirely separate from one another above ground, but all connected by means of subterranean tunnels for the conduction of heat, water and light. The buildings, with the exception of the administration and the director's dwelling, are simple externally —almost painfully simple—but one can not refuse to admire the wisdom which curtailed external adornment in order that the more important internal arrangements might be made as nearly perfect as possible. At present there are 946 beds—252 surgical, 417 medical, 121 for venereal diseases (!), 45 for skin diseases, 31 for insane patients, and 80 for overflow cases, medical and surgical. The money for the buildings was supplied by the city and the annual support, outside of the fees derived from patients, comes from the same source. The city government is represented by a civil supervisor, the so-called *Pfleger des Krankenhauses*. The whole medical administration, however, is subordinate to the medical director, Dr. G. Merkel, one of the best known and deservedly popular medical men of southern Germany. The housekeeping, bookkeeping and accounts are in the hands of the business manager, the so-called *Krankenhaus-Verwalter*. The dangers of conflict among these three factors of the administration are avoided by means of rigid definition of the functions of each; each has his own rights and each his own duties, and they are so specific that the machine runs, it is asserted, without friction. The medical director is also the physician-in-chief to the first medical subdivision of the hospital. The other chiefs of subdivisions are chosen from practitioners in the city; each has his own assistant physicians, nurses and orderlies directly responsible to him, and regarding the treatment of the patients in his wards he has a free hand Each "chief" is responsible for the general hygiene, diet and therapy in his particular division; he has to make a daily visit, in the early morning, and where necessary an evening visit also. If called at other times by the assistant physicians on account of an emergency or the grave condition of a patient, the "chief" is expected to promptly respond. Among other duties each chief is required to see that the histories of patients are regularly kept and to make sure that the assistants of his division perform their duties in full. It is his duty to see that an autopsy is performed by the pathologist on every patient dying in his division and to make sure that a proper protocol of the same is preserved. A special paragraph in the regulations states that "it is expected that the heads of divisions will, in the interests of science, utilize and work up as far as is possible the rich observation material at their disposal, calling on the assistant physicians to aid them in their work" If differences of opinion arise as to the medical duties the director has the deciding word.

All over south Germany the hospital nursing is in ecclesiastical hands; so in Nuremberg the nursing is in the charge of a superior deaconess of the Evangelical Lutheran Deaconess Institution of Neuen-Dettelsau. The orderlies (or male nurses) are also deacons. Non-ecclesiastical nurses and orderlies are employed in the insane wards and in the male syphilitic wards only. The hospital is supplied with all modern conveniences in the way of telephones, electric clocks, ice machine and the like, just as in our American hospitals. The assistant physicians live on the first floor of the administration building; in this building, too, are reading rooms, library, consultation rooms and the quarters of the business manager. Near the administration building is the large surgical operating house, quite in keeping in its appointments with the most fastidious requirements of the aseptic surgeon. A larger operating room is reserved for aseptic operations, a smaller one for septic cases. The light is excellent, most of the walls consisting of ground-glass windows, the rest of the walls and the floor of glazed white Mettlach tiles. The whole operating room is swung, as it were, in a warm-air bath, for, in addition to heating room proper, warmed air circulates constantly through cavities beneath the floor and between the double walls and windows. The operating house contains also sterilizing rooms, instrument rooms, dressing rooms, nurses' rooms and a microscopic room—quite in accordance with modern American custom. One detail seemed wise—the provision of two currents for the electric lighting of the operating room at night and on dark days—one for regular use, the other in reserve in case of sudden interruption of the regular current in the course of an important operation.

---

* The last article by Dr. Barker, in this series, appeared in THE JOURNAL, Sept. 24, 1904, p. 892.

The main wards of the Nuremberg hospital are, in the interior, very much like those of the Johns Hopkins Hospital in Baltimore, though it must have cost much less to build them. The wards have all the advantages, but also the disadvantages of the pavilion system. With modern ventilating systems, with improved elevator service, and with the newer knowledge of the mode of spread of infectious diseases, the necessity for the pavilion system of construction has largely disappeared; there would seem to be no reason now why the more compact system of hospital building, story above story, should not be returned to. The demands made on medical, nursing and housekeeping staff are enormously reduced in the more compactly built hospital; the administration is, therefore, a much more economical one, and, since hospital administrations are too often more economically inclined than is good for the welfare of the patients, it would seem probable that where endowment is limited the patients will be better cared for, the diseases better studied, other things being equal, in a compactly built hospital than in one arranged in separate pavilions.

The heating, ventilating and lighting systems in the Nuremberg hospital leave nothing to be desired. I was especially interested in the method of disposal of sewage. It seems that a city ordinance prevents the hospital from emptying any unpurified sewage into the city sewers. Accordingly, all the waste water from water-closets, sinks, baths, kitchen and laundry is brought through drains to a special building, where it is clarified and disinfected by the Müller-Nahnsen process. The watery sewage is first mixed with milk of lime, aluminium sulphate and silicic acid, then passed through a sieve to remove larger solid bodies and afterwards led into two large clearing tanks. The latter are about 25 feet deep, the incoming sewage mixing with the contents of the tanks at a level about 15 feet below the surface. Sedimentation takes place in the tanks; the overflow from the first tank fills the second; the overflow from the second is led into the city sewers. The solid bodies held back by the sieve are burned with other garbage in an adjoining crematory. The sediment which collects in the lower part of the tanks is removed from time to time by an electric plunger pump; it is placed in a large filter press, the filtrate running back into the clearing tanks. The residue of solid compressed sediment is carted away and buried; it amounts to about 1.5 cm. (5 cubic feet) a week. The water passing through the clarifying tanks amounts to some 300,000 liters daily. The clearing tanks cost about $8,000 to install; the patent preparation and chalk used to mix with the waste water costs less than $1.00 a day.

Another feature of the Nuremberg hospital which pleased me, one frequently found in sanitariums, but not as often represented in American public hospitals as one would like to see it, is the department for balneotherapy and mechanotherapy. The bathhouse is excellently arranged for hot and cold baths, Turkish and Russian baths, douches, showers, etc.; in addition there are carbonic acid baths, electric tub baths, electric light baths, sand baths, sun baths and mud baths. Nearby are the rooms for gymnastic exercises, massage and apparatus for mechanotherapy

Finally, I must mention among the praiseworthy characteristics of the Nuremberg hospital the number of rooms provided for a single patient, the laboratory for each ward, the excellent Roentgen ray laboratory, the liberal provision of verandas in connection with the wards, the mechanisms for lifting and transporting beds, and the movable iron gratings for the windows of the isolation rooms. The well-organized pathologic laboratory under the direction of Dr. Thorel is also worthy of imitation.

From what I have said it will be obvious that the hospital affords much opportunity for an American visitor to praise; there is but little for him to criticise. He misses, however, the quality of nurse to which he is accustomed at home; there is, further, no nurses' home, for the nurses live in rooms adjoining the wards. Certain hospital features jar on an American's taste, in Nuremberg as in most German hospitals, as for example the permitting of patient's wash basins in the main wards, the conspicuous position given to urinals and bedpans, the unnecessary exposure of patients during clinical examinations, the intimacy of the examining ear with the patient's skin, and the apparent unacquaintance with the utility of towels and screens. But take it all in all, Germany may be very proud of the kind of city hospital of which that in Nuremberg may be chosen as a type.

There is no medical school in Nuremberg, but arrangements are being made by which the hospital and its material will be utilized for the instruction (1) of German medical students during their fifth or hospital-practice year, and (2) of physicians who do postgraduate work in connection with the so-called postgraduate courses (*Fortbildungskursen*) now being organized all over Germany.

Though Nuremberg has had a great industrial awakening, the city authorities and citizens generally are to be congratulated on their efforts to preserve as intact as possible the landmarks of earlier times. In its esthetic characters Nuremberg seemed to me much the same as when I visited it nine years ago. The quaint and picturesque architecture is as interesting as ever, the collections as jealously guarded. You can buy tickets for a lottery of pictures in the Dürer house; the *Gänsemännchen* still steadily holds his double-sided burden in the market behind the Church of Our Lady. Up on Castle Hill the torture-chamber with the "Iron Virgin" excites horror as of yore. The little girl, who, in measured English, used to describe the mysteries of the deep well, is married now, but her account remains to the syllable unaltered. And as we wandered at night through the quaint streets, across the Pegnitz from the Lawrence to the Sebald side and up to the Moritz-Capelle. and again ate sausages and drank black *Tücherbräu* in the little *Bratwurst-Glocklein* we felt that, aside from Rothenburg, there is no place in Germany better suited, perhaps, than Nuremberg to carry one back in spirit to the life and habits of the Germany of old.

(To be continued.)

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer. It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer.]

Eczema in Infants.

The treatment of eczema in infants, according to *Amer. Med.*, consists first in regulating the diet of the mother if she nurses the child. A mixed diet should be prescribed, with prohibition of meat, wine and coffee.

The local treatment consists in removing all dried exudates from the skin by means of a bland oil, followed by a boric acid wash. This should be followed by a soothing application to calm the itching and pain. For this purpose the following combination is recommended:

℞.	Acidi salicylici	gr. i-ii	06-.12
	Zinci oxidi		
	Pulv. amyli, āā	ʒiv	15
	Lanolini		
	Liq. petrolati, āā	ʒiv	15

M. Fiat unguentum. Sig.: Apply locally.

At night the hands of the infant should be tied so that he can not scratch the diseased areas and produce infection.

In chronic cases of eczema occurring in infancy the following combination containing resorcin is recommended:

R.	Zinci oxidi	ʒi	4	
	Resorcini	ʒss	2	
	Ung. aquæ rosæ			
	Liq. petrolati, āā	ʒiv	15	

M. Fiat unguentum. Sig.: To be applied locally.

Ichthyol is also of value combined as follows:

R.	Ichthyolei	ʒiss	6	
	Acidi salicylici	gr. xv	1	
	Adipis benzoinati	ʒvi	24	
	Liq. petrolati	ʒiv	15	

M. Fiat unguentum. Sig.: Apply locally after removing the crusts by means of olive oil.

Resorcin combined with sulphur is very frequently of service in infantile eczema combined as follows:

R.	Resorcin	gr. xv	1	
	Sulphuris loti	ʒss	2	
	Lanolini	ʒiii	12	
	Adipis benzoinati	℥i	30	

M Fiat unguentum. Sig.: Apply locally to the affected areas.

Internally arsenic frequently produces good results when given in the subacute and chronic forms:

R.	Liquoris potassii arsenitis	ʒss	15	

Sig.: Three drops well diluted in water three times a day.

If this preparation disturbs the stomach the liquor sodii arsenatis should be substituted for it, given in the same sized dose.

Where a strumous diathesis is present the following is of value in order to remove the anemia and for its alterative effect:

R.	Syrupi ferri iodidi	ʒiiss	10	
	Syrupi simplicis q. s. ad	℥ii	60	

M. Sig.: One-half a teaspoonful after each meal, well diluted.

Walker, in the *Internat. Med. Annual*, recommends the high-frequency current as producing constant results, especially in the weeping form. He states that the itching sometimes disappears after the first treatment. The peculiar quality of the waves thus produced, according to Regnier, is that they modify the sensibility even to the extent of producing anesthesia without producing any appreciable contraction of the muscle, and is, therefore, useful in local inflammations and in impaired nutrition. Good results have also been reported by many dermatologists in the treatment of eczema by *x*-rays.

Camphor as an Anesthetic.

Leredde, in *Jour. de Med. Interne*, recommends the following combinations containing camphor as local anesthetics in affections of the skin accompanied by itching:

R.	Camphoræ	gr. xv	1	
	Olei amygdalæ dulcis	ʒiiss	10	

M. Fiat unguentum. Sig.: To be applied locally. Or:

R.	Olei camphoratæ	ʒiiss	10	
	Chloralis hydratis	gr. xv	1	
	Liq. petrolati	℥iii	90	

M. Sig.: To be applied locally. Or:

℞.	Zinci oxidi			
	Pulv. cretæ			
	Olei camphoratæ			
	Aquæ calcis, āā	℥i	30	

M. Sig.: Apply locally to the affected areas.

Digestive Infections of Infants.

The general indications for treatment of gastrointestinal infections of infants, according to an abstract in *Archives of Ped.*, are as follows:

IN ACUTE MILD FORMS.

A purgative is given with intestinal lavage and water internally. After twenty-four hours, skimmed milk or buttermilk may be given. If diarrhea is present and persists, bismuth, benzonaphthol and sodium bicarbonate are advised.

IN THE FORM WITH FEVER.

Purgatives, gastric lavage and a water diet are indicated, with compresses on the abdomen, and should be kept up for three or four days.

IN THE ALGID FORM.

In this form purgatives are contraindicated. Lavage with water diet and lactic acid are indicated, together with warm coverings, warm baths, hypodermoclysis and, if necessary, injections of camphorated oil hypodermically, opium and astringents.

DYSENTERIC FORMS.

Sodium sulphate as a laxative, lavage and a water diet are indicated; milk and buttermilk are not, as a rule, of benefit in these forms and are usually not well borne; decoctions of cereals, bread water, toast water, thin chicken broth, farina and at last milk in small quantities serve the best purpose.

CHRONIC FORMS.

A purgative and a water diet are first indicated, followed by a careful regulation of the diet. Alkalies, astringents and antiseptics should be employed, also some of the digestants are recommended such as pepsin and pancreatin.

Bronchial Asthma in Infants and Children.

La Fétra, in *Archives of Ped.*, states that the great majority of the asthmatic attacks are due to bronchial spasm, therefore the treatment should point toward relaxing them. He recommends medication by inhalation as of first importance. In infants where the attacks so closely resemble capillary bronchitis, he recommends steam impregnated with creosote, twenty drops (1.30) to a pint of water boiling in a croup kettle, which in most cases relaxes the spasmodic condition. In older children the niter paper, with or without stramonium, is useful. When the spasm becomes intense and marked dyspnea is present, chloroform inhalations are indicated.

As soon as the infant can swallow, the following may be given to relieve the symptoms:

R.	Antimonii et potass. tartratis	gr. 1/100		0006
	Pulv. ipecacuanhæ	gr. 1/20		003
	Nitroglycerini	gr. 1/100-1/50		0006-.0012

M. Fiat chartula No. i. Sig.: At one dose, to be repeated every half-hour for three doses, or until relief is procured.

[We should hesitate in advising such large doses of nitroglycerin, repeated so often.]

The author has also derived great benefit from the administration of atropin in doses of grain 1/2000 every two hours until the face flushes. A child of 2 or 3 years can take, as a rule, two or three of the above doses before this symptom appears. After the attack has passed off the atropin should be given two or three times a day. If the stomach shows disturbances it should be emptied by a dose of syrup of ipecac. In cases of long standing the following mixture is recommended:

℞.	Potassii iodidi	gr. xx	1	30
	Morph. sulphatis	gr. 1/3		02
	Tinct. belladonnæ	m. xx	1	30
	Spiritus etheris comp	ʒiii	12	
	Aquæ q. s. ad	℥ii	60	

M. Sig.: One teaspoonful every three or four hours.

Falling Hair.

The *Medico-Chir. Jour.* recommends the following combination to check the falling out of the hair:

R.	Acidi salicylici	ʒiii	12	
	Acidi carbolici	ʒi	4	
	Olei ricini	ʒiii	12	
	Spiritus vini rectif. q. s. ad	℥vi	180	

M. Sig.: To be applied freely to the scalp.

The following is recommended by *Merck's Archives* to prevent the hair from falling out:

℞.	Acidi gallici	ʒi	4	
	Tinct. cantharidis	ʒss	2	
	Lanolini			
	Liq. petrolati, āā	℥i	30	

M. Sig.: To be rubbed well into the scalp at night.

Acute Rheumatic Endocarditis.

The treatment of acute endocarditis as a complication of rheumatism consists in the treatment of the cause and of the heart itself to reduce its increased activity and excitability which necessarily tend to increase the inflammatory condition of the valves.

In the treatment of the cause the patient must be put to bed and quiet instituted. The diet should consist principally of milk. The alkalies should be given in sufficiently large doses to promote elimination and to alkalinize the urine. Water should be given freely with the alkalies, such as potassium bicarbonate or citrate. Alternating with the alkalies or combined with them, sodium salicylate should be given in rather large doses. Salicin in doses ranging from grains five to ten (.30-.65) may be substituted for the salicylates.

As to the heart itself, it should do the least amount of work possible. Its action may be controlled by complete rest in bed, ice-bag to the precordial region or in some cases heat applied to the precordium. When much pain is present over this region small doses of codein or of Dover's powder should be given. When the heart becomes rapid or irregular, small doses of strychnia or alcohol are indicated. Anemia not infrequently is present in a good per cent. of these cases occurring in early adult life, and should be corrected as rapidly as possible along with the essential prolonged rest in bed. When the rheumatism has disappeared and the temperature has dropped to normal the patient may be placed on a combined tonic and alterative treatment, and for this purpose the syrup of ferri iodidum is recommended in moderate doses to correct the anemia and changes in the valves as well as in the blood vessels. Arsenic combined with iron and strychnia is a splendid combination during convalescence, as follows:

℞ Acidi arsenosi	gr. 2/3		04
Strychnin. sulph	gr. ss		03
Ferri sulph.			
Sodii carb., āā	.3i	4	

M. Fiant cap. No. xxx. Sig.: One after each meal three times a day.

Epidemic Cerebrospinal Meningitis.

The treatment of epidemic cerebrospinal meningitis, according to W. J. Wilson in *Jour. Mich. State Med. Soc.*, consists in sustaining life by rectal feeding of peptonized milk with yolk of egg when gastric irritability is present and a tendency to vomit. Lavage should be resorted to and light nutritious food given, such as whey, white of egg, broths and soups, administered at intervals of three or four hours. The sick room should be kept at a temperature of from 68 to 70 degrees F. If marked fever is present, the scalp should be shaved and an ice-cap applied to the top of the head and a bag to the nape of the neck. A mustard footbath is recommended by the author in some cases to relieve the cerebral symptoms. Special attention must be paid to the bowels and kidneys, and if the urine is scanty, high colonic flushings of a normal salt solution should be given at a temperature of 110 degrees F. When active delirium is present hyoscyamin should be given hypodermically in 1/100 grain (.0006) doses.

Suppositories each containing chloralamid grains ten (.65) with or without small doses of belladonna are of benefit to produce sleep.

Large doses of potassium iodid or of sodium iodid in daily doses of from fifteen to sixty grains (1.-4.) should be tried. Mercurial ointment rubbed into the scalp and nape of the neck, morning and night, may be of service.

Medicolegal.

How to Recover Money Paid Illegal Practitioner.—The Court of Civil Appeals of Texas says, in the case of Gaither vs. Lindsey, an action on a contract for the treatment of the defendant's wife, that, in order to recover money already paid for the treatment of his wife, the defendant would have to do more than to prove that the plaintiff was practicing medicine in violation of the law. Unless, in addition, the defendant could show that he was deceived and imposed on, he would not be entitled to recover back money already paid, although the plaintiff could not recover anything from him, since the general rule would apply that money voluntarily paid cannot be recovered. If, however, the plaintiff in any way represented himself to be a practicing physician, when he was not authorized to practice medicine, and the defendant was thereby induced to employ and pay him for professional services, he could recover the money so paid.

May Give Conclusions Without Facts.—The Supreme Court of Iowa says that, in the case of Morrow vs. the National Masonic Accident Association, the only witnesses examined by the association as experts were physicians who had either attended the insured in a professional capacity after his injury or were present and took part in the postmortem examination held. Yet before they were permitted to testify their conclusions as to the cause of death they were required to detail all of the facts on which such conclusions were based. These rulings were, in the judgment of the Supreme court, clearly erroneous, because every conclusion testified to was based on actual knowledge of the physical condition of the deceased, and, further, because the rule has never, to the knowledge of this court, been applied to witnesses who were in fact experts on which they were called to testify. But, notwithstanding the error in the rulings, it must be held that they were without prejudice, because of the fact that in every instance the testimony was made competent under the rule of the district court and the conclusions of the witnesses received. Again, the Supreme Court holds that if there had been no conflict on the question of the cause of death the jury would have had no right to disregard the evidence of the physicians and find independently of it. But when there is a conflict in the evidence on a given point it is the general rule that the jury is not bound to treat the testimony of any witness as conclusive, no matter whether he be an expert or a non-expert.

Unlawful Practitioners—Taxing Itinerant Physicians.—The Supreme Court of Iowa says that the charge in the case of State vs. Edmunds was that the defendant, being a nonresident, assumed the duties of, and publicly professed to be, a physician, and did attempt and profess to heal and cure diseases by dieting his patients and causing them to take certain exercises and to wear glasses furnished by him; that he went about and in various ways solicited persons to meet him for treatment, and did, while so practicing as an itinerant physician, treat and attempt to cure injuries, diseases, etc. Did the acts charged constitute an offense under the laws of Iowa? Section 2579 of the Code defines "physician," "practice of medicine," etc., as follows: "Any person shall be held as practicing medicine, surgery or obstetrics or to be a physician within the meaning of this chapter who shall publicly profess to be a physician, surgeon or obstetrician, and assume the duties, or who shall make a practice of prescribing or prescribing and furnishing medicine for the sick, or who shall publicly profess to cure or heal." Section 2,580 provides a penalty to be imposed on "any person who shall practice medicine, surgery or obstetrics in the state without first having obtained and filed for record the certificate therein required." Section 2581 defines an "itinerant physician" as follows: "Every physician practicing medicine, surgery or obstetrics, or professing or attempting to treat, cure or heal diseases, ailments or injuries, by any medicine, appliance or method, who goes from place to place, shall be considered an itinerant physician." This section also provides for a license fee of $250 per annum, the same being payable into the state treasury for the use of the state of Iowa. Such license may issue only to such as hold a certificate from the State Board of Medical Examiners. It was contended that as the defendant did not profess or attempt to cure by any medicine, appliance, or method similar to medicine, but by dieting his patients, etc., his acts did not come within the prohibitions of section 2581. The Supreme Court says that the question here was a narrow one, depending wholly on the construction to be given the words "medicine, appliance, or method." Do they mean a medicine or drug, or something administered as a medicine or drug would be? The court thinks this too narrow a construction. It says that an appliance can hardly be said to be a medicine or drug, and a method may or may not involve the administration of any substance, either internally or externally. True, when general terms follow specific words of a like nature, the general terms are presumed to embrace things and methods of the kind designated by the specific words. But for this rule to apply, it must appear that the general words are of a like nature. This was not true here. Undoubtedly the state has the right to determine what acts shall constitute the practice of the healing art, and it may impose conditions on the exercise of that privilege. Having defined the terms it uses, courts should accept the definition given, and not be too subtle in the use of refined distinctions. To save its people from quacks and charlatans, the state has plenary power to prohibit or supervise the exercise of the healing art. Statutes similar to the one in question have been enacted in many states, and they have been held to apply to magnetic healers (State vs. Parks [Ind. Sup.], 59 L. R. A. 190, with notes and briefs); empirics (Musser vs. Chance, 29 Ohio St. 577; Nelson vs. State Ky., 57 S. W. 501); obstetricians (State vs. Welch, 129 N. C. 579); midwives (People vs. Arendt, 60 Ill. App. 89); Christian scientists and osteopaths, although there is a decided conflict in the authorities as to these two classes of healing (Little vs. State, 60 Neb. 749; People vs. Jones, 92 Ill. App. 445; State vs. Buswell, 40 Neb. 158; contra, State vs. Myloid, 20 R. I. 632); and itinerant practitioners (State vs. Blair, 92 Iowa 28). See also State vs. Heath. 101 N W. 429 (reported in THE JOURNAL Jan. 7, 1905). Cases from other states cited and relied on by the defendant's counsel were not in point, for the reason that the statutes therein construed were not so broad as the one here before the court. The Iowa legislature evidently intended to prohibit the practice of the healing art by the use of medicine or any kind of appliance or methods, except on certain named conditions. The language used is very broad and comprehensive, and covers any and every kind of public profession to cure and heal by the use of any method or device. It confines the practice of medicine to the school or schools regarded as lawful, and does not permit quacks and charlatans to impose on the public. The charge against the defendant was that he was practicing as an itinerant physician without the required license, and it was unimportant, the court says, to inquire as to whether or not he had a state certificate, as this would afford him no protection. There may be some doubt as to whether a non-resident may obtain this certificate, maintain his residence in another state, and practice his profession in Iowa without obtaining the additional license required by section 2581 of the Code. But as to this the court expresses no decided opinion at this time. As to the contention that the license tax is unreasonably high, oppressive, and prohibitive, the court says that, being in the nature of an occupation tax, the state undoubtedly had the right to fix it at such sum as it saw fit. While the practice of medicine is often spoken of as a right, it is not, strictly speaking, a right, but a mere privilege, upon the exercise of which the state may impose conditions such as it deems advisable. The title of the act is, "Of the practice of medicine," and, the court says, the subject-matter is sufficiently expressed. It was error to sustain a demurrer to the indictment.

December 31.

1 *Ideal Method of Removing the Vermiform Appendix. H. A. Kelly, Baltimore.
2 Tuberculosis of the Kidney, Ureter and Bladder. J. M. Baldy and Ed. A. Schumann, Philadelphia.
3 Primary Sarcoma of the Stomach: A Report of Three Cases. John A. Sipher, Cleveland.
4 The Reflexes in the Diagnosis of Nerve Lesions Due to Trauma. Henry S. Upson, Cleveland.
5 *The Cause of Death in Cases Operated on of Intestinal Perforation Occurring in Typhoid Fever. J. H. Anderson, Pittsburg.
6 Polyneuritis Complicating Typhoid Fever with Unusual Localization. Alfred Gordon, Philadelphia.

1. **Ideal Appendicectomy Method.**—With a view to devising a method for removing the vermiform appendix which will overcome the difficulties of all methods now in vogue, Kelly has made a pair of crushing forceps with longitudinal grooves on the crushing surface and a bevel above. When this forceps is applied, it requires a force of from 25 to 40 pounds to lock the blades on the appendix, and a force of about 60 pounds to release them after the appendix has been cauterized. The only other special instrument required is the ordinary Paquelin cautery. The method of operation is as follows: The appendix is exposed and the mesoappendix is tied off. A circular suture of fine silk is then laid around its base, about a centimeter distant, but not drawn up. The appendix is then grasped at its base with the forceps and crushed, while just beyond the forceps (distally) it is seized with an ordinary artery forceps to prevent the escape of its contents. Paquelin's cautery is then used to amputate the appendix between the two forceps, when it is laid aside in the grasp of the artery forceps. The crushing forceps, which is to be converted into a cooking, sterilizing, sealing iron, is carefully isolated by tucking dry gauze under each blade, so as to lift the end of the forceps up on a cone, away from all contact with the cecum. The next step, which is the most important one, is to keep the red-hot point of the cautery slowly traveling up and down the groove in the crushing forceps for from 40 to 60 seconds, so as to burn off every vestige of the stump, and at the same time to heat the forceps so thoroughly that the narrow ribbon of crushed appendix in its grasp becomes converted into a translucent, gristle-like substance in which the lumen of the appendix is completely destroyed. The lumen is so effectually obliterated that it never gaps. The final step in the operation is the tightening of the purse-string suture, and the inversion of the cooked base, after which the serosa is carefully united over the whole with another row of fine silk sutures. Kelly has cut off a little piece of the cooked tissue in seven cases and dropped it into a test tube containing agar medium, and in but one case was any growth obtained. The advantages he claims for this method are: Its perfect simplicity. There is at no time any exposure of the infected mucosa, the stump is not ligated or bruised, and thus left as a culture medium for whatever organisms may have lain in it. The appendix is amputated with the cautery and the proximal portion is sterilized and effectively sealed. The inverting sutures are then applied over an area as free from contamination as the rest of the peritoneal cavity.

5. Cause of Death in Typhoid Perforation.—Anderson reports his experiences in 21 cases of laparotomy for intestinal perforation. Twelve patients were operated on within 36 hours after the onset of the symptoms. Of these 9 were for perforation and 3 patients recovered. The remaining 3 cases presented symptoms resembling perforation; 1 case was typhoid appendicitis with peritonitis, 1 of peritonitis from mesenteric lymph gland infection, 1 of obstruction due to round worms in the ileum. These 3 cases recovered, making a total of 50 per cent. of recoveries in these 12 cases. The remaining 9 patients were operated on at varying periods of from two to four days after perforation; all died. Local anesthesia was used in 8 cases, the patients being extremely weak and toxic, and all died. In 9 cases the fecal contents of the ileum were removed through the perforation or by incisions. Four patients recovered; 3 were operated on for perforation and 1 for peritonitis from lymph gland infection. The peritoneum was irrigated with normal salt solution in all cases, with special attention to the diaphragmatic peritoneum. In these 9 cases there was a decided amelioration of the postoperative symptoms, which

leads Anderson to believe that irrigation of the bowel is of importance in preventing the toxemia which results from the absorption of poisons from the contents of the paralyzed bowel. He holds that toxemia is quite as important as peritonitis and insists on the institution of drainage.

7 *Effect of Hysterectomy on the Sexual Function. H. N. Vineberg, New York.
8 Difficulties of Anesthetization and Their Correction. Victor C. Pedersen, New York.
9 Hyperacute Melancholia: Case. R. N. Todd, Indianapolis.
10 *The Finsen Method. Milton Franklin, New York.
11 *Antiseptic Treatment of the Puerperal Woman. L. Kolipinski, Washington, D. C.
12 Cerebral Palsies in Children. J. M. Aikin, Omaha.

7. **Hysterectomy and the Sexual Function.**—The conclusion Vineberg draws from his own experience and from his study of the literature on the subject is that whatever other effects the removal of the uterus and ovaries may have on the female economy, it has little or none on her sexual feelings.

10. **The Finsen Method.**—Franklin describes the development of the Finsen method of treating tuberculous diseases of the skin by exposure to the ultra-violet or chemical rays of the spectrum. The description of the apparatus used is complete and doubtless will be of considerable assistance to those who employ this method. Franklin is of the opinion that the Finsen method, when properly practiced, and this necessitates the employment of suitable apparatus, free from glass and of sufficient power, is superior to all known procedures for the treatment of lupus vulgaris. This opinion is the result of close observation of the results obtained at the only place where the method has been properly employed. He says the use of the *x*-ray has been too limited to warrant the positive assertion that it is a specific in lupus. The cases that have been positively cured by the Finsen method are almost without number, while those cured by the *x*-ray are few and scattered and their authenticity shrouded in uncertainty.

11. **Antisepsis in the Puerperium.**—A word is said in favor of irrigation after delivery by Kolipinski, who considers the woman delivered of the new-born child a surgical subject, the victim of wounds of the contused and lacerated varieties, of the uterine cervix, the vagina and its outlet, injuries which, when not protected by art, are the chief cause of puerperal infection. A superficial torn wound of this or of any other part of the body, says Kolipinski, requires surgical treatment which is both curative and preventive. One of the best in thoroughness and efficiency is irrigation, and douching is one form of irrigation. He has used antiseptic douching in normal puerperal cases, and the effects are found to be in every way satisfactory, both in the feeling of general comfort to the patient and in the avoidance of septic fever, or its speedy destruction. He has followed the rule that it is better to flush with too much rather than with too little, and accordingly his method consists in washing out the vagina, the cervix and the vulva, the patient being in the proper position, with a gallon of a solution of boric acid in boiled tepid water, one and one-half drams of powdered acid to the pint. This is repeated three times a day for the first week and then discontinued altogether. The antiseptic vulvar pad is dispensed with or its use left to the discretion or wish of the nurse or patient. Septic fever has not been found to appear in any of the author's normal cases, and the patients have all been well satisfied with the result.

New York Medical Journal.

13 *The Value of Stereoscopic Skiagraphy. M. K. Kassabian, Philadelphia.
14 Rôle of the Thyroid Gland in Exophthalmic Goiter Associated with Paralysis Agitans. Alfred Gordon, Philadelphia.
15 *Cysts of the Mesentery: a Case. L. S. McMurtry, Louisville.
16 Surgical Diseases of the Sigmoid. H. D. Niles, Salt Lake City.
17 *Enuresis and Its Treatment. J. Ullman, Buffalo.
18 *Unusual Case of Friedreich's Ataxia. R. N. Van Wart, New Orleans.

13. **Stereoscopic Skiagraphy.**—Kassabian details the principles of this method, the technic for making the skiagrams and the methods of examination of stereoskiagrams. The method is useful for demonstrating the structure of bones, studying the mechanism of joints, localizing foreign bodies and diagnosing fractures, showing the exact position of the fragments, the amount of overlapping or separation, the degree of apposition in deformities, etc. Although the method requires more time and care than ordinary skiagraphy, the results obtained with it compensate for these seeming disadvantages.

15. **Cysts of the Mesentery.**—The case reported by McMurtry was one of sero-sanguinous cyst of the mesentery, arising in the colonic mesentery near the left kidney in a woman, aged 67, who complained of digestive disturbances. The displacement of the colon by the tumor was such that the bowel seemed to enter and emerge from the tumor. The cyst wall was quite thin from distention. The left fallopian tube was attached to the tumor and bled freely when separated. There was no pedicle proper to the tumor, which evidently originated and developed between the folds of the mesentry. The area of enucleation was drained through the lower angle of the abdominal incision, and the abdomen closed in the usual way. The patient made a perfect recovery.

17. **Treatment of Enuresis.**—Ullman says that a solution of atropin, 1 grain to 2 ounces of water, 5 drops to be given at 4, 7 and 10 p. m., together with certain movements and hygienic and suggestive methods to which he refers, will usually give excellent results in the treatment of purely neurotic cases. The movements referred to are as follows: 1. The rectum is freed of feces and massage is applied to the sphincter vesicæ by means of the index finger. The child lies in the lithotomy position and, with the index finger in the rectum, the sphincter vesicæ is gently tapped for from one-half to one minute. 2. A deep circular massage is applied over the hypogastric region for from two to three minutes. 3. The patient, lying in the dorsal position, with the knees tightly drawn together, is told to resist while the knees are drawn apart, and, with the knees widely separated, he is asked to resist while they are drawn together. The same resistant adduction and abduction movements are carried out with the legs. These movements occupy about two minutes. 4. The patient, standing against a wall or door, crosses and recrosses one thigh over the other for a period of five minutes. 5. The patient is next taken across the knee and with the side of the hand the lumbar and sacral regions are sharply tapped very frequently, thus giving a vibratory sensation.

18. **Friedreich's Ataxia.**—This unusual case is presented by Van Wart to show that cases of hereditary ataxia are not necessarily doomed to chronic invalidism. His patient, an adult male, 44 years of age, traced his illness back to the sixth year of life. While never able to perform any heavy work, he could plow, drive and do most of the lighter work about the farm. When 30 years of age he became so disabled that he had to use crutches, and he then became a school teacher, following this occupation until two years ago, when the increasing ataxia in his hands compelled him to abandon this work also. His general condition was good.

21½ Trachoma. Albert C. Bardes, New York.
22 Present Attitude Toward the Treatment of Prostatic Hypertrophy. Martin W. Ware, New York.

20. **Gastric Ulcer.**—Robinson considers this subject as it presents itself to the physician and to the surgeon. The cases in which a surgical operation is most likely to effect a cure that it places the knot between the apposed peritoneal sur-

are those of acute ulcer in which hemorrhage occurs suddenly, is profuse, repeated, and the outcome too eminently fatal to permit of the use of medicinal agents or hygiene and time, or those of chronic ulcer, in which the frequent and profuse hemorrhage may be taken as an indication that the degenerated gaping artery of the diseased surface may be obstructed for a while with a clot but will soon, through its removal, bleed afresh. An operation affords the only assurance of a cure. The same is true when perforation of the stomach has occurred, complicating any form of ulcer The sooner the operation is performed the greater the chances of saving life. Although instances of cure without operation are recorded, they are very infrequent, and unless special conditions prevail, such as an empty stomach, very small opening on the ulcer in the stomach, chronic adhesions to adjacent organs, etc., even these instances would not have been possible. Robinson's attitude toward the surgical treatment of gastric ulcer is rather conservative, for as yet the results obtained from operative treatment are inferior to those obtained by proper medical care, especially in cases occurring among patients in affluent circumstances who seek medical advice early and who can carry out with intelligence the necessary dietary and remedial regimen. Hemorrhages in such cases are infrequent and slight and perforations occur rarely. Robinson's treatment is that of others who have given this subject considerable attention One food which he mentions as being of special value when hydrochloric acid is deficient in the stomach is buttermilk, freshly made, and freely taken. He says that in several cases its use appears to have been followed by a permanent cure In the treatment of the accompanying anemia he prefers to make use of the vegetable forms of iron rather than the mineral, which may be more or less irritating locally by their acidity and perhaps slightly corrosive action.

21. The "Yolk Cure" of the Underfed.—Stern again calls attention to the fact that underweight and underfed are not synonymous conceptions; that an individual of underweight but in metabolic equilibrium is not underfed, and that in the real underfed there is always a traceable disease or disorder which, directly or mediately, prevents normal digestion or complete utilization of food stuffs, giving rise thereby to bodily decline. It is absolutely useless to attempt to check bodily decline by forced feeding without paying attention to the condition of the digestive organs and the general assimilatory qualities. As soon as the organism is able physiologically to dispose of the ingesta, the tide of body decay is stemmed in all those instances in which some digestive assimilative disturbance, directly or remotely, stood at the foundation of the malnutrition The treatment of the so-called wasting diseases resolves itself into the prevention of waste. The most potent factor in maintaining physiologic digestion and assimilation is an adequate food supply, one which is sufficient as regards quantity and which the organism is able to anabolize. Stern believes that the diet which he has termed the "yolk cure," one in which the greater portion of the calories yielded and in which the egg yolk forms the only fatty substance, is ideal in these conditions This yolk cure may be modified as needed. The yolk of the hen's egg in the raw or half raw state is digested readily, is well borne, contains a diastatic ferment, does not exhibit fermenting qualities, stimulates gastric secretion, restores nerve force and also contains lecithin. From eight to twenty calories a day and kilogram of body weight are necessary to overcome the condition of underfed. An average yolk contains between five and six grams of fat, representing about fifty calories. The author gives explicit instructions for carrying on this particular dietary and gives a sample menu destined for a consumptive whose alimentary system admits the ingestion of some carbohydrates and of almost normal amounts of proteids.

27 Isolation Methods and Precautions in Contagious Disease F. P. Denny, Brookline, Mass.
28 Suspected Homicide Proved to Be Suicide by Strychnia. F. J. Canedy, Shelburne Falls, Mass.

23. Cauterization of Lower Turbinate.—The object of Goodale's paper is to give the results of a histologic examination made into a series of cases which had been previously cauterized for swelling or hypertrophy of the lower turbinates and which had reported later with a recurrence of nasal obstruction. Goodale found that caustic applications to the nasal mucous membrane may cause a loss of the columnar ciliated epithelium with a replacement of this by cells of squamous type. That immediately below the cauterized mucous membrane new connective tissue may be formed, which extends downward to a depth dependent on the intensity of the trauma. That the contraction of the tissues following caustic applications is due to the contraction of this new form of connective tissue, and the consequent compression both of the lymph sinuses and of such cavities as the lumina of blood vessels and glands. That repeated superficial applications of caustics tend to the formation of connective tissue immediately beneath the epithelium, which by its contraction may constrict the lumen of the ducts of the glands and lead to cystic dilatation of the latter, thus contributing to a subsequent return of the nasal obstruction. As to the proper mode of cauterizing: If it is desired to contract a relaxed or distended mucous membrane, we should endeavor to reach its deeper layers where the lymph spaces and blood vessels are situated, producing at the same time a minimum amount of disturbance to the membrane itself. This result is best attained by deep linear applications, as narrow as possible, of chromic acid, or of the galvanocautery, or by submucous cauterization. If it is simply desired to diminish the nasal fluid we may advantageously sacrifice a certain number of canaliculi in the basement membrane by broad, superficial applications to a definite area of the septum and lower turbinates posteriorly. In the event of recurrence of the enlargement after cauterization, it is preferable to dispense with further cauterizing and to proceed immediately to the excision of a definite amount of obstructive tissue.

25. Improved Method of Intestinal Anastomosis.—This is the first of a series of four papers to be published by Gould illustrating changes in technic. The first paper describes an improved method of end-to-lateral intestinal anastomosis. The open intestine is split along its free border for about one and a half inches, and the corners, which project, are trimmed down with scissors so that an oblique opening is left with edges rounded out at the mesenteric border, thus allowing more tissue for sewing. The receiving intestine is opened on its free edge for about two inches, and the distal end of this cut is fastened by a mattress stitch to the mesenteric border of the entering bowel. Guides are placed, with the ends left inside, in such a way that they will invert the cut edges and expose the mesenteric third of the entering bowel side by side with a symmetrical portion of the cut edges of the receiving bowel. On tightening the guides, the remainder of the circumference falls away and allows easy introduction of the first layer of stitches. This layer is a continuous over-and-over No. 0 chromic stitch which starts from one guide and goes directly across to the other, piercing all coats. When the second guide is reached other guides are placed on the sides at regular intervals to assist in accurately matching the cut edges. When the free ends of the dorsal cuts are reached they are altered to make them fit one another, and the suture continued around to the opposite side, where it is tied to the long end left at the beginning of the stitch. The second step is the introduction of an interrupted sero-muscular stitch. Gould has modified the mattress stitch by placing the loop near the cut edge. This rolls the protruding edges down and approximates the peritoneum without the necessity of tucking in. This change might be applied to both sides of the stitch except for the objection faces. The details of this operation which Gould considers original are: 1. The method of trimming the invaginating gut. 2. The method of placing the first layer of stitches. 3. The new mattress stitch.

36 Protozoan of Scarlet Fever; Preliminary Report. Charles W. Duval, Philadelphia.

33. **Congenital Absence of Tibia.**—From a careful examination of cases under his observation, and from a thorough investigation of the literature on the subject, Young is of the opinion that congenital absence of the tibia is due to an injury received in the early months of fetal life, usually about the third month. The cases presented by him would seem to prove that a sudden and a violent pressure on the uterus which would be sufficient to cause inflammation of the soft parts, but not of sufficient force to injure or fracture the bones, would lead to an amniotitis followed by hydramnios which would produce the exact conditions found in these deformities.

34. **Retrodisplacement of Uterus.**—Beyea's article includes the report of a statistical study of 465 cases of retrodisplacement of the uterus operated on by a method of ventrosuspension of the uterus, abdominal primary fixation of the fundus uteri to the anterior abdominal wall, and secondary to ligamentary suspension. The author has used this method for eleven years in 465 cases and it has always proved an efficient operation, has never been complicated, and never produced abnormal gestation nor complicated labor. In order to obtain these results it is necessary to secure the uterus to the anterior abdominal parietes, forward, in an exaggerated normal position, so that in the succeeding weeks, through the mobility of the organ, its traction on the abdominal walls, with, for instance, distension of the bladder, and through change in tension of the abdominal walls, a ligament is formed or pulled out to maintain the uterus in about its normal position, until the pathologic changes described disappear and the normal conditions of uterine support are restored. This ligament must be of just sufficient strength to maintain the uterus forward as a guy rope; must not be attached to nor involve a wide surface of the uterine parenchyma, and the tissue forming the ligament must be of such a character as to undergo hypertrophy or stretching during the growth of the uterus in gestation. Beyea addressed inquiries to the 465 women operated on in the past eleven years and received replies from 272. Of this number, 231, 85 per cent., say that they have been completely relieved and enjoy excellent health; 28, 10.5 per cent., state that they have been benefited, the greater part of the symptoms having been relieved; 13, 4.5 per cent., assert they have received no benefit. The improvement has been lasting in 225. Backache was completely relieved in 215; benefited in 39, and not improved in 17 cases. Headache was completely relieved in 228; benefited in 32, and not improved in 12. Nervousness was completely relieved in 189. The question as to the gain in weight is interesting. There were 63 who failed to take on flesh, and 9 have lost in weight. The remainder all gained between 2 and 40 pounds in weight. As to the time when improvement began, 55 stated that improvement began immediately or very soon after they reached home; 72 began to improve in from one to five months after the operation; 58 in from six to eleven months; 26 did not receive full benefit until a year had passed; 4 for eighteen months and 4 for two years. Beyea has personal knowledge of 5 recurrences of the displacement. In 3 it occurred before the patients left the hospital, in 2, as a result of pneumonia, the coughing causing such a strain on the abdominal walls as to sever the attachment, and in the other the attachment was separated by the resident physician in removing the sutures from the cervix. Another woman, regardless of advice, did heavy lifting immediately after returning home, and the retrodisplacement recurred. In the other case the uterus was retroverted and on opening the abdomen again the ligament was seen attached to the anterior surface of the uterus well below the fundus. Of the 272 women, 153 are married, and of these, 41 have been pregnant since operation; 37 have gone to term and borne a living child; 5 have twice borne a child, 2 having given birth to twins; 1 twice. In none of the 47 labors was there a complication which could be attributed to the operation. Nine of the 153 women have aborted or miscarried, 5 twice, all before the sixth month. There was one death, which occurred eighteen hours after a cervical dilatation and ventrosuspension of the uterus, the operation lasting 30 minutes. The postmortem failed to reveal the cause of death, and the conclusion was that death resulted from surgical shock, for there was a rapid failing heart action. This makes the mortality a little less than .2 of 1 per cent.

37. **Experiments with Radium.**—Beck reports his results accruing from the use of radium in the treatment of nose, throat and ear diseases. In a case of primary tuberculosis of the septum, 33 applications of radium bromid were made, each lasting from five minutes to half an hour, given at first every day, later three times a week and finally once a week. The headaches and pains disappeared after the second treatment. After about six treatments the mass looked better and did not bleed so easily on touch. After twelve treatments the patient was able to breathe better, and since then there has been a continued improvement and a diminution in the size of the growth. A case of nasal syphilis was treated intranasally with the result that there was relief from pain and a correction of the odor. In a case of sarcoma of the nose, the radium gave relief from pain and produced sleep, saying nothing of the possibility of the prevention of the recurrence of the malignant growth. Very satisfactory results were also obtained in a case of sycosis. A case of lingua nigra was cured by seven exposures. In a case of secondary tubercular laryngitis the radium failed to give any relief, as also in a case of carcinoma of the larynx with glandular involvement. In a case of chronic suppuration of the middle ear with necrosis, the odor was markedly modified and the discharge lessened. Pains in the ear were less marked. In a number of other painful conditions Beck has found the radium to afford more or less relief from the pain.

38. **Pus Infection Simulating Tuberculosis.**—The first case related by Babcock presented all the constitutional symptoms of pulmonary tuberculosis, but the lungs, though not normal, did not furnish any signs of disease. A thorough examination led Babcock to the belief that it was a case of septicemia originating in a pelvic peritonitis with purulent and circumscribed exudate, and that the indefinite lung find-

ings were due to some pulmonary change resulting from the infection and feeble cardiac action. This belief was confirmed at the operation. The second case was one of suppurative peritonitis due to trauma. The lung findings were very similar to those described in the first case. Three other cases were ambulatory and sought medical advice because of symptoms which they feared were due to an incipient pulmonary tuberculosis. One of these cases was found to be a suppurative appendicitis; a second was a case of cholecystitis, and a third a case of pyosalpinx.

41. **Correction of Septum Deformities.**—Robertson divides his cases into four groups: First, those which may be considered deviations of slight degree. A great majority of these may be treated by the removal of the excess of mucous membrane, cartilage or bone at the apex of curvature. Second, cases where the removal of the apex of the deflection will not suffice. In this class of cases some operation, such as the removal of v-shaped sections or a flap operation, is necessary to render the nostrils patulous. Third, cases which present irregular masses, marked deviations, and probably deep grooves or clefts on the side of the concavity. A window resection is the indicated operation. Fourth, cases in which from internal and violent injury the nasal bones are dislocated or fractured, and the septum is wrinkled or broken, causing obstruction by deflection to one or both sides. In this class of cases an external operation is advised. Speaking of the different forms of operative procedure, Robertson says that the sawing off of a ledge or spur will often give more room than would appear possible at the pre-operative examination. Great care in saving mucous membrane in these cases is not so important as is usually believed, as it is generally hypertrophied and, therefore, a diseased tissue. The precaution of avoiding a perforation is essential. The author comments on the impracticability of v-shaped operations, as made by files and knives, on small deviations, the consequent packing into space until the septum has regained its rigidity. Crushing operations are usually failures; they are brutal and unsurgical, and impracticable because it is impossible to make the circumference of an arc fit into a space the length of a segment of the arc. In most cases where there is no external deformity the Gleason method is the best; packing is necessary for only a short time. It is essential to save all tissue that is not diseased and is still functionating. He also comments on the absence of firm cartilaginous support in the window resection operation, and the liability of one or more perforations occurring duriing operation or healing.

46. **Multiple Primary Carcinoma.**—Bunting reports two cases. The first, male, aged 52, died from cardiac disease and at the autopsy there were found in the middle portion of the ileum six nodules scattered over a length of intestine of about 50 cm. These nodules varied slightly in size and were situated beneath an intact epithelial surface. They were of a definitely carcinomatous structure, apparently taking their origin from the epithelium of the crypts of Lieberkuehn. There were no metastases in any other organs. The evidence at hand is reviewed to show that all these nodules were primary. The second patient, male, aged 59, was taken ill with symptoms referable to intestinal obstruction and a palpable mass in the right iliac fossa. Exploratory operation revealed an inoperable carcinoma in the cecal region and a second mass in the sigmoid flexure. Carcinomatous tumors were found in the ileum, cecum and sigmoid. They were of the cylindrical-celled adeno-carcinomatous type, with ulcerated surfaces, without involvement of the peritoneum, and without metastases in other organs.

60½ Gunshot Wound of the Abdomen Involving the Hip Joint; Report of a Case, with Remarks. L. H. Laidley, St. Louis.

50. **Cancer of the Cervix Uteri.**—After a thorough consideration of this subject, Balloch concludes that the present status of operative intervention in cancer of the cervix uteri is that it is practically useless in cases as they usually come under the notice of the surgeon. In the operable cases the only procedure offering any reasonable prospect of a permanent cure is the so-called radical operation by the abdominal route. Vaginal hysterectomy is useless as a radical operation, but has a place as a palliative measure. Balloch urges that the upper part of the vagina is deserving of more attention, from the standpoint of recurrence, than it has heretofore received. The most promising outlook for these cases, he continues, lies in early diagnosis, combined with thorough and complete operative measures. The starvation of the disease by cutting off its blood supply is a palliative measure worthy of trial.

52. **Streptococci in Air.**—Rosenow made some careful observations to explain the probable source of certain accidental, postoperative, peritoneal infections and calls attention to the following facts: 1. The infections occurred only in the most extensive, prolonged, intraperitoneal operations. 2. Owing to the large number of operations, the operating rooms were often in use from morning until night. These rooms were seldom disinfected. 3. The accidents occurred during the winter months; no adequate system of ventilation was in vogue anywhere in the institution. 4. During this time a number of patients suffering from very severe streptococcus infections were being dressed in the general dressing rooms of the hospital. The same carts on which these patients were dressed were used in transporting other patients to the operating room. 5. An epidemic of streptococcus angina prevailed among internes, nurses, attendants and patients. 6. The streptococcus pyogenes was responsible in each instance. Rosenow is convinced that there is what might be called "hospital air," which, under circumstances such as those mentioned, may become rich in pathogenic bacteria. The streptococcus seems to become more virulent or more numerous during an epidemic of angina due to this cause. Rosenow advises that persons suffering from such an affection should be isolated, and that the operator, the assistant and all connected in the handling of surgical material before and during the operation should wear a proper mouth covering. All sterile surgical material should be exposed to the air as little as possible. All operating rooms should be frequently fumigated with an efficient disinfectant.

70 The Therapeutic Uses of Hamamelis Virginica. H. R. Coston, Birmingham, Ala.

67. **Treatment of Erysipelas.**—Davis details his experiences with antistreptococcic serum in the treatment of erysipelas. As the site of injection he prefers the anterior portion of the thigh, about midway between the knee and hip joint, in the body of the quadriceps extensor muscle. The amount of serum to be used will vary in each case. He usually begins by giving 10 c.c. and repeating the dose as often as is necessary. Twenty c.c. may be given at the beginning if needed. It is essential to give enough. His results from its use have been uniformly satisfactory.

68. **Adrenalin Chlorid in Typhoid Hemorrhages.**—Thrush has had an extensive experience in the use of adrenalin chlorid in the treatment of hemorrhage complicating typhoid and considers it superior to other astringents. The drug is particularly valuable in that it is also a decided vascular stimulant, stimulating the heart directly, and by contracting the arterioles it raises arterial tension. He gives 20 mm. doses (1 to 1,000) hypodermically every three hours until the hemorrhage is entirely controlled, when it can be administered per os in 10 mm. doses for the next 24 hours. The usual methods of applying ice to the abdomen, the elevation of the foot of the bed, etc., are recommended as valuable adjuncts in the treatment.

74 Organization and Work of the Maritime Quarantine Service of the Isthmian Canal Commission. Henry R. Carter.

73. **Radical Cure of Varicocele.**—Aguirre describes a new method which consists in employing at the same time transverse resection of the scrotum and the excision of the bundle of varicose veins. The patient is placed flat on the back, the lower limbs slightly adducted. The operation is divided into four stages. In the first stage both testes are pushed toward the inguinal canals, and a pair of very much curved clamp forceps are placed crosswise, pinching up that part of the scrotum to be resected. With a bistoury all the tisues are divided. The forceps are then removed. In the second stage all the blood vesels cut, however small they may be, should be ligated. Complete hemostasis having been thus secured, the third stage is proceeded with, that of dissecting and ligating the varicose veins. The veins once isolated, a double thread of catgut is passed to make the ligatures on the two ends of the varicose veins, and the resection is done between the ligatures. The fourth and last stage comprises that of suturing the wound. This is done by planes, the deepest with catgut and the superficial ones with Florentine horsehair. An asptic dressing covers the wound. This procedure has the following advantages: 1. The resection of the scrotum has for a result the formation of a real and natural suspensory, which holds the testes in good position and prevents a recurrence of the trouble. 2. The wound is of sufficient size to permit of an operation for double varicocele, cyst of the cord, gumma of the testes, etc. 3. The dissection of varicose veins is made easy because one sees at a glance the component parts of the cords and thus avoids wounding the spermatic artery and the vas deferens. The author has used this method in 60 cases. Healing by first intention has followed in all, and the final result has invariably been satisfactory. There has been no recurrence in any case.

8. **Hot Horse Serum in Abdominal Surgery.**—See The Journal, xliii, page 1731.

12. **Pathology of Gout.**—Van Loghem corroborates the assumption that uric acid readily dissolves in the body fluids, and that sodium urate is precipitated in the body fluids when they contain a large proportion of uric acid. This precipitation of the crystals of sodium urate does not occur in normal tissues. The urate crystals may be taken up and carried away by the phagocytes. They are identical with the crystals found in the tophi of gout. These findings explain the attacks of gout that follow traumatism. The latter causes an exudation, that is, an accumulation of fluid containing large quantities of uric acid. The precipitation of the urate crystals causes the pain. The attacks that follow the grippe are explainable in the same way. It may be possible to study the therapeutic action of drugs by introducing sodium urate crystals into the body in collodion sacs, thus protecting them against the phagocytes.

13. **Purification of Waters Draining from Factories, etc.**—Calmette affirms that the problem of purifying the residual waters draining from sugar refineries and starch factories has at last been solved. The water is passed through three beds of aërobic bacteria. When it emerges, at the end of six hours, it does not putrefy and it is not injurious to fish. The city of Lille has placed every facility at his disposal for studying the biologic, chemic and chemicobacterial methods of purifying residual waters. He is now making a special study of the waters draining from each of the principal industries of the region, adapting the measures to the special conditions in each, as he relates in detail.

20 Prophylaxie de la maladie hydatique. F. Dévé (Rouen).
21 *Sur les ferments métalliques, leur action sur le métabolisme, leurs effets dans la pneumonie. A. Robin (Paris).

19. **Weakness of Vascular System During the Menopause.**—Pawinski has observed a number of cases of women, previously healthy, who during the menopause presented symptoms of cardiovascular hyposthenia, accompanied by nervous disturbances and predisposition to muscular fatigue. Bradycardia is more frequent than tachycardia, and the blood pressure is frequently much reduced. He attributes the trouble to ovarian insufficiency. Treatment should be along the lines of tonic and pressure-raising measures. The prognosis is favorable. The symptoms subside in a few weeks or months.

21. **Action of Metal Ferments on Metabolism and in Pneumonia.**—Robin announces that a solution of a metal, in a proportion of .00009 to .0002 gm. to the cubic centimeter, has a most remarkable action when injected subcutaneously. It displays a physiologic action like that of a true ferment, out of all proportion to the minute amount of the metal employed. The amount of urea may be increased by 30 per cent., in consequence, while there is liable to be a copious discharge of indoxyl in the urine and the uric acid may triple its former figure. The respiratory quotient is increased and the blood pressure transiently raised. The injection is followed also by leucocytosis. As certain of the vital processes are thus stimulated by these metal ferments, as he calls these extremely weak solutions of metals, he has tried to utilize them in the clinic. In pneumonia the phenomena observed during the crisis resemble those that follow injection of the metal ferment. In 14 cases of pneumonia an injection of from 5 to 10 c.c. of the metal solution hastened the crisis, the temperature dropping to normal before the seventh day, but the physical signs were not apparently modified. The metal ferments evidently stimulate the reaction of the organism, re-enforcing the natural resisting powers and superposing on the vital and personal reactions a parallel activity revealed by the more rapid disappearance of the correlative symptoms of the infection. He has treated 15 cases of pneumonia with antidiphtheria serum, normal horse serum, lactoserum or with yeast extracts, and their action seemed to be along the same lines as that of the metal ferments. He regards it as probable that the effect of these serums and of the metal ferments is practically identical. The latter may possibly substitute the former when more is learned in regard to their physical phenomena and biologic action. The therapeutic use of the metal ferments is an attempt to apply in the clinic the new data furnished by physics and chemistry in the last few years in regard to radioactivity, ionization and atomic energy, diastases, zymases, minutely divided metals and catalytic phenomena. The solutions are obtained by passing a small electric arc between metal electrodes submerged in distilled water. The metal passes into the fluid in the proportion of .09 to .2 mm. of the metal used to each c.c. of the fluid. A solution thus made displays a number of the reactions supposed to be peculiar to the organic diastases, and these reactions can be accelerated or inhibited by agents capable of influencing the diastases in the same way. The kind of metal used—silver, gold or platinum—did not seem to make any difference in regard to the results. He suggests that the effect may be due to a condition of the metal atoms similar to that noted in the vacuum of the metal atoms similar to that noted in the vacuum of the Crookes tube, the so-called "radiant state," in which the atoms are separated to the extremest limits, liberated, autonomous in their activity and susceptible of developing more energy. This hypothesis may explain the vital action of arsenic and iodin found normally in the tissues and also the remarkable therapeutic efficiency of certain mineral waters.

28. **Lead Poisoning from Wall Paper During Pregnancy.**—The puzzling case described has already been mentioned in the news columns of The Journal. Lefour comments on it to the effect that we are all living in an atmosphere of lead. The danger from this source in paint has been recognized, but now we have to contend with lead poisoning from wall papers. In 11 samples of papers obtained from different merchants 9 had a basis of lead and 2 of copper. He found 1.2 gm. of lead to the square meter in the paper which contained the least, and 7.68 gm. in the one that held the largest proportion of lead. The latter paper was of the class called velvet paper. Plush papers are probably still more dangerous, as they are constantly shedding a fine dust. In the case described, lead poisoning from the new wall papers was unmistakably the cause of the illness of the parents, of the death of the fetus in the first pregnancy, and of the premature delivery, with great debility of the fetus, in the second.

31. **Rupture of Circular Sinus During Labor.**—In 6 typical cases reported, 3 of the patients were i-paræ; the presentation was always of the vertex, while the children were rather under-sized. The hemorrhage was characteristic. As the uterus contracts, blood is forced out from the ruptured sinus and flows freely, but almost immediately the pressure of the head on the soft parts arrests the bleeding. As soon as the contraction is relaxed, the pressure of the head ceases and blood flows anew. The hemorrhage in one case kept up thus for forty-five minutes, during the entire period of expulsion. If there is no engagement, the hemorrhage is continuous.

38 La valeur diagnostique de l'absence du réflexe aortique de percussion. E. Rondot. Abstract.
39 *Cure of Epilepsy by Ligature of the Superior Longitudinal Sinus. H. Delagénière (Mans). Abstract.

34. **Ether Versus Chloroform.**—This article presents the conclusions deduced from a careful study of the literature of the last decade, in addition to experimental and clinical research. The authors are convinced that chloroform depresses the heart, the respiration and the blood pressure, while ether, in the standard dosage, does not affect these functions. They add that nerve substance exposed to the fumes of chloroform is killed, while ether fumes induce only a transient paralysis. The safety zone is much wider with ether than with chloroform, and the former does not have such an injurious action as the latter on the parenchyma of the various organs when the narcosis is long protracted. The consensus of opinion seems to be that ether is consequently less dangerous than chloroform, and that the pulmonary complications sometimes observed consecutive to ether anesthesia are not so much the fault of the ether as of the anesthetist.

36. **Fatal Hysteric Hemoptysis.**—Pende's patient was an apparently healthy young woman who suddenly began to exhibit symptoms of phthisis after a domestic scene. She coughed much, with dyspnea, the sputa being blood-stained but free from mucus, elastic fibers and bacilli. The fifth dorsal vertebra was painful to pressure, and there was irregular temperature, but no physical signs of a lung affection, although hysteric stigmata were prominent. She improved under suggestion, but the tuberculin test, twice repeated, gave a positive response. Inoculation of guinea-pigs was always negative. She was dismissed apparently completely cured, but succumbed soon afterward to a fulminating hemoptysis. Not a trace of tuberculosis could be discovered at the necropsy.

37. **Localization of the Nuclei of the Hypoglossal and Facial Nerves.**—Parhon gives illustrations of the nerve findings in a case of cancer in the suprahyoid region, comparing the findings with the peripheral disturbances. The conclusions confirm the results of experimental research in regard to the localization of the nuclei of the hypoglossal and facial nerves, as he describes in detail.

39. **Treatment of Epilepsy by Ligation of Longitudinal Sinus.**—Delagénière reports that in operating on an epileptic of 54 the longitudinal sinus was accidentally injured and was tamponed to control the hemorrhage. The patient was freed at one stroke from his epileptic seizures and has had no recurrence during the two years since. The benefit derived suggests that the seizure may be the result of a permanent dilatation of the veins on the surface of the hemispheres, causing irritation of the cortex. If the circulation in the cortex could be modified, the epilepsy would be cured. Delagénière has acted on this assumption in another case since, applying a double ligature to the longitudinal sinus near its end. The technic is similar to that of ligation of the saphena for superficial varices. The results were almost as perfect as in the first case. The patient was a man of 23 who has had no seizures during the three months since the simple intervention, the particulars of which are described in detail.

43. **Effect on Genital Sphere of Removal of the Thyroid.**—Lanz found that dogs, cats, goats and hens are usually unable to procreate after thyroidectomy. He has also observed the same effect in two human subjects. One was a man who was apparently deprived of all sexual functions by complete removal of the thyroid gland. Exhibition of thyroid extract, however, was followed by their gradual restoration. The other subject was a woman. The menses reappeared under thyroid treatment after they had been entirely suspended by thyroidectomy. This patient is unmarried. The other patient is married, but childless.

48. **Abdominal Surgery.**—Bakes mentions, among other experiences, that he has had three deaths for which he believes the scopolamin-morphin anesthesia was responsible. He has used this method of narcosis in 200 cases, but now discards it as uncertain and unreliable, except as an adjuvant for ether, for which it is very valuable, using minimal doses.

50. **"Inoculation Cancers."**—Milner does not regard any of the cases on record as conclusive in regard to the actual occurrence of cancer from inoculation during operations. The cancer cells may be attracted by way of the blood to the site of the wound, or the tissues may be injured by the cytotoxic fluids, etc. It has been found impossible to induce the development of cancer on intact epithelium by implantation of cancer cells, with the exception of the epithelium of the ovary. In every case reported of so-called "inoculation cancer" on any other epithelial surface it is impossible to exclude the possibility of retrograde metastasis or of multiplicity of the tumors. There is no positive observation on record of the unintentional

transmission of cancer from one individual to another of the same species. The prevailing fear of the contagiousness of cancer is probably exaggerated and unfounded, but at the same time none of the present prophylactic measures should be neglected. Further studies of these "inoculation cancers" may lead to interesting and important results. More than 200 articles were reviewed for this monograph, and the data are carefully analyzed and classified, with the above conclusions.

62. **Cure or Latency of Diabetes.**—Leo analyzes the cases of diabetes which have been published as cured, and describes one personally observed. The patient was a man in the thirties, and he seemed to be entirely free from any trace of his diabetes for a number of months. Symptoms then reappeared, and the literature shows that this recurrence is not exceptional. Some writers assume that it is a new onset of diabetes, but Leo inclines to believe that the disease persists during the interval, although in an imperceptibly latent form. In examining for life insurance it is advisable to pay great attention to a history of diabetes, and persons who have once suffered from the disease should always refrain from overtaxing their carbohydrate-assimilating functions.

64. **Chronic Lead Poisoning of the Eye.**—Lewin has for years been making a study of industrial intoxications and has recently published a large work on their effect on the eyes. Lead poisoning has a particularly pernicious action on the eyes, ranging from transient blindness to atrophy of the optic nerve, from retinitis with albuminuria to paralysis or cramps of the ocular muscles and the corneal opacity noted in persons employed in making the salts of lead. Among 163 victims of lead poisoning with eye disturbances, 122 were men and 41 women, the majority of the women being under 20, while the largest proportion of the men was between 30 and 40. In 36 cases which terminated in atrophy of the optic nerve, 19 of the subjects were women and 17 men. In 167 cases in which the eye symptoms were accompanied by other evidences of the lead poisoning, colic was noted in 79, vertigo in 11, headache in 52, cramps or coma in 47, paralysis in 27, arthralgia in 18 and deafness in 6. In 114 cases of lead affections of the eye, a cure was realized in 40, 22 were improved, 36 terminated in atrophy of the optic nerve, and 16 in death. He classifies 130 cases of these lead ocular affections according to the occupation, a list of 30 trades. One case was traced to wrapping chocolate in metal foil wrappers. There is a long stretch, he remarks, between the disturbances in the eye which could be revealed by ophthalmoscopic examination and those which the subject himself first notices. One eye may be seriously compromised before the patient realizes that anything is wrong. In 127 cases in which the onset was noted, the eye affection developed gradually in 84 and acutely in 43. In 100 persons employed in the vulcanization of rubber, 34 were cured, 25 improved, but 20 were unimproved. Lewin adds that scientific study of industrial intoxications generally has to contend with obstacles purposely thrown in the way by the proprietors.

66. **Incarcerated Hernia.**—Lessing reviews the 165 cases of incarcerated hernia treated at the Königsberg clinic between 1896 and 1903. The majority of the 40 cases of gangrene occurred with femoral hernia.

68. **Enterostomy in Prevention of Ileus.**—Busch advocates prompt enterostomy in case of peritonitis as a means of preventing closure of the bowels from the action of the inflammation around. He reports 2 cases in which ileus due to the action of the existing peritonitis was relieved by immediate enterostomy. In one case an opening was made three times and in the other twice. He emphasizes the great importance of free evacuation of the intestines in every case of peritonitis, without waiting for the suppuration or sepsis to assume large proportions.

69. **Gangrene in the Young.**—Barraud's patient was a young woman whose finger was injured and became red and swollen, but without suppuration. A gland in the axilla also became enlarged and painful. Six weeks later fever developed, with pains in the joints and later in the leg of the opposite side, with gangrene and death. Staphylococci were found in the swollen gland, but not in the white thrombus which plugged the iliac, femoral and hypogastric arteries.

71. **Ureteral Abscess Opened Through the Perineum.**—Neumann describes a case in which he evacuated an abscess at the vesical end of the ureter by way of the perineum.

75. **Treatment of Hydrocele.**—Klapp slits the sac and sutures the tunica vaginalis propria.

78. **Surgery of the Brain.**—The three cases of epilepsy reported were characterized by the traumatic etiology, the com-

mencement of the spasms in a certain part of the body and the absolute failure of all medical measures. The motor region was exposed by a Wagner bone flap in all three. In the first case five small cysts were discovered, and the patient soon succumbed to meningitis which developed after a prolapse of the brain. In the second case the center involved in the spasmodic turning of the head was determined by faradization and excised, the resected portion measuring 6 x 9 x 11 mm. The patient remained cured for six months, but then showed symptoms of recurrence. The brain was trephined again, and this time the patient remained free from symptoms for seven months. In the third (quite recent) case a fibroma was found in the falx cerebri. It was extirpated with good results to date. Reviewing the literature on the subject of the surgical treatment of epilepsy, Nast finds 84 cases recorded since 1889. Of this number 28 were not benefited by the intervention, but 25 were cured for at least a year, and 20 for a period less than a year. Six were improved and five died. Fourteen of the recoveries were in the 35 cases of traumatic Jacksonian epilepsy, and 8 recoveries in the 35 nontraumatic cases. Horsley excision of the cortex was done in 14 instances, with 5 recoveries. The cured cases have been under observation for from three to twelve years. The center involved was determined by electric tests in 11 cases. Only 3 of the 15 cases of general epilepsy were cured, and 13 of the 15 were of traumatic origin.

94 *Relations Between Nasopharynx and Genitalia.—Die Veränderungen des Nasenrachenraums bei Schwangeren, Gebärenden und Wochnerinnen. H. W. Freund (Strasburg).

94. Connection Between Nose, Throat and Genitalia.—Freund's later researches have confirmed his announcements in respect to the relations between the female sexual organs and the nose. In 66 out of 100 pregnant women he found hyperemia of the throat and hypertrophy of the turbinals, generally of the lower. These findings persisted throughout the pregnancy and were accompanied by epistaxis in 25 per cent. During the birth act the turbinals swell and induce reflex phenomena in the respiratory organs. These changes in the nose persist during the lying-in period without being influenced by nursing. Hypertrophied turbinals in contact may induce hyperemesis. Congestion and enlargement occur in the throat also, but much less pronounced, and generally only in the tonsils.

97-98. Vesicular Mole.—Wallart describes the findings in the ovaries in cases of vesicular mole and also during pregnancies, relating the particulars of a case in which a tumor developed after expulsion of a vesicular mole. In eight months metastases had developed in the lungs and in the vagina. Histologically it suggested a large-celled, blood-filled sarcoma. He classifies it as an atypical, malignant chorioepithelioma. Krukenberg also reports another atypical case. He advises prompt extirpation in dubious cases, without waiting for the uncertain findings of histologic examination.

102. Roldan's Method of Treating Inguinal Hernia.—In a typical case described, bilateral inguinal hernia had recurred on both sides. Roldan shows in five full-page illustrations the technic of his method, which does away with a separate suture thread for ligating the sac. The latter is included in the suture of the lower tier. He uses three silk sutures, all passed through a short piece of a drain, tied together in such a way that they will not pull out of the drain. The threads are then threaded in turn in a Reverdin needle and passed through and under the skin to a point 2 cm. from the upper corner of the wound, where they emerge. With one of the threads the lower tier is reconstructed, the needle being passed back and forth through the neck of the sac, as well as through the muscles. The sac is then resected and the tiers above sutured with the other threads, and the ends passed separately through another piece of drain. He never operates if the patient has the slightest catarrhal symptoms in the air passages. He removes the threads in from two to three weeks and has his patients wear a truss, with slight pressure, for six months at most.

105. Treatment of Fractures of the Lower Jaw.—The same author gives a number of illustrations to show the plaster bandage he applies in case of a fractured jaw and also the excellent results in 3 cases. The band passes across the jaw below the mouth, is then crossed at the base of the hair and is crossed again just in front of the vertex. One end is brought down over the cheek to below the chin and the other end over the other cheek, over the shorter end, and over the top of the head again and down to below the chin on the other side. The portion of the bandage where the strips cross at the base of the hair is then cut out and the two sides laced together. A cast thus made holds the jaw immovable while allowing free use of the mouth. It does not encroach on the face beyond the middle of the cheeks.

117. Modified Finsen Treatment of Hydrocele.—Roldan has devised a cooling ring to use with the Dermo lamp. It not only prevents the heating of the apparatus, but it also serves to absorb the heat rays. Applied in the treatment of hydrocele, he found that the lesion subsided entirely during the month after two 8-minute applications of the lamp. The hydrocele always shows transparent in the light of the lamp. The amount of fluid in the case described was from about 60 to 80 gm. The patient was a young man of 17, and his usual occupations were not interfered with in any way, nor were any inconveniences noted from the treatment. The application of the light *per se* is always indolent.

119. Thiosinamin Treatment of Keloid.—Presno relates that a rebellious, recurring keloid was cured by four injections of a 15 per cent. glycerin solution of thiosinamin. The lesion was on the back of the neck and had resisted all kinds of chemical cauterization. The injections were made every third day directly into the tumor which had developed subsequently to acne.

THE TREATMENT OF ACUTE ANTERIOR POLIOMYELITIS BY NERVE TRANSPLANTATION.*

WILLIAM G. SPILLER, M.D.
Professor of Neuropathology and Associate Professor of Neurology in the University of Pennsylvania, and
CHARLES H. FRAZIER, M.D.
Professor of Clinical Surgery in the University of Pennsylvania.
PHILADELPHIA.

Acute anterior poliomyelitis is generally recognized as an inflammation of the gray matter of the anterior horns of the spinal cord. The cases in which an examination of the spinal cord has been possible in the early stages of the disease have shown congestion of blood vessels, round cell infiltration about the vessels and within the nervous tissue, and more or less destruction of the nervous elements. The paralysis which occurs as a result of these lesions develops early in the disease and is usually extensive, and more so than at later stages. Some of the nerve cells of the anterior horns are so seriously damaged that they are incapable of regeneration, and the muscles formerly innervated from these, atrophy and lose their function. Other nerve cells are only seriously diseased and are still capable of at least partial restoration, and function returns later in the muscles innervated by these cells.

The representation of the muscles within the spinal cord is a matter of dispute and need not concern us in this connection. It is important, however, to bear in mind that in anterior poliomyelitis the muscles that remain permanently paralyzed represent nerve cells of the anterior horns which have degenerated, and that muscles which have recovered represent nerve cells which have regained their function. It is the usual experience that restoration of function in anterior poliomyelitis occurs in some of the muscles which at first were partially or even completely paralyzed, but this restoration, if it occurs, takes place within a few months following the onset of the disease. Certain muscles almost invariably remain functionless.

Medicinal treatment, massage and electricity are of little avail so far as these persistently paralyzed muscles are concerned; but there is in selected cases a hope for surgical intervention. In cases in which only one or two muscles of a group remain paralyzed, we may expect good results by uniting the nerve supply of these paralyzed muscles with a motor nerve in the vicinity, as in this way healthy nerve cells are brought into union with diseased nerve fibers and the latter may regenerate.

This procedure is not permissible within the three or four months immediately following the development of the paralysis, because, during this time, it is impossible to determine accurately which muscles will recover their function and which will not. Muscles that still remain paralyzed after six months are not likely to regain contractile power, and we are of the opinion that at the end of six months would be the most suitable period for operation, although recovery is still possible from operation at a later date.

Those cases in which a whole limb or the greater part of a limb remains paralyzed are not adapted to surgical treatment, and only those cases should be selected in which a few muscles are paralyzed.

Having these facts in mind, one of us (Spiller) proposed to Dr. J. K. Young that in a case of poliomyelitis of over two years' duration, in which the anterior tibial muscle alone was paralyzed, a nerve transplantation might be employed. The patient was a child. Investigations on the cadaver were made by Dr. Young to determine the method most suitable to the case. Dr. Young made an incision 10 cm. in length downward from the head of the tibia in the bony axis of the leg. The incision included the skin and superficial fascia. The deep fascia was divided on a grooved director, exposing the peroneal nerve. The nerve was followed down, and by separating the peroneus longus muscle three divisions were found: 1, The fasciculus of the nerves supplying the upper part of the anterior tibial muscle; 2, the anterior tibial nerve; 3, the musculocutaneous nerve; these divisions corresponding to those found in the cadaver. It was decided to take the upper division, of which there were four or five branches, and perforating the external division, the musculo-cutaneous, the former were united to the outer side of the latter by fine catgut sutures.

Great care was taken not to injure the musculo-cutaneous nerve any more than necessary, and the branches of the nerve which supply the anterior tibial muscle at its upper part were pushed through the incision in the musculo-cutaneous nerve without any attempt being made to separate the nerve fibers from the sheath. Small instruments were used, and the nerves were handled as little as possible.

The nerves which were anastomosed were divided as high up as possible, so that there would be no tension on them. The deep fascia was not closed with sutures. The skin was united by interrupted sutures. Over the antiseptic dressing a plaster-of-paris cast was applied to insure fixation of the limb.

This operation was done Dec. 4, 1902, and the case was reported[1] and the child presented before the Philadelphia Neurological Society, Feb. 24, 1903. At the time of presentation some improvement in the movement of the anterior tibial muscle was observed. At the present date the improvement is decided. The gait is nearly normal, and the child can draw up the inner side of the foot almost with normal power.

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

[1] Spiller and Young, Jour. of Nerv. and Mental Dis., June, 1903, p. 369.

In some respects this case was an unfavorable one for the operation. The child was too young to appreciate the importance of making voluntary effort to contract the anterior tibial muscle, the mother was not sufficiently intelligent to understand the necessity of bringing the child to the dispensary for regular treatment by massage and electricity, and the long duration of the paralysis made regeneration of the nerve doubtful.

About two months after this operation was done, one of us (Frazier) performed a similar operation in another case of poliomyelitis. The results so far have not been so good as in the case just described, but the child undoubtedly moves its affected limb less awkwardly, and the mother feels convinced that improvement in the gait has occurred. The case is as follows:

History.—J. S., aged 4, was always in good health until two years ago. About this time he was ill for some weeks with pneumonia. Just previous to the pneumonia he suffered from a fall from the hands of his nurse. He had been making some efforts to walk at this time. On recovery from illness his mother says his legs were weak and he was slow in learning to walk. History otherwise negative. An examination of the patient before the operation demonstrated paralysis only in the peroneal group of muscles.

Operation.—Feb. 28, 1903. This consisted in the performance of nerve transplantation in which the musculo-cutaneous nerve was grafted into the anterior tibial nerve.

Result.—The patient was discharged from the hospital on April 5, at which time there was no evidence of any restoration of function in the affected muscles. March 14. Extract from a letter received by Dr. Frazier: "He is getting along pretty well, but his leg seems much thinner and soft, his ankle seems very weak, but in other ways he seems well."

Examination by Drs. Frazier, Spiller and Weisenburg the following week: As far as could be seen there was no material change; that is to say, there was no change in the electrical reactions. The parent of the child seemed to think that he walked a little better and that there was a little less toe drop. This was not manifest to those examining. An infantile palsy brace was ordered for the child.

The operation of nerve transplantation recommended by one of us (Spiller) in these cases was devised in ignorance that any similar attempt had previously been made. It seems, however, that Peckham,[2] in 1900, performed nerve transplantation for the relief of paralysis in anterior poliomyelitis. His operation differed from those described in this paper, in that healthy nerve fibers were cut and united with degenerated nerve fibers. The cases in which this can be done are rare, as the surgeon naturally will hesitate to cut healthy nerves in a limb in which nerve fibers already are paralyzed. In reading the report of Peckham's case, one is struck by the long duration of the paralysis —ten years—and by the rapid restoration of partial function. It is stated that at the end of six weeks the toes could be extended (dorsally flexed) until they were perfectly straight, a motion that had been impossible until after the operation.

DISCUSSION.

Dr. Wharton Sinkler, Philadelphia, stated that he considers this one of the important advances which has been made in the treatment of poliomyelitis and he is sure that it is going to obtain a very prominent position in the treatment of cases where there is paralysis of an isolated muscle or group of muscles. It is frequently found that the anterior tibial group remains paralyzed when all the other muscles of the leg have recovered, and this gives rise to the flail foot which is so frequently seen in children suffering from this disease. The usual plans of treatment by electricity, massage and everything else which have been tried, have proved futile and he believes that there is a good field for this operation. He believes that a similar operation has been successfully done a number of times in cases of facial paralysis, that is, anastomosis of the seventh nerve.

Dr. Albert E. Sterne, Indianapolis, declared that nerve anastomosis is a new thing applied in a practical way in this affection. Experimentally, it was done some years ago, even before the transplantation by tendon suturing had been attempted. Dr. Weiner of Chicago has had a great deal of experience and has reported a number of cases, with excellent results in tendon transplantation for poliomyelitis. Dr. Sterne has done the operation a number of times, not only anteriorly but by taking the posterior tendon and bringing it through between the bones of the lower extremity in late cases of poliomyelitis. Care must be taken that the motor axis be exact. If this operation of nerve suturing can be efficiently done and the results demonstrated, so that nerve implantation will exert the effect of tendon transplantation, it would be the rational thing to do, because the nerve force will establish a practically normal function of the muscles already in existence. In tendon transplantation, on the other hand, to a certain extent, a particular group of muscles is disabled. Nerve implantation leaves all the muscles normal. In the old cases that usually come, unfortunately, after the disease has been in progress and has run its course for several months, or even years, the ordinary methods of massage, electricity, etc., are of little avail. In cases seen at the very beginning of the disease, where the acute manifestations are still present, these methods will meet with as good or better results than any other. When the period of regeneration has not yet begun, or during this period, if treatment is instituted results are far superior. When cases are permitted to go along until the regenerative period comes on, then the same results will not be obtained. Early interference with radical measures of a natural character, such as electricity and massage, are the proper measures, but in the late cases nerve implantation may well be the proper thing to do, if it take the place effectively of tendon transplantation. But even here other mechanical measures should not be neglected, for if they be persistently carried out they accomplish at least an added local nutrition to the wasted extremity and prevent its retardation of growth.

Dr. David I. Wolfstein, Cincinnati, considers that early interference in cases of anterior poliomyelitis is an exceedingly illogical procedure, because one would have to know to what extent the cord is diseased and to what extent the muscles are going to atrophy; otherwise, after surgical interference, atrophy might take place at a later date. If it is certain that the nerve to be selected originates from healthy nerve cells, nerve implantation might be the best method, but one can not be certain to what extent the anterior cortical cells are involved. Dr. Wolfstein is not convinced that electric treatment and massage in anterior poliomyelitis ever does much good. Massage does some good. A certain amount of tone is restored to the nervous system that depends on the amount of damage done the cord and the nerves involved.

Dr. C. C. Hersman, Pittsburg, Pa., declared that, in his opinion, six months would be rather early to operate. He has a case which has been under observation for three and one-half years, in which the use of the arm is slowly returning, which would not be improved by operation, as there are no normal nerves in the arm. For the last year, motion has been returning and the patient has some use of the arm. It is possible that he will eventually use it fairly well, though he will never have a perfect arm, as it is much smaller than the other. This motion returning after two years at least of non-use of the arm, seems to indicate that six months would be too soon to interfere. The return of motion might be attributed to the operation; on the other hand, if the child became worse, the parents and friends would attribute the worse condition to the early interference, and it would be better to wait twelve months at least.

---

[2] Providence Med. Journal, January, 1900, p. 5.

Dr. T. G. Weisenburg, Philadelphia, stated that the first case mentioned he saw both before and after the operation, and there was a very marked improvement. In the second case the improvement was not so great.

Dr. Howell T. Pershing, Denver, Colo., said that while in a disease that leaves such sad results as this one must be on the lookout for every improvement in treatment, it seems that the results of such an operation would have to be very critically examined before one could assign to it any definite value; certainly more than one or two cases would be necessary. Although most of the improvement usually occurs within three months, or at the most within six months, yet occasionally under the use of massage and electricity some improvment occurs in a muscle that has long been out of use, and after such an operation treatment would be apt to be applied with especial care. Dr. Pershing asked how the axis cylinders of the nerve are supposed to act on the muscle. He disapproved of the treatment of all cases of poliomyelitis in the early stages with electricity and massage. In any case of inflammation affecting the nerve centers the indications for rest ought to be observed until the inflammation has completely subsided.

Dr. Albert E. Sterne, Indianapolis, stated that he sees a large number of these cases and sees them early, and that in those cases where early remedial measures are taken the most excellent results are achieved. It is an absolute error to wait in these cases. No possible damage can be done with ice bags on the spinal column; it is only unfortunate that they exert so little action as they do. They are used in other conditions of inflammation; not to use them here is equivalent to cutting down the wires if the telephone is out of order. Electricity can do no possible harm in these cases seen early after the beginning of the inflammatory process. In these cases active measures do good, and waiting for the process of regeneration is not permissible.

Dr. W. G. Spiller, Philadelphia, stated that they are not at all radical in advocating this method of treatment. They should use it with a great deal of caution, and have said that the cases should be selected. He thinks that neurologists whose attention is directed to the subject will acknowledge that those cases of poliomyelitis in which the paralysis is limited to a small number of muscles are numerous; not a majority, but still numerous. In answer to Dr. Pershing's question, he stated that the subject of regeneration at the present day is a matter of great dispute. A few years ago most neurologists regarded this question as settled, and believed that the axis cylinders grew out from the central stump, and a regeneration from the peripheral portion of the nerve fiber. Later investigators have shown that the peripheral stump takes part in the regeneration. It is probable that the regeneration which occurs in the peripheral stump is not permanent, unless there is union with the central stump. The method recommended depends on the union of peripheral portions of diseased nerve fibers with healthy nerve cells and their axis cylinders. The period that should elapse before the operation is done is, of course, a matter of uncertainty. The longer the operation is postponed the less likely is it to be successful. It seems that six months would be the proper period; perhaps others may prefer a longer period. When this operation is done after a sufficiently long period, when further restoration of motor power is improbable, it can not in any way injure the child. The muscles have already become paralyzed, and cutting the nerve fibers supplying these muscles can in no way injure the child. The inserting of these diseased nerve fibers into the healthy nerve does not injure the nerve if properly done. Not all cases will be successful, but when the operation is successful decided advantages will have been gained over the method of tendon transplantation, because in tendon transplantation the muscle or muscles that have been diseased are thrown out of function entirely and use other muscles to perform a function which they have not been called on to perform heretofore. Nerve anastomosis restores the function of the paralyzed muscles where it is successful. The operation which Peckham performed in 1900 is remarkable on account of the long duration of the paralysis before the operation was performed and the rapid restoration of power. It differs from the operation here suggested in that healthy nerve fibers were cut and anastomosed with diseased nerve fibers. This Drs. Spiller and Frazier have not proposed, as by this operation, in most cases, one certainly causes paralysis in the region in which these healthy nerve fibers are distributed, and the operation is of very limited utility. Dr. Spiller is in the habit of using massage in poliomyelitis. He believes in all cases of paralysis it is our duty to keep the muscles in as good tone as possible until by natural processes their function is restored. Massage and electricity, he thinks, are useful in all cases of paralysis, especially in cases where recovery may be hoped for by natural means.

INTESTINAL OBSTRUCTION IN CHILDREN.*

JOHN F. ERDMANN, M.D.
Visiting Surgeon to Gouverneur Hospital and Clinical Professor of Surgery, University and Bellevue Hospital Medical College.
NEW YORK CITY.

I shall take up in this paper the chief symptomatic factors in intussusception, strangulated hernia, postoperative bands, etc., Meckel's diverticulum, devoting the major portion of my time to intussusception.

INTUSSUSCEPTION.

This disease, barring a few accidental cases, is one that demands prompt surgical interference. Each successive case I see impresses me with the necessity of making operations of urgency in these cases, and of not temporizing with air inflation or water injections. The diagnosis is not difficult, although the symptomatology, as given in former text-books on diseases of children, etc.. should be rewritten with a view of placing all stress on blood or bloody mucous stools, and not on the presence of a sausage-shaped tumor.

In over 60 per cent. of a series of 28 cases seen by me, 24 of which I operated on, no tumor of any kind was palpable per rectum or through the abdominal wall. I do not find, on searching my histories, a single acute case in which blood, bloody stool, bloody mucus or bloody serum was not found, either on the diaper, in the commode, or expelled from the anus after digital examination.

Symptoms.—Sudden pain is almost invariably the first symptom that the child manifests, then a degree of shock varying in intensity, and efforts at defecation take place; these are followed by manifestations of spasmodic pains; a peculiar whining cry or fits of crying. In the first hour or two the abdomen is lax, and no marked evidences of pain are produced on palpation; tumor is not felt unless the intussusception is of considerable extent and is taking place rapidly. After a few hours, depending entirely on the degree of obstruction, abdominal distension and evidences of complete obstruction occur. Although some feces and gas may be expelled with the bloody rectal contents mentioned, they are due entirely to the fact that these contents were below the point of obstruction. When a tumor is felt it is not usually the proverbial sausage-shaped tumor of our didactic days, but is more apt to be round or nodulated and moderately movable. Recently, in operating on a subacute case of six days' duration, a tumor was found that in every possible manner simulated a freely floating kidney.

---

* Read in the Section on Diseases of Children of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

There is invariably an accelerated pulse and an elevation of temperature of from one degree to two degrees and a half. I feel that the temperature noted in the majority of my cases has been due to absorption of some of the decomposed, foul-smelling, bloody rectal contents that were and are present in every case of over six hours' duration. In two instances the symptoms were of a subacute variety and rather puzzling, no blood having been observed in either case, only a little mucus, and in neither was there complete obstruction noted.

Subacute Intussusception.—Case 20.—(Operative Case 19.) Operated on after a period of six days duration with recovery. I am indebted to both Francis and Joseph Huber.

DR. JOSEPH HUBER'S REPORT.

"N. U. was seen for the first time Sunday, Jan. 25, 1903 (the prior history having no bearing on the present illness, is therefore omitted). The child looked well; temperature was 99. He complained of pain in the abdomen; the pain was paroxysmal in character and not localized in any special area. The mother was positive in her statements that the bowels had moved twice daily up to the previous twenty-four hours.

Codein, gr. 1/6 hourly, high injections, and cold or warm applications were advised.

January 26, restless night; temperature 99, same paroxysmal pain, slight resistance of right rectus, bowels moved twice after injections, a. m. and p. m.

January 27, temperature 96.6, condition the same; restless, with pain in paroxysms all night.

At 11:30 a. m. I saw the boy in consultation for the first time.

Examination.—General condition excellent, pulse good, about 80 to the minute; respiration natural and not accelerated; tongue clean, no odor to breath; heart and lungs negative.

Abdomen: both recti tense, no pains in right iliac fossa; palpation negative, as was also examination per rectum; no retention of urine or delay in the urination; no evidence of shock or collapse. The patient insisted on getting out of bed to use the chamber. Between the paroxysmal pains he would play with his toys and took great pride in blowing a fish horn. No blood or mucus in the stools at any time.

Symptoms.—Pain referred to the umbilical region and tenderness in this area were constant. Pressure over McBurney's point negative. Colicky pains, recurring at irregular intervals and severe in type, caused the boy to roll about and cry out. Both recti tense. There was some interference with the functions of the bowels, as they did not act as readily as in health. No urgent symptoms being present, it was decided to await further developments. If no improvement occurred in twenty-four hours an exploratory laparotomy was suggested, the suspicion tending in the direction of a mild inflammation of the appendix.

January 28: Temperature 100, pulse 104; p. m. temperature, 99; restless all night, pains in paroxysms continued. Two good fecal movements followed injections, made by nurse. Dr. John F. Erdmann was now requested to see the patient in consultation, and suggested an early exploratory operation.

January 29: Temperature 99, pulse 110; very restless and in pain all night. Bowels moved well (distinct fecal masses) after injection. The necessary arrangements having been made, the child was sent to Gouverneur Hospital and operated on by Dr. Erdmann at 3:30 p. m.

DR. ERDMANN'S REPORT.

When I first saw the patient, with Dr. Joseph Huber, he had all the manifestations of an appendicitis without any shock. He had had some so-called results from enemata. I suggested to them that the boy be submitted to operation as soon as possible.

Examination.—He was admitted to the hospital the next morning, Jan. 30, 1903, for operation, and when under ether, on abdominal and lumbar palpation no tumor was found in the appendicular region; but on subcostal palpation, a tumor about the size, and absolutely the shape of an infant's kidney was displaced and could be brought down into the right iliac region. This mass would slip back into the loin exactly as a floating kidney would, but it was evident that the tumor was intraperitoneal.

Operation.—The abdomen was opened, with a view of exploration, through the right rectus. Digital examination detected a tumor involving the cecum and colon with a slight portion of the ileum. This tumor proved to be an intussusception, which was readily reduced; the appendix was removed, and the abdomen closed without a drain. The patient made a perfect recovery and was discharged to his home in ten days.

This case, without question, was one of those varieties, subacute in character, no adhesions interfering between the separate layers of the intussusception, in which the bowel was not sufficiently constricted to produce the characteristic discharge or to induce complete obstruction. When I saw the child I spent quite a length of time at the history, with the possibility of an intussusception in view; but at this time all manifestations were those of appendicitis, except the constitutional manifestations due to pus, which one would naturally suspect at the end of five or six days, and I therefore suggested, as above stated, exploratory laparotomy. The question of appendicitis was readily eliminated when the child was under the anesthetic.

Movements of the bowel occurred with mucus, spasmodic pains with intervals of from one-half hour to an hour, a tumor not palpable until anesthetized, and then simulating in size, shape and motility a floating kidney. The condition only demonstrated by exploration.

Case 28.—(Operative Case 24.) The second case was one of eight days duration in a girl 22 months old, seen on the third day by one of our leading pediatricians. A diagnosis was not made. The case was seen by me on the eighth day, with the following signs and symptoms.

Symptoms.—A history of spasmodic pains, the child getting in the knee-chest position and crying out at intervals of thirty minutes. In the interim the child was either quiet or whining. Mucus was present, but no blood. Movements of the bowels occurred daily, but were due to rectal feeding. There was a movable tumor in the right side, but having no distinct outline. The child was in shock.

A diagnosis of intussusception with subacute symptoms was made.

Operation.—At the operation a gangrenous, irreducible, ileocecal intussusception was found. The appendix and ten inches of the ileum were excised. End to end suture anastomosis was employed. The patient died in six hours.

In this case I was satisfied that an intussusception existed although an appendicular mass had been suspected by the attending physicians.

Spontaneous Reduction.—Case 26.—A short time ago a case was referred to me by Dr. Francis Huber at about 11:30 in the morning. As I was unable to reach the house before 2 o'clock, I sent my nurses and assistants to prepare for operation so that no time should be wasted. On their arrival at 1:30 o'clock, they were told that the child had just had a distinct fecal movement, so that operation would not be necessary. The history of the case is as follows:

History.—Baby, 5 months old; was well up to 6 p. m. of the preceding day, when suddenly it was taken with a rectal discharge of pure blood, followed by vomiting. The mother said the child had agonizing pains, occurring at frequent intervals. When seen by Dr. Francis Huber at 11 o'clock of the following morning, i. e., the morning after the onset, the child was greatly depressed; the abdomen greatly relaxed; no stools since the preceding day; no tumor was palpable externally:

rectal examination was followed by the escape of about one ounce of offensive bloody discharge; no mass to be felt in the rectum or bimanually. The history further showed that an enema had been given some time before midnight, but nothing in the line of injections had been used following this time until the patient was seen by Dr. Huber. He, feeling that the symptoms were so pronouncedly those of intussusception, deemed it unadvisable for further interference other than surgical.

I was then called and ordered all preparation, as above stated, when, at 1:30 I was telephoned of the distinct fecal movement having taken place, and that the child's general condition was that which we see after a reduction of intussusception.

This spontaneous reduction evidently took place somewhere between twelve and fourteen hours after the injection had been used, and followed within an hour after the abdominal and rectal examination made by Dr. Huber. The mother said that from the time of the examination the vomiting and pain ceased, and that between 1 and 1:30 p. m. the bowels began to act.

The after-history of this patient was also typical of the cases we have reduced by operative procedure—that is, there was a foul-smelling, greenish diarrhea, which is almost invariably present, and is due to a superficial necrosis of the mucous membrane. In a comment by Dr. Huber on this case to me later, he said that in view of the history, symptoms and appearance of the baby with its foul enteritis (characteristic), he concluded that this was a fortunate case of spontaneous reduction, feeling that there could be absolutely little doubt on this score. I, personally, feel that this case was reduced largely through the manipulation, abdominal and rectal palpation, which simulated a massage. I certainly do not feel that the enema given about midnight could have had any influence whatever at so remote a time.

In the 28 cases seen by me twenty-four were operated on. One operative treatment was refused. Two are recorded as reduced shortly after the use of large enemata with inversion. One was recorded as a case of spontaneous recovery (see case No. 26) twelve or fourteen hours after injections had been used.

TREATMENT.

Rectal enemas in the first few hours are not productive of harm, but may, though rarely, be followed by reduction. This occurred but three times in the 28 cases seen by me.

Admitted that one meets occasionally with a reduction by the use of enemas, nevertheless this very important fact must be remembered, i. e., that the whole mass may be reduced but the ileocecal junction and one or more inches of the ileum. This being so, all the symptoms clear up for a time. They again return and necessitate operative interference at a time when the conditions of this region are not nearly so favorable to reduction, and may even require excision. This condition was well demonstrated in my sixteenth case, a male child, seven and one-half months old. Duration eight and three-fourths hours. injection used by the father, a well-known pediatrician, Dr. H. M. Silver, and myself was followed by a perfectly tranquil picture, but realizing the possibility of this condition of incomplete reduction, we all felt that the risk of exploration would be far less than that taken by leaving matters rest for farther manifestation. That our fears were not groundless was proved by the evidence of a mass at the cecum, which consisted of almost three inches of the ilium and the entire appendix. Reduction was readily accomplished, the appendix was removed, and recovery followed.

I should, therefore, not feel satisfied that reduction had taken place, even if the child should have no further manifestations of pain, etc., unless this was followed in a short time by a movement of the bowels that we could feel satisfied had come from beyond the supposed site of the previous intussusception; and that in the waiting interval for a movement we should be prepared to proceed at a moment's notice with the operative measures.

The use of enemas previous to operating is offered as a suggestion, and I can say that clinically it is of very valuable asistance, as there is no doubt that the injections reduce a portion of the intussusception, and any agency or procedure that limits operative time must of necessity diminish shock in direct proportion.

Although these little patients bear operative interference quite well, it is quite significant that my greatest mortality rate occurred in those cases which required the longest time for reduction, and that these cases were also the ones of longest duration. Enemas as a means of reduction are not advised after six hours time has elapsed from the first positive symptoms, as, after this period, much valuable time is lost by such procedure.

Anesthetic.—Chloroform has been the anesthetic used in all cases operated on by me, for the theoretical reason that vomiting may be a causative factor in producing this condition; therefore, the anesthetic that is the least liable to induce postoperative vomiting, which might reproduce the intussusception, should be used unless its danger to life in other ways is greater.

Operation.—The abdomen is prepared as in all emergency operations. The incision is invariably made by me in the middle third of the right rectus, and does not usually exceed two inches in length; the index finger explores the abdomen and then, if the tumor can not be delivered on the abdominal wall or into the incision, the latter is enlarged. Should the tumor be of considerable size, it is advisable, and even necessary, to reduce it in part as it lies in the abdomen, by compressing the distal end of the tumor in the proximal direction, i. e., so that the escaping intussusceptum can be seen or felt escaping toward the cecum in colonic or ileocecal varieties, and toward the duodenum in the enteric variety.

Traction as a means of reduction should never be used except in the lightest possible manner and then only with a view of directing the expulsion of the intussusceptum in its proper course.

Sometimes reduction occurs with a distinct pop; this is seen in the colonic and enteric varieties, but when the ileocecal valve is the part of the mass, great difficulty is often met with in reduction of the final portion. A little patience and gentle compression, aided with a backward and forward motion of the unreduced mass, allied to attempts at reduction and production of the condition is usually followed by success.

Occasionally a blunt instrument introduced between the intussuscipiens and the intussusceptum is of benefit in breaking up any adhesions, and may also be employed to dilate the tonic, contracted intussuscepiens.

When, as reduction proceeds, the tumor advances toward the right iliac region, it is advisable to bring the mass out of the abdomen before finishing the reduction. In each case, twelve in number, that I have operated on since January, 1902, I have removed the appendix before closing the abdominal incision, and in all but two of these the appendix was a portion of the intussusception. My reason for making the incision in the right rectus is due to the fact that the majority of cases are those invading the cecum and colon, and such being the case, the most frequent site of final reduction is that of the right lower quadrant of the abdomen. Even if the case is one of the sigmoid or enteric variety, this incision can be enlarged sufficiently to approach the most remote parts of the abdomen in children, without subjecting the patient to any danger of a hernia.

In case of inability to reduce the intussusception or when gangrene of the gut exists, excision with end to end anastomosis in the enteric or colonic varieties, and end to side anastomosis in those cases requiring excision of portions of both large and small intestines is necessary. Although occupying a few moments more time, this should be done before a patient is taken from the operating table.

In one case of over five days duration, in a male four months old, I was compelled to excise for gangrene and irreducibility six inches of the ileum and all of the large intestines to within four inches of the rectum, making an anastomosis between the ileum and the lower portion of the sigmoid. Death followed in a few hours.

Before closing the abdomen care should be taken to examine thoroughly the abdominal contents for multiple intussusceptions; the term multiple is used in contradistinction to the terms double, triple, etc., given by Edred M. Corner, M.B.,[1] to those cases in which double, etc., invagination takes place in one intussusception.

After reduction, the abdominal incision is sutured in the usual manner and a very tightly applied abdominal dressing is used.

After-treatment.—The after-treatment is of great importance. Paregoric, in sufficient doses to control peristalsis, is to be administered every three hours; barley water and milk, proportions varying with the child's age, are employed, and a small amount of bismuth, etc., is used.

The first day or two the child may have all the evidences of a foul, putrid enteritis with a temperature of from one-half a degree to two degrees elevation, the latter being thoroughly consistent with primary union in the wound.

My work for the past fourteen months consists of six operations with two deaths. One of these patients was doing nicely for twenty-four hours when he suddenly died. Dr. Francis Huber, to whom I am indebted for the case, was of the opinion that death was due to status lymphaticus. The second case was that cited as Case 28, operative case No. 24, where I excised ten inches of the ileum, etc.

I can not but feel that the citation of the two cases, one of spontaneous reduction several hours after enema, and the one of a subacute variety of over six days' duration with recovery after operation, are of sufficient interest to repay us for the time occupied in recording them in detail.

STRANGULATED HERNIA.

In a recent paper[2] on strangulated hernia in which I reported 58 cases, two were in children under five years. Since reading the paper I have had another, occurring in a male six weeks old, son of a physician. Two occurred on the right side, while the third was on the left. All were inguinals and occurred in males.

The left-sided hernia occurred in an infant not quite 13 days old. The symptoms expressed were those of irritability, crying, restlessness and shock. The protrusion, readily discoverable, is usually found by the mother while giving the child its bath. No differential diagnostic difficulty is experienced in these unless the case be one of atypical Richter hernia as occurred in the patient of 5 years of age. In this case obstruction was evident for several days. A small nodule in the groin, said by the mother to have been there for a considerable time, never varying in size, was taken for an enlarged gland. An abdominal section was made, and the protrusion found to be a small portion of a knuckle of gut (Richter's hernia), strangulated and gangrenous, requiring a resection. The case of a male, aged six weeks, was reduced after manipulation, no operation being necessary.

Since recording the 58 cases of all varieties of strangulated hernia, I have had 7 more, including the child of six weeks, cited above. There were 5 inguinal and 2 femoral, making a total of 65 cases, giving us about .046 per cent. occurring in children under 5 years in strangulated hernia of all varieties. If the inguinal variety alone be considered, and this should be, as I do not know of any strangulations recorded in the literature of femorals, ventrals, etc., in children of this age. I then have 31 previously reported and 5 additional cases in this paper, making a total of 36 cases in my recent practice, of which 3 were in children.

We then find .083 per cent. of all inguinal strangulations occurred in children under 5 years. The treatment in these cases resolves itself into: 1, Reduction, if possible, and in recent cases when the child is under 2 years the use of a properly fitting truss, relying on the possibility of a spontaneous cure. The six-weeks-old child has never had a recurrence in the six months past since reducing the hernia. 2. Operation with radical cure in all irreducible cases and all cases over 2 years, as the chance of spontaneous recovery with truss is relatively infrequent after this period.

POSTOPERATIVE BANDS, ADHESIONS, ETC.

It has fallen to my lot to have 2 cases of obstruction due to the above causes—one in a boy 6 years old after an operation for appendicitis in a Brooklyn hospital, and the other in a boy 10 years old following a drain operation for appendicitis.

Symptoms.—The symptoms of obstruction are the usual ones—constipation, meteorism, singultus, increased pulse, bad facies, temperature, vomiting as time goes on becoming fecal.

These symptoms are readily assigned to their proper source by fact of the history containing evidence of a previous operation. Both of these cases occurred after a period of from five to seven months had elapsed since the time of the original operation. This period of time corresponds to that cited in quite a number of cases reported in the New York Surgical Society, May 11, 1904.

Treatment.—The treatment in the cases occurring early, i. e., in from two to four weeks after operation, consists of elevation of the hips and body, high injections, etc. Should these not accomplish the result desired, operative means must be undertaken.

In cases occurring late, i. e., after from four to six weeks, precious time is lost by any attempt at mechanical relief, and operative procedures should be promptly instituted.

Prophylaxis.—As a means of preventing adhesive obstruction, I deem it essential to have a movement from the bowel of the patient within from twenty-four to thirty-six hours after the operation and one or more daily after that, and careful watching for not less than three weeks.

---

[1] Pathology and Classification of Intussusception, Annals of Surgery, 1903.

[2] Medical Record, March 12, 1904.

MECKEL'S DIVERTICULUM.

These abnormal conditions can produce obstruction in one of three ways, an instance of each one having been reported by me in past years.

First, the diverticulum may become inverted and act as a drag producing an intussusception. Case 2 in my list of intussusceptions.

Second, by strangulation by cords or band-like prolongations; two cases in young adults.

Third, by inflammation simulating appendicitis and producing obstruction either by means of parietal or visceral adhesion of the distal end, thereby forming a loop for strangulation; one case of a young adult reported by me; or by producing a general peritonitis with subsequent obstruction.

Symptoms.—The symptoms of obstruction by Meckel's diverticulum in types two and three are very similar to an appendicitis plus in a day or so a profound obstruction with or without a generalized peritonitis; while in appendicitis obstruction is not evident except in those cases accompanied by general peritonitis or in those exceptionally rare cases where the appendix overlies a portion of the intestine and acts as a band-producing or cord-producing obstruction.

I feel safe in saying that close observation of the literature of this subject will show that the great majority of cases have heretofore been operated on for appendicitis, and the actual condition was only found on exploration.

OBSTRUCTION FROM OTHER CAUSES.

I do not feel that the subject of obstruction in children has had proper attention without considering the obstruction peritonitis seen occasionally in pneumonia cases in which no visible lesion of the appendix or other abdominal viscus is evident. These cases simulate very closely those of intussusception or general peritonitis from appendicitis, and are usually differentiated by the fact that a pneumonia exists; that respirations are increased; that the appearance is of a livid or red-cheek character instead of pale and anxious, as in acute obstruction; temperature is higher than usual in obstruction; that no blood has been passed per rectum; that no mucus is present in the stool; that no mass is found in the right iliac region.

At the same time it must be remembered that a sufficient amount of fluid may be present in the peritoneal cavity to give a sense of fluctuation per rectum. The citation of the following case will impress itself on all: Recently I saw a case with one of our pediatricians for intussusception, in which I made a diagnosis of pneumonic peritonitis.

This patient was about 8 months old, had a lobar pneumonia, and with it a profoundly distended and rigid abdomen, complete obstruction, rapid and feeble pulse, and temperature of 102.5. At the time of the consultation I suggested exploration, although I felt that neither intussusception nor appendicitis was present. On returning in two hours with my assistants I found the child practically moribund, and refused to operate. Death followed in about two hours. Autopsy, abdominal only, revealed a general peritonitis; no other visceral involvement; appendix healthy.

The onset in these pneumonia peritonitis cases resembles an appendicitis, especially if the lower lobe be involved, pain is reflected down into the abdominal wall through the eighth, ninth, tenth and eleventh intercostal nerves, giving us rigidity over the spot seen at times in appendicitis cases.

It must be also admitted that a pneumonia and an appendicitis can occur at the same time. Recently I have seen such a case; fortunately the appendicitis complication became an enclosed abscess, and was successfully operated on after the right lower pneumonia had subsided.

60 West Fifty-second Street.

DISCUSSION.

Dr. A. Jacobi, New York City, asked Dr. Erdmann the age limits of the patients on whom he had operated; if he always removed the appendix, and, if so, why.

Dr. Isaac A. Abt, Chicago, believes that all these cases are not due to mechanical obstruction of the bowels; there are cases of paralytic obstruction which deserve consideration. We have all seen examples of complete intestinal obstruction in pneumonia and in the course of severe intestinal infections which proved on autopsy to be paralytic in nature. Two years ago a colleague asked Dr. Abt to see his child. She was suffering from an acute gastrointestinal infection. The child vomited and had loose stools for a time, later on this was followed by a condition of absolute obstruction. There was complete prostration; the face was ashen; the child refused all nourishment; the temperature was normal—at any rate, less than 100—the pulse and respirations were very rapid. The abdomen was enlarged and tympanitic. A surgeon was called in during the night and pronounced the case one of intussusception. He was mistaken, however, as the autopsy a few hours later showed. During the earlier stage of the child's illness the stools had contained no blood; simply large quantities of mucus. The child died, and at the autopsy every inch of the intestine was carefully gone over. It was much distended, but no obstruction was found. The liver was fatty, and on section resembled that found in fat necrosis. Dr. Abt has seen two cases recently that were absolutely similar to this one. The striking features were, first, the symptoms of intestinal infection; then the absolute obstruction of the bowels, the low temperature, the rapid pulse and respiration, the fatty degeneration of liver and other viscera, and death. He believes that these cases belong to a class which has not been sufficiently described in literature, and that they are the result of ptomain poisoning, depending on the ingestion of some kind of poisonous food. He does not believe that such cases of obstruction can be helped by surgical measures.

Dr. Louis Fischer, New York City, said that the results that he has seen in operations on children have not been so good as those reported by Dr. Erdmann, and he attributes this to the fact that children do not bear the shock of laparotomy well. He has seen a series of cases in which laparotomy was done, and all the patients died. The fatal result in these cases might be attributable to several causes, one of which was a slow operation and shock. He would like to know whether rapidity of operating is not an important factor, so as to lessen the shock. The following case came under his observation recently. A child, apparently well in the morning, was taken suddenly sick in the afternoon with symptoms of constipation and considerable abdominal distension. In the evening the abdomen was still more distended. He saw the child at 9 o'clock, 12 hours after the first symptoms appeared, pronounced the case one of intestinal obstruction and suggested an operation. The operation was delayed till the following day and resulted fatally. The child was moribund at the time of operation.

Dr. S. W. Kelley, Cleveland, gave it as his opinion that spontaneous reduction occasionally occurs and may take place under the use of opium. If there is any time at which opium is useful in intussusception, it is in the beginning, but it should not be depended on. There are cases in which the use of air or water as a means of reduction is useful, and sometimes it must be adopted as a matter of necessity, as a laparotomy is not always permitted by the parents. The introduction into the bowel of air or water, when properly done, is sometimes followed by reduction, and Dr. Kelley does not think the method should be altogether dispensed with. Very little is said in regard to the way in which it should be applied, the amount of pressure that should be used, nor the length of time the pressure should be maintained. Dr. Kelley thinks the figures that Morris gave some years ago placed the pressure at 8 or 9 pounds, which appears to be too high. He believes that air pressure is preferable to water pressure in very many cases, but it is so difficult to measure that he finds it succeeds best by using air first and then following it with water, which is more easily handled, and by means of which the air pressure can be measured. He prefers a pressure of four or five pounds, keeping it up for a period of 15, 20 or 25 minutes, and believes that this is more effective than a higher pressure for a shorter time.

Dr. Samuel McC. Hamill, Philadelphia, said that it has been shown that irritation of the rectum produces reversed peristalsis, and this fact may have had some bearing in producing spontaneous reduction in the case reported by Dr. Erdmann.

Dr. A. Jacobi, New York City, considers that the phenomenon mentioned by Dr. Hamill would not be of any practical value in the treatment of these cases, because the reverse peristaltic wave would undoubtedly be interrupted at the point of intussusception.

Dr. John Lovett Morse, Boston, reported that the experience at the Infants' Hospital in Boston is that babies not only bear laparotomy but other severe operations very well, providing they are kept warm during the operation. All the patients who are to undergo an operation are wrapped in cotton and placed on a special operating table, which is kept warm.

Dr. John F. Erdmann said that eight or ten years ago Dr. R. T. Morris produced reversed peristalsis by irritating the rectum by the use of chlorid of soda, to determine what portion of the intestine he was dealing with—whether the afferent or the efferent portion. Dr. Erdmann considers that it is not only time lost, but that it is very apt to prove useless, because the colon and the rectum will not hold the amount of pressure we wish to use. The sphincter will not hold the water in the bowel. With both air and water the danger of producing a rupture of the bowel is very great. If Dr. Kelley could see the difficulty Dr. Erdmann has experienced in reducing an intussusception with the fingers after the abdomen is opened he would never again resort to the introduction of air or water. The coats of the intestine are soggy and edematous, and unless great care is exercised in the reduction, a rupture of the serosa and musculosa will occur. While Dr. Erdmann does not favor the use of injections, he would not object to their use during the first six hours. Among his last six cases there were two deaths. In one, the cause of death was given as status lymphaticus; the other patient died after an extensive resection, with end-to-end anastomosis. There is no question that the more rapid the operation, the less the shock, and the latter is frequently the cause of death. The youngest child he has operated on was 14 or 15 weeks; that patient recovered. Children, as a rule, bear operation well. He has recently operated on 22 cases of appendicitis, all under 5 years of age, with a mortality of 9.9 per cent., and at least 14 of these cases were of the septic type. In the majority of his cases of intussusception, the operation was done within 15 or 20 minutes. If those cases that he operated on were not mechanical, then he does not know what constitutes a mechanical obstruction. An intussusception will occlude the caliber of the gut as completely as a wad of cotton, and even more thoroughly. The paralytic type of obstruction does occur, particularly in pneumonia in children, when there may be a general pneumococcus peritonitis, with paresis of the bowels, and death. The majority of his patients were under 1 year old: two of them were over 5, and the rest under 3. He removed the appendix because it could be done without complicating or lengthening the operation to any extent. He thinks it wise to do so because it prevents the formation of subsequent adhesions and a second abdominal section.

CHOICE OF A TIME OF ELECTION IN MASTOID OPERATIONS.

SOME CONSIDERATIONS ARISING FROM THE DIFFICULTIES OF THE CHOICE—PROSPECTIVE RESULTS.*

D. A. KUYK, M.D.
Lecturer on Diseases of the Nose and Throat, Medical College of Virginia.
RICHMOND, VA.

Although voluminous articles, reports and discussions have appeared on the subject of mastoiditis, the mastoid operation and its ultimate results; indeed, experiences so exhaustively detailed that it would seem the searcher after truth might find his way without groping, yet perplexities that defy satisfactory decision so constantly confront the otologist, that I have chosen to place before you some such perplexities as have arisen for me in the recent past; and especially the choice of the proper moment for most advantageous operation.

This paper deals with well-to-do private patients, with whose intelligence it is undoubtedly more difficult to co-operate than in the case of the ordinary grade of dispensary subject. For, adding, in the former instance, to the difficulty and confusion which the conscientious worker experiences at times in his own mind, and at a moment, too, when most he needs to be unhampered in power to decide, there are presented to him by relatives and friends such questions and demands for positive answers that the picture of uncertainty is complete for him. While in the latter instance with the usual dispensary patient, one may follow a more independent and assured attitude, more easily ignoring inconvenient demands for enlightenment on the problems involved until one has arrived at some satisfactory solution of the best course to pursue.

So varied, too, are the final chapters in the histories of these cases, even after the otologist has had freedom in following his best intelligence, that they are at times quite inexplicable to him. Although reports of cases, like statistics, may be made to serve most contradictory ends, and are therefore not so useful as they might be, yet I wish to enforce and illustrate my theme by a few experiences which I will relate as briefly and relevantly as possible.

For the sake of logical discussion I have grouped these cases as follows:

Group 1. Features obtaining in mastoiditis as a complication or a sequel of the exanthemata.

Group 2. Features obtaining in mastoiditis as a complication or a sequel of influenza.

Group 3. Features obtaining in mastoiditis as occurring in the course of chronic suppurative otitis media.

As an object lesson looking toward the more intimate discussion of each of the above-mentioned groups it becomes necessary to study briefly the histories of cases apparently similar, yet with results widely divergent.

REPORTS OF CASES IN GROUP 1.

Case 1.—Female child, age 6 years. Scarlet fever of severe type of six weeks' duration. Subsidence of all symptoms except slight fever never ranging above 100.5 degrees. Without premonition, many days after apparent convalescence set in, pain began in the right ear.

Examination.—This revealed a highly congested, slightly bulging drum membrane, no sagging of the posterosuperior canal wall, mastoid sensitive to pressure.

---

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

Treatment.—Free incision of drum membrane was followed by sanious discharge, which continued for ten days, during which time the temperature remained unchanged—99.5 degrees in the morning, 100.5 degrees in the evening—but with subsidence of all pain and mastoid sensitiveness.

Result.—Gradually the discharge from the ear diminished, then ceased, the incision closing, while the temperature remained within the same range for more than two weeks longer, when it at last became normal. Since this time the child has been in fair health, with unimpaired hearing. Frequent examinations were made by her physician during this time, but they failed to reveal signs of any intercurrent affection other than a pronounced anemia.

Observations on Case 1.—The long-continued course of slight fever in this case, almost a month after incision of the drum membrane, aroused constant suspicion of the presence of purulent deposit in the mastoid. Consideration also, of Ponfick's findings of 91 per cent. of the case of autopsy after exanthematous diseases as showing unsuspecting mastoiditis, did not tend toward lessening my apprehension in the study of this case, and he was long in doubt of his wisdom in postponing operation. But though return to health was discouragingly slow, yet in the absence of more decided symptoms, patience prevailed and in the end recovery seems complete.

There still remains, however, this same doubt of the superiority of so conservative a course, and the query still arises were it not better to have opened the mastoid and perhaps removed some slight focus of purulent deposit and hastened this recovery; and when in the course of this case ought this to have been done? Recourse to the bacteriologic examination of the discharge should theoretically help to aid in answering both these questions, but the systemic condition following the exanthemata varies so greatly with regard to vulnerability to bacterial attack, that practically it is extremely doubtful if the bacteriologic findings furnish a safe index for guidance in these cases.

CASE 2.—Male, 5 years old. Scarlet fever of severe type of four weeks' duration.

History.—Desquamation had ceased for ten days, the child was apparently doing well but for a continued elevation of temperature—99 to 100.75 degrees. After this had continued for ten days pain in the right ear began.

Examination.—When examined two days later the drum membrane was reddened and slightly bulging, no sagging of posterosuperior canal wall, nor was there tenderness on pressure over any part of the mastoid.

Treatment and Result.—The drum membrane was freely incised, liberating a moderate quantity of blood and pus. Pain promptly ceased but no fall in temperature occurred. The usual antiseptic treatment was ordered. Discharge of an odorless pus continued for two weeks. Repeated and careful examination failed to reveal other than the aural disease. Notwithstanding an unchanged temperature range the child gained considerably in strength, sat up in bed, later on played around the room, still showing no other symptoms than the slight temperature and the aural discharge. Very gradually the suppuration lessened both in quantity and consistency until only a colorless, mucoid discharge remained. So much improved had the conditions become that only an occasional visit, perhaps twice a week for three weeks, was made, when, without warning or apparent cause, the ear symptoms became suddenly aggravated, moderate ear pain ensued, with slight mastoid tenderness; the discharge was, however, unchanged. A slight though frequent and annoying cough began. The following day all the symptoms were more pronounced, temperature 103.5 degrees. There was now very slight swelling over the mastoid. The morning of the third day the mastoid was swollen and edematous, auricle displaced and immediate preparation made for operation.

Operation.—Immediately on incision a very considerable quantity of foul-smelling discolored pus was evacuated. The sinus leading to the mastoid antrum was readily found, the entire mastoid process was carious, only a curette being used to remove the diseased structure. The carious process had extended to the wall of the lateral sinus, which, owing to its anomalous position almost under the antrum, was perforated by the curette. Profuse hemorrhage indicated its freedom from thrombosis. The ruptured sinus was closed by a Mikulicz dressing and the operation completed. Recovery, with perfect hearing, ensued after two months.

Observations on Case 2.—It is to be observed that Case 2 presents an exactly parallel history with Case 1, in every particular except the former, Case 2, lacked mastoid tenderness. It seems highly improbable that the extensive necrosis found should have occurred in the two or three days preceding operation. Yet the extremely dangerous condition supervened with such apparent rapidity that I can not but believe that the time for most advantageous operation must have passed at some time during the five weeks of stationary temperature. Without, however, any signs except slight discharge, a marked grade of anemia and a moderate temperature, an exploratory mastoidectomy seemed to have been unwarranted.

CASE 3.—Female, age 3. Scarlet fever.

History.—During the desquamative stage acute otitis occurred in the left ear. The drum membrane perforated in two days. When seen, copious discharge was issuing from ear. Treatment only slightly modified the character and quantity of the discharge, yet the patient gained in strength so that she was brought to the office for two weeks for further treatment. Then pain of paroxysmal character began around the ear, temperature 100.5, no change in discharge, no mastoid tenderness at any time. On the fourth day slight edema over mastoid.

Operation.—Operation on sixth day revealed mastoid full of pus, complete necrosis, only curettement being necessary to clear away debris and enter antrum.

Observations on Case 3.—This case is so perfect a counterpart of the other two cases of this group up to the date of aggravated symptoms just preceding operation that there is due its discussion the same pertinent inquiry, ought exploratory mastoid operation to have been done during the weeks in which general improvement seemed in progress, and without other guiding symptoms than slight aural discharge with occasional slight elevation of temperature?

Examples of this group of cases might be multiplied with a quite unvarying symptom-complex, until perhaps, three to six weeks had elapsed in each case; the outcome in some cases being smooth, unexpected recovery in the end; in others, unequivocal demand for undelayed operation following sharply on what seemed a slow but satisfactory course of convalescence.

Bacteriology may in the future furnish the coveted data pointing to the need of operation during these latent intervals, but reinfection by streptococci during an otitis media of several weeks' duration is not only possible, but probable, especially in scarlet fever cases, or indeed in any of the exanthemata. Further, no private patient with the mild symptoms detailed above would permit a disfiguring operation though the presence of streptococci prognosticated eventual surgical interference. With a hospital patient whose time is important and who can have little care at home, the aspect is a totally different one and the bacteriologic examination ought to have due weight in arriving at a decision.

REPORT OF CASES IN GROUP 2.

Case 1.—A thin, pallid woman aged 41 years.

History.—Had bronchopneumonia following grip, when she was attacked by acute otitis media of unusually severe nature.

Symptoms.—Pain violent and constant. Temperature 102.5 degrees. Drum membrane freely opened, releasing a quantity of sanious discharge. Pain was in nowise modified, radiating over entire side of head and neck, without ceasing. Considerable sensitiveness over mastoid and antrum, especially at tip, and over sternomastoid muscle, for several inches downward. At no time was there any edema or redness over mastoid. Copious discharge through external auditory canal and eustachian tube. Temperature remained 100.7 degrees a. m., to 101 degrees p. m.

Termination of Case.—Operation strongly advised, but positively declined because patient knew of one case of mastoid operation that at the end of one year was still unhealed. Indications were unmistakable for operation, but she persistently refused, and after about ten days recovery began and progressed slowly. There was much deafness and occasional severe pain about the ear and radiating about the head, especially the occiput, evidently indicating a resorptive process in antrum and mastoid cells.

Observations on Case 1.—As will be seen this case gave fairly urgent indications for operation. A recovery of rather an undesirable character seems to be in progress, for a possible operation still faces the patient. There is marked deafness which might have been escaped and the general health is very surely menaced by leaving nature to cope with the infection alone. It presents, however, an illustration of the difficulties of prognosis in cases of mastoid involvement.

Case 2.—Woman, married, aged 28. Grip of three days' duration; when first seen temperature 101 degrees. Right drum had perforated with copious discharge; left ear acutely inflamed, membrane bulging, great pain.

Treatment and Result.—Membrane promptly incised, followed by profuse discharge of pus. Hot bichlorid irrigations every two hours gave some relief; temperature next day 99 degrees. During that night pain in the left ear recurred persistently. On morning of third day mastoid tenderness and frontal headache. Leiter coil applied for forty-eight hours. Mastoid swelling and tenderness slightly modified, temperature 99 degrees, with violent headache and pain in and around the ear. Discharge from right ear continued profuse, while that from left ear much lessened. No improvement by treatment; patient sent to hospital on fifth day for operation. Here much pus was expectorated, the incision in left drum membrane almost closed and discharge ceased.

Operation.—A diploëtic mastoid antrum was found filled with granulations, surrounding bone softened. Complete subsidence of the severe pain followed the operation; patient left hospital on the fifth day and on the seventh was sitting up, quite well and strong. She is now, at the end of three weeks, completely recovered, with excellent hearing.

Observations on Case 2.—The parallelism of these two cases as well as the contrast between them is so evident that they need little comment. The local and general conditions in each before operation were quite similar, minus the bronchopneumonia in the second case, while the operation undoubtedly changed the picture entirely in Case 2, from a slow, painful, doubtful and unsatisfactory recovery to a prompt and desirable one.

Group 2, unlike the examples in Group 1, offered no difficulty in deciding on the necessity for operation, nor as to the time for this procedure. One prominent feature to be observed in the history of these cases, as well as in that of several others, occurring recently and here unrecorded, and which were by prompt measures aborted, is the very rapid sequence of symptoms which I have noted as characteristic of aural complications of epidemic influenza.

REPORT OF CASES IN GROUP 3.

Case 1.—Woman, aged 40 years. In poor health, anemic, hysterical, constant headache, which had been attributed to some uterine trouble for which a number of curettements had been done, without result.

History.—Had had suppuration in left ear for several years. Had tried many treatments but without avail. Discharge thick, tenacious; foul odor; carious bone. Pain over mastoid marked though inconstant. Temperature normal.

Treatment.—The case was treated tentatively for three weeks without improvement, and the Schwarze operation was done. Mastoid carious, much pus; the antrum and cells were carefully cleansed, the aditus enlarged, the attic curetted; thorough drainage obtained. Wound healed kindly, absolute cessation of suppuration, complete relief from headache and hysterical state, and health completely restored.

Observations on Case 1.—The severe and unremitting head pain and the hysteria which had been for years ascribed to uterine disease were completely relieved by the removal of the focus of disease within the mastoid. There has been no complaint of uterine disease since restoration to health took place.

Case 2.—Woman, aged 38 years, in fair physical condition.

History.—For several years prior to her first visit she had had pain over the right mastoid which was considered neuralgia, but without apparent middle ear involvement until an unusual exposure caused severe chilling and cold. Pain then became violent, drum quickly ruptured, profuse purulent discharge without cessation of mastoid pain.

Examination.—When seen at the office, temperature 99 degrees, muscles of neck of right side rigid, profuse discharge from a large perforation in drum membrane, mastoid exquisitely sensitive, hearing reduced to loud voice close to ear; immediate operation.

Operation.—Mastoid carious, antrum very small but filled with pus, aditus unusually large, no necrosis detected in middle ear. Entire mastoid process removed and free drainage through middle ear established.

Result.—On following day temperature 98.5 degrees, stiffness of neck muscles subsided, suppuration entirely ceased, and on third day patient was going about feeling well. Hearing has become almost normal, ear dry, health good.

Observations on Case 2.—From the extensive caries found after a few days of illness, it seems probable mastoiditis was present perhaps for a long time before the exposure which resulted in the exacerbation. However, could the aural surgeon have advised operation with positively no sign to guide him but occasional severe pain of neuralgic character in the mastoid?

Case 3.—Woman, aged 52 years. Anemic and rapidly losing health and strength.

History.—Has had middle ear suppuration from left ear since ten years of age. Recently the discharge has become very much worse. It would suddenly cease for a day or two, during which time there was intense pain in and around the ear, radiating to the forehead and accompanied with considerable vertigo. These attacks of pain and vertigo became more frequent.

Examination.—When she presented at the office there was a profuse discharge flowing from the ear, of foul odor and thin as water. The superoposterior canal wall was bulging and sensitive; pressure over mastoid painful to only slight degree. No redness nor edema over mastoid. There was no displacement of auricle. Temperature normal. Immediate operation was advised and accepted.

Operation.—The mastoid was very small antero-posteriorly, diploëtic and ivory hard, the antrum almost obliterated and very deeply placed; only a small quantity—a few drops—of pus was found in the antrum, but the surrounding bone was carious down to the inner table of the temporal bone, which was chiseled away until the dura exposed, which was found to be smooth and healthy. Fully two-thirds of the small mastoid was removed, and this opening was made continuous with the middle ear; thus a modified radical mastoid operation was done. The closure of the wound differed somewhat from that ordinarily employed. The posterior flap was dissected from the skull for about two inches, then drawn forward and stitched to the auricular flap, leaving an opening at its inferior end for drainage, a gauze wick was inserted and removed on the third day, and as the reparative process was satisfactory it was left out and the wound allowed to granulate, which, since there was perfect apposition, it did promptly. Drainage was then secured only through the external canal. This procedure has given me the most satisfactory result.

Result.—There remains absolutely no deformity. At the end of one month the bandage was discarded and the patient resumed her usual duties. The ear is not entirely dry, but the discharge is only serous, slight and odorless.

Observations on Case 8.—The length of time of continuous aural suppuration without ill effect until the sudden exacerbation a few weeks prior to the operation is rather unusual.

It is to be observed also, that there was total absence of fever, mastoid swelling or redness, the diagnosis being made from the sagging posterosuperior canal wall, the pain and the vertigo. It must appear evident, that to have awaited the appearance of the so-called classic symptoms, which should determine the time of election of operation, would have exposed the patient to dangerous complications.

CONCLUSIONS.

In conclusion, it will be a source of helpfulness and gratification not only to me, but undoubtedly to those of the profession who may be interested in the transactions of this Section, if this paper shall elicit a free discussion on its various aspects; and especially would it seem valuable to find a consensus of opinion of this body on the question whether exploratory operation on the mastoid in obscure cases is ever justifiable in the absence of positive indications. While inclined to conservatism regarding exploratory operation on a suspected mastoiditis, I feel that a sin of omission in these cases is a serious one.

Some authorities have striven for definiteness on this subject of an opportune time for operation. It is possible in a condition presenting so varied a symptom-complex as at times does mastoiditis, that an elected time for operation might not be said to be a practical offering to our present wisdom on this subject, but it seems that some nearer approach to a definite rule might be arrived at through discussions of this deliberative body. Others have grounded on this same rock of hesitation and uncertainty, and the transactions of this Section show other requests for discussions that should advance toward the formulation of definite rules on this subject.

As I have indicated, the opinion of the best workers this field, but by these conservatives such varied rules are given as permit a latitude, within which decision may be remarkably perturbing to the surgeon. As in all work the good judgment of the operator must needs play its part, and to no greater extent in other surgical work does accurate and careful observation and deduction make for success than in the varying phases of an acute, supposedly suppurative mastoiditis.

As I have indicated, the opinion of the best workers in this field abroad favors waiting a longer time than it seems safe here to do in many instances, and I am persuaded that the rapidly infected mastoid following the exanthems and influenza here do not obtain in like measure abroad. From a very general survey of this subject, conjoined with my most intelligent prospective and retrospective study of the cases occurring in my work in the past few months, I am led to the conclusion that it is perhaps not possible to fix on a closer definition of the chosen time for operation than may be deduced from the following rules:

1. Delay in operation of cases belonging to the first two groups herein treated, should not be permitted beyond from thirty-six to forty-eight hours, if profuse discharge from the middle ear by incision or rupture, with ice to the mastoid and general antiphlogistic measures do not markedly improve the condition. Even with normal or slightly elevated temperature, if there is edema over the mastoid and sagging of the posterosuperior wall of the external canal, operation should not be delayed, for with what seems to be an improved general state, in the majority of cases operation will eventually be needed.

2. Cases showing infection with streptococci, while at time for days the symptoms lie in abeyance, such cases should not be treated tentatively on appearance of pronounced symptoms of aggravated pain about the ear, fresh rise of temperature, lessened or suppressed discharge from middle ear, but should be operated on without delay in order to prevent the extensive caries which occurs in from two to three days in such infection.

3. In cases of slow, painful recovery, even if promising in the end to be complete, it would be wise to operate after a reasonable period of observation, in order to assist nature in her task.

4. Since this paper deals with private patients who are seen without undue delay, and who have usually had the benefit of good care of a palliative kind, it may be stated that as a rule applying to these cases of chronic otitis media, that the radical operation with its disfiguring results may quite often be replaced by the simple operation conjoined with careful curettage of the middle chamber.

5. Cases of chronic otitis media may be permitted more latitude, if there arise no signs pointing to intracranial involvement. However, if there be present constant otorrhea, neuralgic pains over the part, lowered general health, with nervous irritability, perhaps vertigo, operation should be undertaken after from two to six weeks, if treatment has failed to relieve the condition.

As a last word I wish to disclaim any hope to offer novel material to this interesting and widely discussed subject. I have told my experiences and propounded queries which have confronted me while undergoing these experiences; and have offered rules not exhaustively applicable to all imaginable cases, but serviceable to me in dealing with the groups herein treated; and withal seeking in discussion more light. The various important surgical procedures all have a few characteristic features on which to base unequivocal indications for operation. Independence to the individual operator would undoubtedly be gained through a concurrence of conviction on this theme by the members of the Laryngologic Section of the American Medical Association.

DISCUSSION.

Dr. B. A. Randall, Philadelphia, referred to the frontiersman's phrase: "If you see sign of Indian, be careful; no sign of Indian, more careful." That is true of disease of the middle ear. The symptoms may be obscure while destruction of a deep-seated character is going on, usually because dense cortical tissue is shutting in the process and its symptoms. If patients have been made to understand that they have but one chance and they take that chance and recover withou. operation, one can only tell them they have been extremely fortunate and that it is a consolation to give other patients in the future. Dr. Kuyk will probably hear from that mastoid yet. Frank confession of difficulties in these operations may encourage younger men in their work, showing them that every one must do his best earnestly and conscientiously to make the fewest possible mistakes.

Dr. J. F. Barnhill, Indianapolis, said that, in a considerable number of cases of mastoiditis, in which the mastoid operation should be performed, the condition is almost symptomless, there being present no pain, fever, redness nor swelling. We must take into account the fact that the discharging ear does not show a tendency to dry up, and that in most instances the amount of the flow is out of all proportion to that which could possibly come from suppuration in so small a cavity as the middle ear alone. Since external evidences of mastoid involvement are often wanting, and when present do not always indicate the gravity of the ailment, most thorough otoscopic inspection and examination by every known means becomes an essential. Sagging of the posterior superior meatal wall is, of course, a most valuable indication, but unfortunately is not always present. Politzer says that if there is a pulsating light reflex on the bead or pus which projects through the drum membrane after cleansing the external meatus, and persisting two weeks after its rupture, it is certain evidence of disease of the mastoid cells. Dr. Barnhill does not believe it is ever wise, unless we have more positive evidence than is usual, to say to the patient that the only chance for his recovery is through operation. Patients get well that we thought would die without operation; and if we tell them there are absolutely no chances of recovery, and they afterward fall into the hands of quacks who treat them until such unexpected recovery takes place, they do the profession harm, for they are examples of our failure to foretell the truth. It is wise to spread a greater knowledge of ear diseases. Other surgeons have been more energetic in teaching the public in this respect. When we have a case in hand, we should make explanations, perhaps exhibiting some cuttings. This method has acted as the greatest kind of persuasion to the patient, easily showing that what is commonly regarded as the ear is in reality only one small part of the hearing apparatus, and that when the disease once reaches the cells behind the ear, the drainage is very poor. If the patient sees the relation of the mastoid cells himself, he is much more ready to consent to surgery than he would otherwise be, because it must be clear to anyone who sees the arrangement of the middle ear, mastoid cells and other parts liable to become affected, that surgery is often the only rational means of relief and cure.

Dr. D. McAuliffe, New York, said that it takes one of great diagnostic ability to determine this question. There is something recognizable in the patient himself which guides a man, more than the local symptoms. The symptom complex generally put down is so rarely met with in the vast majority of cases that we have practically no guide to determine the time of operation. Tenderness from pain depends on the elasticity of the cortex of the mastoid. He finds that temperature is the best guide, and that generally a case will show some slight elevation of temperature after two weeks. Bulging of the posterior wall does not take place unless infection has occurred. If the forward march of the sepsis is not well marked, this bulging will be absent. In mild attacks of mastoiditis there are very few local symptoms, but when they recover without operation the hearing is impaired.

Dr. Otto T. Freer, Chicago, emphasized that bulging of the posterior wall of the external auditory meatus does not always indicate suppuration of the mastoid antrum or cells. These cavities may be intact while a deep subperiosteal abscess may be the cause of the prominence of the posterior wall. There may be enough bulging to entirely close the auditory canal and yet the pus may be situated externally under the periosteum and not in the mastoid cells.

Dr. H. E. Smyth, Bridgeport, Conn., said that the surgeon who is always radical, or the one who is always conservative, has little trouble in deciding when to operate, but the man who endeavors to be radical or conservative, according to the disease in the temporal bone as indicated by external signs, is constantly in a dilemma. The amount of disease is sometimes so at variance with the symptoms that there is marked damage within the bone with little evidence externally to call attention to the fact, and conversely, marked symptoms with little disease.

Dr. D. J. McDonald, New York City, reported a case and remarked that we are taught now to look out for this condition of hidden sepsis. In every epidemic of measles Dr. McDonald said he inspected the secretions. If we do our work in this thorough manner, we shall be the means of publishing the results of otology to the world.

Dr. D. A. Kuyk asked if exploratory mastoidectomy in private practice is ever justifiable unless one has a fair proportion of symptoms indicating mastoid trouble and can assert positively the existence of mastoiditis. At what moment in the cases reported would have been the most advantageous time for operation?

Dr. E. B. Dench, New York City, said that he makes no distinction between private practice and any other; if there is any doubt whether to go in or not, he goes in. He would rather see a doubtful mastoid from the inside than from the outside. He explains to the family that an exploratory operation is justifiable and that there is no danger in it. In all cases where he has made this explanation and told the family he might find nothing, he has never failed to find something to justify the operation and to make him sorry he did not operate twenty-four hours before. He spoke of a case twenty-four hours after acute inflammation of the middle ear developed, in which he did myringotomy, and two days afterward opened the mastoid for tenderness and pain. He found pus in the mastoid cells, had a culture made, and it proved to be pure streptococcus. Had it been allowed to continue it would have spread to the deeper structures. When in doubt, operate, with explanations to the patient and family.

TWO CASES OF OBJECTIVE AURAL TINNITUS DUE TO THE ACTION OF TUBO-PALATAL MUSCLES.*

WALTER A. WELLS, M.D.
WASHINGTON, D. C.

Subjective noises in the ear, loud, distressing, and of various description, buzzing, ringing, roaring, singing, steaming, whistling, is one of the most familiar symptoms encountered in the practice of otology.

These sounds are sometimes so loud and intense that the afflicted patient is led to think that bystanders can hear them as well as himself, and it not infrequently happens that the physician is asked if he also can not hear the noise which the patient hears so distinctly.

But cognizant of their purely subjective character, the physician usually only laughs at the query.

It is worth while, however, to bear in mind that exceptionally this inquiry on the part of the patient is entirely justified and that if we put our ear close to his, we will discover that the sound, which we thought was heard only subjectively by the patient, may actually be heard objectively by another person.

Two kinds of objectively produced noises are distinguished:

1. Those of vascular origin, generally of a blowing, roaring or buzzing character, synchronous with the

---

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

pulse, and influenced by pressure on the large neighboring blood vessels.

2. Those of muscular origin in which the sound is usually described as clicking, snapping, or ticking, and is likened sometimes to the sound produced by the friction of the edges of two opposing finger-nails, or that of the snapping of the fingers, or the ticking of a clock or telegraph instrument, and even in exceptional instances, to that of the firing of a pistol.

The latter have no connection with the pulse beat, but are isochronous with movements of the palatal muscles, or of the drumhead, or both, and in a number of cases with spasmodic contractions also in the muscles of the face and neck.

Johannes Muller,[1] writing in 1837, seems to have been the first to have recognized the muscular origin of certain objective aural sounds, to all of which he ascribes one method of origin, viz: Contraction of the tensor tympani muscle.

Schwartz, Lucae,[2] Schappringer, Burkner, Lindet, Wolff and Kayser have reported cases which were thought by these authors to have a similar causation In 1862, Politzer,[4] and about the same time Luschka, working independently, came each to the conclusion that some cases of this type were to be explained by the action of the tubopalatal muscles, especially the contraction of the tensor palati. A few years later, in 1867, a case was reported by Boeck,[5] in which this author was able to make a postrhinoscopic examination at the time of the production of the sound. The patient presented a spasmodic, up-and-down movement of the larynx, and elevation of the palate accompanying the click, and according to Boeck[5] there could be seen also with each click a drawing forward of the anterior from the posterior wall of the eustachian tube. He considered that this thoroughly demonstrated the Politzer theory of a contraction of the tensor palati. Leudet,[6] in 1869, reported a case in which the clicking sound was accompanied with a movement of the drumhead as well as of the palate; and there was also a simultaneous, spasmodic movement about the eyebrow and in the suprahyoid region

In 1873, Kupper[7] had a similar case, but without the movements in the drumhead, in which pressure on the tongue would cause the clicking to cease

These were cases of involuntary clicking in the ear In 1879, Dr. S M. Burnett[8] of Washington reported a case of voluntary clicking, and the only other case besides Boeck's,[5] so far as I have been able to discover, in which a description is given of the postrhinoscopic appearances at the time of the clicking.

Dr Burnett's[8] case was also examined postrhinoscopically by Dr. Franck Hyatt, and the result of their examination, in which they agreed, was quite different from the above-mentioned case of Boeck.[6] "During the contractions," writes Burnett, "the anterior wall of the pharyngeal orifice remains stationary, while the posterior is moved obliquely forward and upward across the mouth of the tube, the edge sometimes reaching the anterior border and completely closing it, but usually going only about two-thirds the distance across. The uvula is at the same time drawn upward."

It has been my good fortune to meet with two of the class of objectively perceived clicking in the ears within a short time of one another, representing, respectively, the involuntary and voluntary type, in each of which it was possible to make a very satisfactory examination of the mouth of the eustachian tube during the production of the sound.

CASE 1.—The first case, a young man aged 24, was referred to me Nov. 15, 1903, by Dr. S. M. Burnett, who called my attention to an article in which he had reported the case of a voluntary objective clicking already mentioned. He wished that I should make an investigation of this case, with the view to finding any nose or throat lesion which might be responsible for the disorder.

History—The patient, apart from his being nervous and anxious about the present affection almost to the point of neurasthenia, presented the appearance of being in good general health. For the past two years he had been subject to a loud clicking sound in both ears, which of late had become louder and more frequent, and very distressing. The clicking, which is likened to the snapping of the finger, occurs generally in quickly succeeding waves of from 10 to 20 at a time, and at the rate of about 60 a minute. The noises are more persistent when the patient is tired and exhausted, while during periods of quiet and restfulness he is nearly free of them. Swallowing or even deep breathing will, however, excite the clicking at any time.

The noise in the ears is always accompanied by an up-and-down movement of the larynx, which keeps exact time with the clicking, and sometimes the larynx movement will be in evidence unaccompanied by the aural sounds

The patient called attention to two other symptoms which he had noticed. One that when he opens his mouth wide he has a sense of grinding at the point of articulation of the lower jaw, and the other that the act of opening his mouth wide in yawning is accompanied by the ejection of saliva in little jets or spurts

Examination —On examination it was found that a distinct clicking or snapping sound could be heard at a distance of about twelve inches from the ear, which was isochronous with the up and down movements of the larynx. This sound could also be heard in front of the mouth.

The eardrums were a little retracted, but otherwise appeared normal and did not show any movement The watch could not be heard farther than half an inch on either side

On looking into the throat it was seen that the muscles of the pharynx and palate were involved in an almost continuous clonic spasm, which accompanied the up and down movement of the larynx and was isochronous with the clicking noise in the ears The spasm consisted chiefly in a jerky, somewhat violent muscular movement, causing an approach toward the middle of the posterior pillars of the palate, together with a more or less elevation of the palate—similar to the movement which is seen to take place in the act of vomiting

A view of the nasopharynx showed that the mouth of the eustachian tubes was also involved in these movements in the sense that at each spasm the posterior lower lip moved forward and upward in such a way as to greatly narrow the opening of the tube, and the angle which appears in the image as an approximate right angle, looking forward and formed by the upper and lower part of the eustachian eminence, becomes narrowed into an extremely acute angle, or is entirely obliterated by the elevation of its inferior border

The posterior extremities of the turbinates were somewhat enlarged, and there was inspissated mucus to be seen in the postnasal space and about the orifice of the tubes

The pharynx presented the picture of the so-called lateral pharyngitis. The tonsils were moderately hypertrophied.

Treatment.—The treatment consisted at first in overcoming these hypertrophic conditions in the nose and throat, with a hope that reflexly they might beneficially influence the muscular contractions. The ears were also politzerized. This line of treatment was absolutely without any effect on the symptoms, although the hearing improved moderately.

Later, under catheterization and the employment of the eustachian bougie, swabbing of the postnasal space, and applications of astringent remedies directed to the eustachian orifice, the conditions appeared to improve slightly.

After the patient had been under observation about two months he left the city. I heard from him once, a few weeks after leaving, stating that the clicking in his ears was better.

Case 2.—A young lady consulted me in regard to a slight feeling of fullness in the right ear, and a voluntary clicking which she said had existed as far back as she could remember. The sounds could be produced by a movement of the throat similar to that made in the act of yawning. The clicking in this case was not so loud as in the former, but could be distinctly perceived objectively with the ear held four or five inches from the patient's.

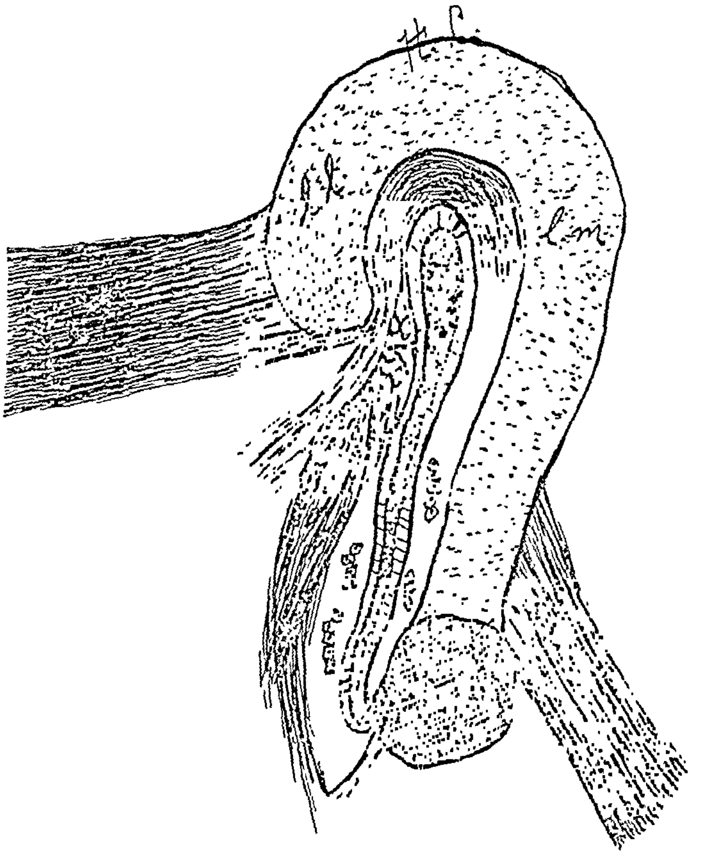

Fig. 1.—Cross section of the eustachian tube near its pharyngeal extremity. Represented as in its ordinary state with its walls in apposition, except at the upper part. H. C., hook cartilage; l. m., lamina medialis; t. p., spheno-salpingo-staphylinus muscle (tensor palati); s. p., salpingo-pharyngeus muscle (palato-pharyngeus); l. p., petro-salpingo-staphylinus muscle (levator palati) in cross section.

Examination.—The hearing was normal; the membranes were each slightly opaque, and the right a little retracted; otherwise normal. Nothing abnormal in the condition of the mucous membrane was to be discovered in the examination of the nasal fossa, the postnasal space or the fauces. The contractions which took place in the throat at the time of the production of the clicking were far less violent than those noted in the other case. The movements which were chiefly observed were slight, jerky contractions of the posterior pillars, to which was occasionally added an elevation of the palate, but the latter movement was not at all necessary to the production of the clicking sounds, which were observed to be precisely isochronous, with the contractions of the palatopharyngeus.

Examination of the postnasal space showed no drawing away of the anterior wall from the posterior; there occurred the upward and forwar [illegible]vement of the posterior lip seen in the other case, but this was not a constant accompaniment of the sounds, taking place only when the palate was elevated. The only other movement was a scarcely visible fibrillary twitching of the inferior angle of the orifice at the moment of the contraction of the pillars.

Treatment.—The eustachian bougie was introduced into the tube and a postrhinoscopic examination confirmed the fact of its being in place. This procedure seemed to have little or no influence on the production of the sounds.

Two or three weeks' treatment, consisting chiefly in the use of the catheter, the bougie, or the application of astringents to the mouth of the tube, were unsatisfactory in their results. Sometimes immediately after the treatment the sounds would not be so loud, but this improvement was not permanent.

In both of the cases here related, the conclusion is obvious, that the sounds produced in the ear were due to a contraction of certain muscles of the pharynx and palate connected with the eustachian tubes, in the one case, loud snapping noises heard in both ears and associated with involuntary choreiform movements of the muscles on the outside of the throat as well as inside; in the other, a clicking sound, voluntarily produced, confined to the right side, only audible to the examiner with the ear placed close to that of the patient's or by the use of the stethoscope.

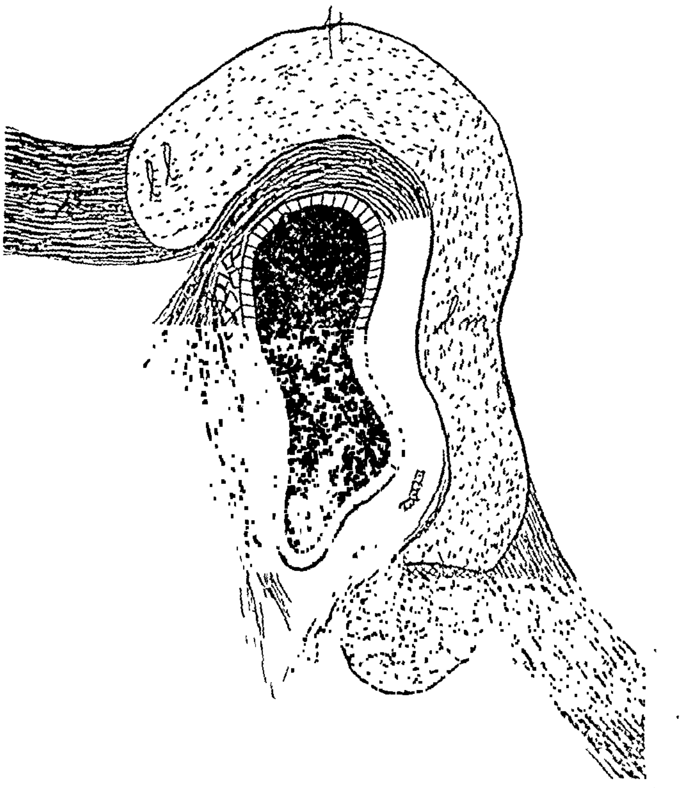

Fig. 2.—Same, showing supposed effect of tensor palati and palato-pharyngeus muscles in dilating the orifice of the tube.

There was in neither case any visible movement of the drum membranes, and the sounds kept perfect time with the contractions observed in the throat. The only question is as to the mechanism which gives rise to the sounds described.

There are three muscles connected with the pharyngeal extremity of the eustachian tube (Fig. 1): 1. The tensor-palati (spheno-salpingo-staphylinus), which is attached to the anterior or fibrous wall of the tube, and whose function it must be to open or dilate the tube by drawing the anterior wall forward (Fig. 2).

2. The levator palati, which lies along the lower part of the posterior or cartilaginous wall, and whose function is disputed, but is generally believed to be that of making the tube more patent by the shortening of its long diameter which results from a contraction of the body of the muscle (Fig. 3).

3. The salpingopharyngeus, a slip which passes from the palatopharyngeus to be inserted into the posterior wall of the tube at its lower extremity. This little muscle is generally overlooked, but is said by some physiologists to take part also in the opening of the tube.

The explanation which Politzer[5] and Luschka have offered contemporaneously, as already mentioned, to account for these snapping noises, is that it is due to the action of the tensor palati drawing the anterior from the posterior lip of the eustachian tube. This explanation has been generally accepted by other authors who have reported cases (Kaufman,[9] Brandeis,[10] Gerould,[11] Goldflam and Meyerson,[12] Schwartze), though the cause has been here and there attributed to contractions of the levator palati.[13]

That the noise is produced by sudden separation of the moist agglutinated walls of the eustachian tube would seem to be the only satisfactory hypothesis, and while the contraction of the tensor palati may be the chief muscle concerned in the action in some cases, the constant, isochronous contractions of the palatopharyngeus observed in my two cases, in one of which generally unattended with any palatal contraction, would seem to prove that the salpingopharyngeus should also be considered as sharing in the causation of the sounds.

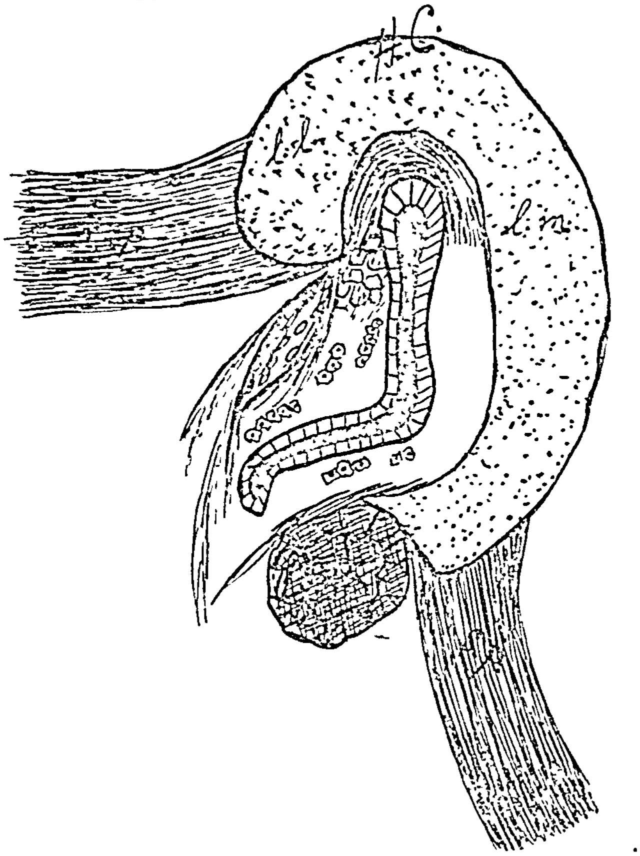

Fig. 3.—Same, illustrating possible effect of levator palati (l. p.), supposing it to have the function of closing the tube—the two other muscles conceded to be dilators.

The impression which we gathered from the study of the nasopharynx at the time of the contraction was that the action of the levator palati was rather to close than to open the mouth, as evidenced by the upward and forward movement of the lower posterior lip to the anterior lip, precisely as in the case described by Dr. Burnett.

Instead of all three of the muscles being engaged to open the tube, is it not reasonable to suppose that one of them should have the function of closing it?

If this be so, we may then consider both the tensor palati and the salpingopharyngeus as acting in antagonism to the levator palati, both tending to open the tube, the former by drawing the anterior wall forward, and the latter by pulling the lower part of the inferior wall backward and downward.

The action of either one or both might be concerned in the production of the clicking tinnitus.

The number of cases of clicking tinnitus which has been reported—exclusive of those due to contraction of the tensor tympani—is not large. Cases of the voluntary type have been reported by Lucae,[2] Politzer,[14] Delstance,[15] S. M. Burnett,[8] Orne-Green, Bremen.[16] Cases of involuntary clicking by Kupper,[7] Leudet,[6] C. H. Burnett,[17] Urbantschitch,[18] Mermod,[19] Szenes,[13] Brandeis,[10] while Baker,[20] Shield,[21] Schwager[22] and Kaufman[9] have reported cases of involuntary clicking that were, however, at the same time in a great measure under the control of the patient's will.

ETIOLOGY.

So far as I have been able to make out by review of the literature, neither age, sex nor race have any particular influence in the etiology of the affection.

Many of the cases were spoken of as having a very decided, nervous disposition, and in two or three instances (it may have been merely a coincidence) a history was obtained of a fall or blow on the head. A case reported by Shield[21] had been in earlier life a stammerer.

Urbantschitch's[18] case had formerly been a subject of general chorea, and he looked on the contraction of the throat muscles as a sort of choreic manifestation.

In several cases the patient presented spasmodic movement of other muscles than those of the palate or pharynx. In Kupper's[7] case, there took place an elevation of the root of the tongue and a contraction of the muscles about the mouth; in Leudet's[7] case, there was a spasm of the eyebrow and of the mylohyoid and digastric muscles; in Boek's[5] case, an up-and-down movement of the larynx, as was observed in the case reported here.

TREATMENT.

So far as treatment is concerned, no deduction of any value can be drawn from the literature of the subject.

The administration of nervines and tonic remedies, change of air, sea voyage, the discontinuance of any confining or strenuous occupation, the treatment of any possibly existing nose or throat lesions, and a few other such usual commonplaces predicated on general principles have been advised by those who have written on the subject, and if the indication exists, one will, of course, not neglect such remedies; but, after all, it has to be admitted with regard to the objective form of tinnitus, as with the subjective, its prognosis is bad, and its treatment unsatisfactory.

DISCUSSION.

DR. W. S. BRYANT, New York City, said that all cases of tinnitus with the muscular basis have an important neurotic element which is responsible for keeping up the symptoms. A certain per cent. of these cases have impaired action of the pharyngeal muscles resulting in some unusual symptom which the patients brood over. As long as their minds are fixed on this, it is almost impossible to get a cure unless their hypochondriachal attitude can be changed. Local treatment does no good unless the mental attitude is changed at the same time. Very good results are obtained from the use of electricity in the neighboring regions, which probably helped the muscles and nervous mechanism. At any rate it pleases the patients and gives them confidence in the physician.

DR. C. R. HOLMES, Cincinnati, said that he had had but one typical case several years ago, where there was a clicking audible at a distance of several feet. He examined the case carefully with the mirror and each click was associated with a rhythmic contraction of the drum. The patient was under observation for a week or ten days for some other trouble and he called in a number of his colleagues to see it. The clicking was intermittent and would come on after nervous excitement or after eating a heavy meal, lasting from a few minutes to an hour or two.

OSMOLOGY AND PHARMACODYNAMICS.*

HEINRICH STERN, M.D.

NEW YORK CITY.

Osmology is usually defined as the science treating of the osmotic states of the body fluids. However, as the osmotic processes in a liquid in a great measure reflect also its other physical conditions, this fact should be embraced in an adequate definition. Osmology, hence, may be spoken of as the knowledge concerning the physical conditions of and in the body fluids. This broader conception is adhered to throughout this paper.

The health of an organism depends on the existence and maintenance of its osmotic equilibrium. By osmotic equilibrium I understand that inter-relation of the physical conditions of the various body fluids—molecular concentration, osmotic concentration,[1] tension and dissociation—which is essential for the normal performance of the vital processes. This inter-relation does not consist in the equality, but in the physiologic dissimilarity of the osmotic conditions in the different fluids. In certain pathologic states, the fluids in the organism tend to equimolecular or equiosmotic concentration; the normal processes of life, however, are possible only so long as this uniformity is not established.[2]

It is the special office of the organs of secretion and excretion to maintain the osmotic equilibrium. A structural alteration of one or more of these organs, causing functional impairment, is liable to result in serious disturbance of the osmotic equilibrium. The functional impairment of such an organ is demonstrable by the altered osmotic tension of its secretion or excretion, which again may be an indication of the modified osmotic conditions in the blood. Normally, the secreting organs withdraw from the blood a certain amount of water in which are dissolved specifically proportionate quantities of inorganic and organic salts. The diseased emunctory is unable to cope with the secretion work, the absolute amount of water and salts withdrawn by it from blood and tissues falls short of that which it eliminates when functionating properly. Furthermore, the amount of water and solids secreted or excreted by a diseased organ may be in disproportion, that is, while the absolute amounts of both are diminished, the relative water or salt output may be still further reduced. The disturbance of the osmotic equilibrium between the body fluids and between the blood and the secretion or excretion progresses or regresses as a rule at the same rate as the structural changes in the parenchymatous tissues increase or subside.[3]

While the intrasystemic osmotic disturbances may be but rarely determinable by our present clinical means, the disturbed osmotic equilibrium between blood and secretion is soon demonstrated by simple physical methods. The degree of osmotic disequilibrium between blood and secretion is both an indicator of the intensity and the course of the pathologic process in the parenchymatous structures as well as of the influence of the therapeutic measure exerted on it. If there is a tendency to restoration of the osmotic balance, that is, if the insufficiency of the organ is gradually giving way to physiologic activity, the plan of treatment should be further pursued. If, on the other hand, improvement does not ensue after a protracted period, or if equilibration becomes still more distant, the therapeutic measures, as maintained by Zikel[4] should be at once replaced by more rational ones.

Pharmacologic action is not of an exclusive chemical nature. This fact, although not pronounced in so many words, was already recognized by Schmiedeberg[5] when he says that the molecular processes, as distinguished from those occurring between the atoms, should be taken into consideration when defining "chemical action." Further proof of his conception of "physical action" is furnished by his explanation of the non-toxic action of distilled water after its ingestion.

It is not often possible to distinguish between chemical and physical action; where the one ceases and the other begins is indistinguishable in almost every instance. We may assume even that the action of a great number of substances on the living cells is both of a chemical and physical nature. Purely chemical or purely physical action is exhibited by comparatively few remedial agents. In so far, however, as one or the other mode of action predominates, we may differentiate between substances acting chemically and such that will display physical activity.

---

* Read in the Section on Pharmacology of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

[1] While "molecular concentration" indicates the number of moles (gram-molecules) contained in a liter of fluid irrespective of an eventual dissociation, "osmotic concentration" as suggested by Hamburger (*Osmostischer Druck und Ionenlehre*, 1902) is the expression of that concentration indicating the total amount of molecules + ions contained in a liter of the physiologic or pathologic fluid.

[2] Complete uniformity of all partial osmotic tensions supervenes at no time and nowhere in the organism. Such uniformity would result in the cessation of the tissue currents, but there is absolute proof that such cessation can never occur; in the dead human organism even these constant currents may be yet demonstrated. (Zikel.)

[3] *In certain phases of degenerative processes* the insufficiency of an organ may yet for some time be averted by its unaffected cells; in case even that an organ has entirely ceased to functionate, another organ or set of organs may display vicarious activity, so that for the time being osmotic disturbances either do not ensue at all or are kept at a minimum.

[4] Zikel: Klinische Osmologie, 1902.

[5] Schmiedeberg: Grundriss der Arzneimittellehre, 1883.

Again, pharmacologic action is determined by the constitution of the cells or cell-complex reacted on. Thus, a substance may not cause any reaction in the protoplasmic molecule—it may neither stimulate nor depress; or it may influence cellular function by calling forth chemical alterations of the cellular material, the specific composition of which invited chemical reaction; or it may modify tissue function by changing the molecular constitution of the intracellular or extracellular fluids. Whatever the mode of the action of a substance on living protoplasm may be its influence is one of a modifier only, that is, it may excite and increase or reduce and suppress functional activity, but it does not occasion any new function.

Ever since the advent of solidar pathology and the doctrines originating therefrom, the chemical nature of pharmacologic action was the one principally studied. Although the laws of endosmosis and exosmosis were known then, but few pharmacologists devoted sufficient attention to the physical side of pharmacologic action. And yet, the physical action of drugs, the salt action in the more limited sense, is so much simpler, is so much easier of comprehension than the complicated, only to the most rudimentary degree understood chemical drug action. I can not offer an explanation for this historical phenomenon, but it occurs to me that much could have been accomplished in the physical domain of pharmacology even before the rise of Van't Hoff, Arrhenius and Korányi.

By physical pharmacologic action I understand that influence which is exerted on the living cell by directly modifying the molecular constitution of the intracellular or extracellular fluids without synchronous alteration of the chemical structure of the protoplasm.

In the same sense in which osmology is the science treating of the physical conditions of and in the body fluids, osmotherapy is that mode of treatment, the ultimate aim of which is re-establishment of the normal physical conditions, the osmotic equilibrium. In its last instance, osmotherapy regulates the electrical conditions in the body fluids. Osmotherapy produces physical stimulation or depression by withdrawing, supplying or dissociating molecules; physical stimulation, again, is a mediate result of increased physical depression, that of diminished electrical conductivity of the intercellular or intracellular fluids.[6]

The remedial agents whose foremost action is the physical one, I designate as "equilibrants." They may be divided into four great classes:

1. Agents exerting specific localized activity; agents influencing the secretory and excretory functions of the diseased organ by transitory or permanent restoration of normal semi-permeability.

2. Agents regulating the perverted osmotic conditions of a certain body fluid, or maintaining a general osmotic equilibrium for the time being.

3. Agents whose principal action depends on their ions; agents which influence the electrical conditions in the system.

4. Agents with combined action; agents exhibiting any two or all three actions enumerated.

These equilibrants are all recognized therapeutic agents; each group has had its representatives in the armamentarium of the practitioner who, guided by a higher or lower degree of empiricism, only vaguely understanding their pharmacologic action, has virtually always employed them.

Under equilibrants with specific localized action I comprise those agents which in the face of impaired permeability of an organ, without being absorbed or, if so, without producing important systemic effects, cause it to functionate more or less normally. Stimulating the secretory or excretory activity without entering into or changing the chemical constitution of the irritated cells and not withdrawing by its own mediate action the components of the secretion or excretion from the blood, the paramount effect of these agents seems to be exerted on the impaired semi-permeability. The outpouring of the secretions following the administration of these substances is considered to be due to stimulation of the sympathetic, or to some other, mostly nervous cause. This may be true; still, the drug action has to be looked on as a purely physical one, as all elements of the secreting cells touched by the drug are more or less affected at the same time; as in certain cases the application of drugs tends to permanent improvement of the secreting power, and as artificial irritation is in vain unless all conditions essential to the secretory process are fulfilled. Moreover, if a secreting organ is in an atrophying state, its nerves also share in the degenerating process.

Among the equilibrants belonging to this group are the stomachics of condimental nature. This administration of a preparation of *Zingiber officinale*, for instance, in a case of chronic gastric blennosis of the second or of the beginning third degree frequently causes correction or augmentation of the gastric juice; it tends to equilibrize the osmotic conditions between the blood and the gastric secretion which is proved by the augmented production of hydrochloric acid, or by the latter's occasional production *de novo*. The formation of hydrochloric acid depends on the improved permeability of the glandular membrane.[7] Medicaments of similar local action, irrespective of synchronous ganglionic irritation, I count among remedial agents whose paramount pharmacologic action is a physical one.

Agents regulating the altered osmotic conditions in a body fluid are the equilibrants *par excellence*. Such agents are water and salts. They mainly differ from the equilibrants with specific localized action in the fact that they themselves furnish the material by which the osmotic conditions are directly influenced.

The employment of the equilibrants of this group should be based on a minute study of the osmologic disease factors. It is not the introduction *per se* of the equilibrant by which the osmotic conditions are corrected. This is accomplished by the quantity of the equilibrant conforming exactly to the functional change. If, for instance, the pathologic, cryoscopically ascertained, osmotic pressure of a body fluid be subnormal to a certain degree, and if the deficiency is to be corrected by sodium chlorid, exactly the amounts of sodium chlorid necessary for the correction of the osmotic pressure are to be injected. Too little of the sodium chlorid may not effect any material alteration of the condition, too much of this salt may be followed by untoward phenomena.

---

[6] I do not consider the non-dissociated molecules of the same importance as the ions, between which the reactions occur with greater ease and rapidity than between the former. The majority of the physical pharmacologic reactions very likely occur between the ions.

[7] Gastric hydrochloric acid does not originate in the glandular cell, but in the glandular membrane. This, a semi-permeable membrane, is impervious to free chlorin ions, but permeable to the hydrogen ions, coming from the blood. A certain secretory irritation is essential for the production of hydrochloric acid. This irritation is called forth by the presence of free chlorin ions on the inner side of the gastric membrane. Stomachics, like those aforementioned, create conditions facilitating the passage of chlorin ions to the inner side of the gastric membrane.

The performance of cryoscopy is indispensable, when equilibrants of this category are to be employed. By its aid we are enabled to determine the osmotic alteration of the body fluid, the osmotherapeutic correction for its restoration, and the specific equilibrizing value of every osmotherapeutic agent.

The specific equilibrizing value of an equilibrant consists in the faculty of modifying a pathologic condition or a symptom by means of its purely physical properties, as molecular weight, dissociation and concentration.

In case two or more equilibrants are used in combination or alternately the osmotic partial pressure of each has to be taken into consideration.[8] According to Zikel[2] the concentrations of two specific injection-osmo remedies must be like the products from their molecular weights and the mutual dissociating coefficients.

Besides, the influence exerted by these equilibrants on the osmotic conditions *per se,* their dissociated parts, the ions, which are the conductors of electricity, may alter the electrical conditions in the organism. While there is no doubt that the mediate and individual action of the ions is of a chemical nature, their ability to conduct electricity is a purely physical property. The ions are conductors of ectogenous as well as of endogenous currents of electricity. Their ability to conduct the intrasystemically generated electricity stamps them as one of the most potent factors in the vital processes. It is evident that, if ionization is deficient, or if the electrolytes are interfered with by non-conductors,[9] the electrical conductivity of the body fluids, as I have shown elsewhere, will be diminished or entirely suspended. Among the equilibrants, hypotonic salt-solutions (or water) are often the most important, as first pointed out by me.[10]

Among the equilibrants with combined action, distilled water,. under certain conditions, stands at the first place. In cases of hypochlorhydria, on the basis of chronic gastric catarrh, occurring together with renal insufficiency, for instance, distilled water acts primarily as an irritant, casting off the degenerated epithelium and establishing a more normal state of partly permeability of the gastric membrane. Subsequently, when lodged in the intestines, it exhibits its other equilibrizing qualities by withdrawing salts from the organism, by diminishing molecular concentration of the serum and by permitting or effecting increased ionization.

Osmotherapy is as yet in its very infancy. Of its rationale—if the premises, the theories of osmosis and dissociation be well founded—there is not the shadow of a doubt. But how well are these conceptions founded? Do we not conceive of Nature and her forces a little differently every few years? Will these conceptions endure sufficiently long to impress their mark on all the branches of medicine, as the bacteria have done?

I have briefly sketched the relation of osmology to pharmacodynamics in the light in which I see it. The picture, I know, is incomplete, and, perhaps, too tersely drawn in some respects. Succinctness, however, was compulsory on this occasion.

---

[8] Osmotic partial pressure is the osmotic pressure of an individual dissolved substance in a solution of mixed substances. The osmotic pressure of a dissolved substance mixture is equal to the sum of the partial pressures of the individual substances.

SOME PROBLEMS OF PRESBYOPIA.*

GEORGE M. GOULD, M.D.,
PHILADELPHIA.

When I began practice I did as I had been taught regarding the correction of presbyopia. Text-books, teachers, and general custom agreed that presbyopia began sometime after forty, and that no mydriatic was needed in such patients. There was a rough rule wandering about that plus spherical lenses of one diopter were needed in forty-five-year-old patients, twos at fifty, threes at sixty. This was about the time of the "Punch, Brother, Punch with care, a blue slip ticket for a five-cent fare, etc." Actual dealing with presbyopic patients soon brought me up sharp. Rules like those of the street car conductors would not work out in the oculist's office. If any rules at all were admissible they had to be of a different kind from those of the text-books; in some ways far more definite, in others more indefinite. Some of these cautions I have brought to clearness are as follows:

1. In oncoming and progressive presbyopia, cycloplegia is generally necessary to obtain the static refraction on which the presbyopic correction is based.

Precisely in eyes whose accommodation powers is being narrowed and lessened is the mydriatic most needed in order that eyestrain may not be increased by the close limits in which function is being compressed. When there is youth and a high range of accommodation the refractive error may not produce the injury taking place in the presbyopic. This is a truth so self-evident that it is astonishing to find it utterly ignored in Europe and too commonly ignored in our country.

The slightest misplacing of the axis of astigmatism, the failure to get the accurate amount of the error of refraction, the least imprecision in correcting the slight anisometropia, insure more trouble in the presbyopically lamed eyes than in others with plasticity and with activity of neutralizing or compensating powers. If there are symptoms of eyestrain, and especially if accompanied with any doubts in my mind as to accuracy, I do not hesitate to use a mydriatic up to the ages of fifty-five or sixty. I think almost all patients up to fifty should have it. I mean homatropin and cocain, and instilled in the office.

Discrimination as to those with latent or manifest glaucomic tendencies is, of course, demanded. The individual expertness of the oculist must also be considered. The art of refraction requires a skill, a judgment and a delicacy of perception, as great and rare as in any other calling, greater, I believe, than in surgical or inflammatory conditions. A highly exceptional mastery of the art may succeed in estimating the error of refraction without a mydriatic when others would fail. None may safely lay claim to such ability. None, at least, may safely trust himself in its habitual employment. Easy going assumption of it is another phasing of the characteristics which have duped us since proverbs and folk-tales and the ophthalmometter were invented.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

2. The age at which presbyopic correction should first be given depends on the pre-existing refractive error.

The old rules as to forty-five, etc., are nonsense. If the patient has two diopters of hyperopia, the presbyopic correction will be needed much earlier than if he is emmetropic. If he has myopia, the necessity will arise later, as is well understood. But astigmatism creates a greater indefiniteness, and especially if it is unequal, or if unsymmetric. Anisometropia further complicates all rules and makes them still more indefinite. The onset of troublesome presbyopia also depends on whether the ametropia has been corrected or not for years previous.

3. The correction of the presbyopic error of one or both eyes is often dependent on the existence in one eye of amblyopia from disuse.

This exclusion of one eye from function always brings most difficult problems. If of high degree and of long standing it may not be possible to get reaction or to stimulate the lost power into function. As a rule I believe in saving partially ruined eyes, and it is possible to do so more often than has been supposed. Such eyes exist far more frequently than text books and teachers tell us about. In some rare cases at the presbyopic age the attempt to save the eye and bring it into function is not only possible, but will produce most decided rebellion on the part of eye and brain. These "hurt eyes," with stippled maculas which let you stare at them, and which so plainly show neglect and sin, both lay and medical, are daily visitors to the oculist's office, and they make his hair gray sooner than should be.

4. Less accommodation in one eye than in the other may condition the amount of the presbyopic correction.

This inequality of function may be the result of anisometropia, of right-eyedness or left-eyedness, of a peculiarity of occupation, of monocular disease or injury, of heterophoria, etc. It is of more frequency than is suspected, and causes much ill-success in the correction of presbyopia.

5. The onset of presbyopia demanding correction may be delayed beyond the usual age by hypertrophied accommodation.

This abnormalism of excessive accommodation is the result of lack of presbyopic lenses, with the resultant over-function of the ciliary muscle and abnormally retained elasticity of the lens. Excessive use of any organ, or abnormally prolonged use, produces disease. That of the accommodation in presbyopia causes eyestrain and all of its reflexes. The eye itself or the organs which bear the brunt of the derouted reflexes must suffer. I have heard of one oculist who attempted for many years to postpone presbyopia requiring correction into old age. That is a human vivisection experiment that would be somewhat interesting to science, but which I should be far from wishing to try in my own case. We see daily the injury and the suffering it causes in old people who indulge in the puerile vanity of ability to "read without glasses." The result is that they do not read much, their little intellect goes to seed, and the little reading they do produces disease.

6. The correction of presbyopia at an early or late age, and the high or low degree of the error depends on the amount of near work demanded of the eyes.

In nonreading farmers, workmen, seamen, etc., the correction is not required to be made at so early an age, nor perhaps in so high a degree as in sewingwomen, literary people, engravers, etc. A hurried test may also result in a too low correction, because the accommodation by a moment's intense effort may prefer a lower lens than would be required in more prolonged use of the eyes at near range.

7. Presbyopes who deceive the oculist as to their age may suffer if he has not been alert minded to detect the error.

One must be on his guard in treating "women of doubtful age."

8. The peculiarity of the habitual occupation may necessitate a higher and earlier correction than is usual.

Embroidering, "sewing on black," engraving, watchmaking, measuring in sixty-fourths of an inch, etc., are kinds of employment that make inordinate demands on the accommodation.

9. The light, its quality, power, etc., must also be inquired into.

If a patient works all day by artificial light, or by poor daylight, in darkened rooms, if the angle at which even a good light strikes the work is not right, eyestrain is sure to result. If after a long day of strain, under these hurtful conditions, reading, sewing, etc., are continued at home, and again perhaps, with bad lights, the results must be deplorable.

10. The position of the body and head in sewing, reading, or other near work, may be harmful to the eyes and the general health.

If the book, sewing material, writing, etc., is placed in the lap, or in such a position that the head is bent over, the spine curved, and the chest flattened, the injury to the patient's eyes is almost certain because of nonillumination of the page, paper, etc., and also because of the improper position of the eyes and head. The health generally must be harmed by the compressed condition of the pelvic organs and the lungs, poor respiration, etc.

Bookkeepers, etc., should stand at their work as much as they may, and chairs at desks should be low, the desk high, the writing leaf inclined, the axis of vision as nearly as may be perpendicular to the plane of work and of the spectacle lenses. The single disadvantage of the bifocal lenses is that they compel the axis of vision to be inclined downward. For this reason they should be set high before the eyes, and the habit advised of "chin-up." Book rests, book holders, etc., should be encouraged. In my boyhood "sewing-birds" screwed to tables were common. They were most excellent devices.

11. The state of the general health, the preserved vitality, the vigor of will and of body, will also condition the early or high correction.

A flaccid muscular tone, anemia, denutrition, care and worry, a melancholic or pessimistic disposition or philosophy of life, may not be entirely overlooked. Patients so handicapped require a fuller or earlier presbyopic correction than those who are more vigorous. Their innervational power is lessened and sometimes nothing the oculist can do will enable them to carry on severe near work when presbyopia doubles their strain.

12. Failure to cure the reflexes of eyestrain may be due to the want of bifocals.

Two separate pairs of lenses can not correct eyestrain as do the double lenses. With a distant pair only, there is an hour or more of strain every day in eating meals. There is also forgetfulness to change or indifference to the need of it, lenses are not repaired, are misplaced or lost, etc. The one disadvantage of bifocal lenses is counterbalanced a hundred times by the manifest benefits over the distant and near glasses made separate.

13. Eyeglasses being more prone to maladjustment than spectacles may be the cause of failure to bring relief of the symptoms or sequels of presbyopic eyestrain.

There are few noses capable of retaining bifocal eyeglasses in a correct position. The more expert the optician the more the attempt may be tried. This is especially true if the patient can consult the fitter at least once a month. Patients who by reason of living at a distance can not do so should not be allowed bifocal eyeglasses under any circumstances. To those with high degrees of astigmatism they must also be forbidden, except for one nose in ten thousand. Vanity causes a deal of suffering both to patient and oculist. It may prevent the patient wearing any glasses, and thus double the local and systemic reflexes. When, as usual, vanity demands eyeglasses, and the result is certain to prove bad, my custom is to tell the patient to consult another oculist. No greater ill fortune could happen to your rival than to have the patient go to him! And there is no better punishment for vanity than eyeglasses, unless it be the rest cure.

14. Premature presbyopia, or paresis of the accommodation, may occur years before the usual age, and explain failure to relieve symptoms when none of the preceding causes will do so.

The patient may have contracted a chronic habit of reading at too great a distance, and the presbyopic lenses ordered may force him to hold the page or sit at writing at a shorter distance than is comfortable or perhaps best.

This is especially true if there is exophoria or insufficient adduction power. If this is so, the adduction should be increased until comfort is secured, habitual reading or writing at, say, 20 inches may itself be a source of eyestrain.

16. The patient may have supernormal adduction power and the presbyopic lenses ordered may force him to read or write at too short a distance.

In this case, at least until the adduction lessens, the too weak lenses may cause discomfort.

17. The symptoms may not be due to presbyopia, nor to any eyestrain, but to systemic disease.

Every oculist has had many patients whose symptoms had been treated by glasses alone, or whose ocular muscles had been "clipped," when all the time there was concealed or unknown systemic disease, e. g., nephritis, diabetes, anemia, etc., or some morbid result of bad dietetic or other habits, which were the only or chief causes of trouble. This does not in the least excuse those wonderful oculists who find that all eyestrain symptoms and reflexes are due to systemic conditions. That is a good way to please the referer of cases, and to conceal inaccurate refraction. But it is not the best way to practice ophthalmology.

The preceding rules are, in fact, non-rules: they are in truth, cautions to have no rules in correcting presbyopia. Every case is exceptional and individual and requires a freedom of the mind from bias or prejudice of any kind. Precision in estimating the conditions, infinite patience, delicacy, and conscientiousness, in hunting out the individual variation there before one, and inexhaustible ingenuity in meeting all the varied and varying phases and factors, are the prerequisites.

There is but one invariable rule: Have no rule. Rules are the makeshifts of the lazy and unintelligent. The cunning rely on them, forgetful that cunning is really stupidity. Optical machines are often rules made into iron rods, scales and wheels. They may be of service if used not as dictators but as slight helpers, in the hands of the intelligent and guiding machinist, but they may serve as the excuse and ruin of those who rely on them to the exclusion of intelligence and diagnostic skill.

Any number of cases could be epitomized, illustrating the foregoing suggestions. I shall content myself with but few, because in every oculist's memory there doubtless arises plenty of examples.

Case 1.—A lawyer who carried on a tremendous amount of eye work had an enormously high and complicated compound hyperopic astigmatism. Despite a perfect correction of his ametropia by capable and good oculists, and despite the best treatment by general physicians, his dyspepsia persisted. In obedience to his demand his oculists had allowed him to wear bifocal eyeglasses. A difference of five degrees or ten degrees in his astigmatic axes, inevitably caused by maladjusted eyeglasses, rendered his ametropic correction worse than useless. They failed to cure their patient because they did not demand spectacles.

Case 2.—A woman of thirty-nine had sick headache which reappeared every few weeks despite my best correction of her low compound hyperopic astigmatism. I had three times gone over my work and found no change in her glasses was to be made. I feared I had what I had always been looking for—a typical migraine which I could not cure with glasses. Inquiry elicited the fact that the woman habitually did an enormous amount of literary work. I ordered presbyopic correction and bifocal spectacles to be worn constantly and the "migraine" has never shown a sign of itself since.

Case 3.—A healthy, clear-headed intellectual man was given two pairs of spectacles for his myopic astigmatism, a stronger or higher correction for use at the theater, driving, etc., a weaker correction for reading and daily or constant use. For a year his wife and daughter observed, without telling him, that whenever he wore the strong, or accommodation-exciting glasses he "caught cold" with coryza, hoarseness, etc., which at once disappeared when the weaker lenses were used. He used the stronger ones but few times a year. When certain of the strange coincidence his wife told her husband. In the past ten years the cold has been produced in this way, a hundred or more times. Now if his weaker glasses get "crooked," or maladjusted, miscorrecting his axis of astigmatism by a few degrees, his cold promptly appears, to vanish in an hour after a visit to the optician.

Case 4.—A gentleman of fifty years of age had consulted many of the most famous oculists because of severe and frequently recurring subconjunctival hemorrhages. Some of these had refracted his eyes, some had not, but all had followed a not uncommon custom of charging such symptoms to gout. None had found any error of refraction, except, of course, a couple of diopters of presbyopia. By the most competent authority his eyes had been pronounced mathematically emmetropic and perfect. None, of course, had used a cycloplegic. With paralyzed accommodation I found 0.25D of simple myopic astigmatism axis 180 degrees in each eye. For several years he has had no hemorrhages and by his glasses he has had also such relief from other cerebral symptoms that he has had heavy iron spectacles made for use in his bath, so that he may not be without lenses for a minute.

DISCUSSION.

Dr. Robert L. Randolph, Baltimore, said that he is surprised to find how often it is necessary to use homatropin in order to discover the astigmatism which is frequently responsible for the discomfort in these cases. The presbyopic condition, no matter how advanced, has never deterred him from the use of homatropin where there was the slightest doubt in mind as to the true condition of the refraction and he called attention to the great convenience of the cocain-homatropin discs. He usually employs two of these in each eye at intervals of twenty minutes, and an hour from the time when the first disc is introduced into the conjunctival sac the patient is ready for the examination. Results in his experience in both old and young do not differ from the results obtained when either atropin or homatropin has been used. The fact that the desired result is obtained quickly is a distinct advantage as lessening the chance of high tension, and the fact, too, that the effect is promptly nullified by eserin is an additional advantage for obvious reasons. It is no uncommon thing for a patient to be able to use the eyes for close work within two or three hours after the instillation of the eserin. It is his habit to wait till the patient has experienced decided twitchings of the lids before allowing him to leave the office. These discs can be best used when put up in gelatin capsules (No. 2 size). The smaller half of the capsule is taken off and the disc can be emptied right into the conjunctival sac, where it remains. Four capsules, each containing a disc, are used for each patient.

DR. G. C. SAVAGE, Nashville, Tenn., said that a strong ciliary muscle means a small nervous impulse and late presbyopia. The presence of a strong ciliary muscle may be determined as follows: In the first place, there is orthophoria for distance and exophoria for near; exophoria far, greater exophoria near; or esophoria far and less esophoria near. Another method of determining this is that these patients will overcome a minus lens stronger than 3 diopters—they will overcome 4, 5 or 6 diopters and sometimes 7. Whenever there is delayed presbyopia, beyond the age of 45, there has been an abnormally large ciliary muscle, requiring a corresponding small nerve impulse. A weak muscle means a strong brain impulse and early presbyopia. This condition can be determined as follows: In the first place there is orthophoria for distance and esophoria for near: exophoria far, less exophoria near; or esophoria far, greater esophoria near. A weak ciliary muscle demands a strong impulse from the tenth conjugate center in the brain. It is generally understood that the center for the ciliary muscle is intimately associated with the third conjugate center for convergence. Every excitation of the tenth center means overexcitation of the third center controlling the interni, and means esophoria for near. These patients can not overcome a minus lens of 3 diopters: they will overcome a 2.50 maybe, or a 2, or a 1, and Dr. Savage has had patients who could not overcome a minus lens of .50 diopter. Dr. Savage related the following case: A confrère sent him a patient for consultation. The lady was 28 years of age and had other troubles besides a refractive error. She had had albuminuric retinitis and now has optic atrophy. She was suffering and no one expects suffering from atrophy of the optic nerve. The physician wanted Dr Savage to help him work out the case, and in testing the case Dr. Savage found that she had orthophoria for distance and 6 degrees of esophoria for near. A plus 1.50 D. sphere gave her orthophoria in the near. That woman had a weak ciliary muscle. It required a strong impulse from the tenth conjugate center in the brain. The impulse liberated from that center caused a corresponding excessive impulse from the third center controlling the interni, and hence the esophoria. With a plus 1.50 D. sphere before her eyes her esophoria was corrected. Now the absence of necessity for an excessive impulse from the tenth center put into a normal state of action the center in the brain acting on the interni. A plus 1.50 D. presbyopic correction for that woman, only 28 years old, will be most helpful. Dr. Savage said that the corrected hypermetrope will not have, as a rule, early presbyopia, for he has an abnormally strong ciliary muscle. Correct the hypermetropia, being always guided by the muscle condition as to ordering full or partial correction, and, if in early life the hypermetropia is corrected, the patient will go beyond 45 without the need of presbyopic correction. It means delayed presbyopia because hypermetropes have abnormally large ciliary muscles.

DR. HERMAN KNAPP, New York City, said that he wears bifocals and his eyes do not trouble him at all. He is hypermetropic and presbyopic, of course, and his sight with glasses is just as good as when young. He looks at a distance and reads without even bending his head, and operates with great comfort, even when doing fine work like a capsulotomy. He recommends these glasses as an immense comfort. The line where the segments meet gives a prismatic effect, however, no matter what any one may say to the contrary. This shows particularly in walking down stairs, when a person must be cautious in order not to misstep. It is his habit to examine every patient who has any nervous trouble with the ophthalmoscope, with glasses and also with the phorometer. In all these anomalies of refraction a cure is obtained. Dr. Knapp thinks that the trouble is not in the muscle and he is astonished that Dr. Savage speaks of the weak ciliary muscle. It is a mere hypothesis which has been used to explain the different anomalies of refraction; for instance, a myopic squint. When a patient comes to him with asthenopic symptoms, after using the ophthalmoscope he tries the glasses if everything is all right with the ophthalmoscope, and, in the great majority of cases, he finds hypermetropia of .50 or 1 diopter; if he goes further and examines them with the phorometer he finds 2.50 or 3 degrees of esophoria; when he puts the convex glasses before these eyes the esophoria disappears. The person who is hyperopic 2 or 3 diopters must make a very strong effort at convergence. He must send into the ciliary muscle an impulse to do away with the 2 or 3 diopters of hypermetropia and in that way the latent hypermetropia can be detected.

DR. MARK D. STEVENSON, Akron, Ohio, said that he uses homatropin in from 1 to 2 per cent. solution while the patient waits in a darkened room. The ciliary muscle yields more readily to the cycloplegic action of the drug in a dark room since the patient is unable to read or see objects. In a light room the patient tries to use his eyes and the ciliary muscle is constantly straining against the effect of the drug; this, with the dazzling caused by the enlarged pupil, gives rise to discomfort, often congestion of the tunics of the eyeball, and headache. Dr. Stevenson uses atropia in the young, if the patient can spare the time, and homatropin in nearly all other cases. The degree of strain found in some old people's eyes is sometimes surprising. He uses cycloplegics in all ages unless he finds tension, and in people over 35 or 40 he puts one or several drops of eserin in the eyes as soon as he has completed the examination. Young myopes are sometimes unable to wear their full distant correction for near work. In some of these cases, after proper trial, it is well to give bifocals or two pairs of lenses. Occasionally young people have more close work to do than the ciliary muscle can accomplish; in some such cases bifocals or two pairs of lenses are useful. The relation between accommodation and convergence is too often neglected. It is well known that people past the age of puberty gradually lose their accommodative power until they require a presbyopic correction. It has been Dr. Stevenson's observation that these patients usually at the same time lose some of their convergence power. The patient's accommodation is generally relieved by a lens which draws the near point closer. This accomplishes two things: It necessitates greater convergence and at the same time partially or wholly removes accommodation, one of the chief stimulants to convergence. Many presbyopes have weak convergence and the additional burden added by advancing the near point gives rise to discomfort. In cases where the convergence is weak, give a farther reading distance, prism exercises with strong prisms bases out, or sometimes even combine prisms with the lenses bases in, or the equivalent by decentering. Sometimes it is well in a high degree of insufficiency, especially if combined with weak adduction and strong abduction, to perform a tenotomy of the strong or an advancement of the weak muscle. In cases with great excess of convergence it is often well to give a short reading distance and rarely use prisms. Eyeglasses with bifocal lenses properly adjusted are often worn by patients who would lay spectacles or two pairs aside. The reading angle should be correct in such cases. The patient's vocation must be kept in mind in determining proper working or reading distance. In a paper presented to this Section in 1900 Dr. Stevenson called attention to the unequal accommodation in the two eyes. If possible, give distant lenses for a few weeks before prescribing for near. Too frequently the correction for near is determined after the accommodation is tired by a long examination for distant correction; in such cases the reading or working distance will be too close.

DR. WALTER L. PYLE, Philadelphia, stated that early in his career *his attention* was directed to the necessity of careful refraction, and to the value of cycloplegics. At the meeting of the American Ophthalmological Society in Washington, in 1903, Dr. Pyle reported the case of a patient aged 50, in which he used a single instillation of a 5-grain homatropin solution to get a better view of some peripheral lenticular opacities. On the morning of the third day she had violent acute glaucoma in both eyes. Dr. Pyle found her completely blind with both cornea steaming and with the eyeballs absolutely hard. He immediately performed posterior sclerotomy, which was followed by speedy relief. He also used hot applications and eserin. Within twenty-four hours the patient had normal visual acuity. The use of a drop of eserin solution before elderly or middle-aged patients leave the office avoids dangers of this kind.

Dr. Francis Valk, New York City, stated that in his work of fitting glasses for presbyopia, the more he leaves out the scientific ideas and gets down to natural methods the better seem to be his results. His objective point in fitting glasses for presbyopia is first to put the eye in a perfectly normal condition. The history of presbyopia in an emmetrope shows that they get along in life without any symptoms of asthenopia until they become 40 or 45, and then they require glasses. If they go to an optician and buy a pair of convex glasses, stronger as they need them, these glasses will carry them through life with no trouble. So, in a case of ametropia it must be put in the condition of the emmetropic eye by correcting the refraction, and then the addition of convex glasses will correct the presbyopia. In twenty-five years' work Dr. Valk has never found it necessary to use a cycloplegic in a case over 40 years of age. Some may find it necessary to dilate the pupil, but he has not met these cases. He corrects the refraction with the most careful objective examination, confirms this with glasses and then tests the range of accommodation. The text-books say bring the near-point up to eight or nine inches, but in many cases the position at which the patient works must be considered. His work may be at the desk and, if he has a very small region, this near-point must not be brought too close to the eyes. While Dr. Valk does not approve of the use of atropin in any case over 40, yet he would not hesitate to use it if he considered it necessary.

Dr. John S. Kirkendall, Ithaca, N. Y., agreed with Dr. Gould, but believes that the presbyopia spoken of by Dr. Stevenson in young myopes is apparent but not real. It is an acquired diseased condition, and if Dr. Stevenson continues to correct this apparent presbyopia in such cases he will add to the trouble by weakening the already atrophic ciliary muscles. Dr. Kirkendall's treatment of these cases is to thoroughly atropinize these patients, work out carefully their refraction and give them the full correction for both distant and near work, thereby developing the ciliary muscles, stopping the progress of the myopia and putting their eyes in the state of emmetropia; but at or about the age of 45 recognizes and corrects the presbyopia.

Dr. J. L. Thompson, Indianapolis, said that he is not afraid of mydriatics at all. When von Graefe and others spoke of the danger they used atropin. Dr. Thompson should as soon expect to rush on the *shield of Zeus* and get off without punishment as to use atropin. Many people over 60 have some accommodative power. He uses homatropin because it can be corrected so nicely with eserin. The patient can be kept in the office until the pupil contracts. There may be a simulated astigmatism in the *opposite* meridian to the usual one and on using a cycloplegic it vanishes. Dr. Thompson sometimes examines women patients at 38 *and then again* ten years later and they are still not 40. Find out their reading point and judge for oneself about their age. If patients refuse the bifocals they may have two pairs of glasses. Dr. Thompson thinks that Dr. Gould [illegible] the matter a little. Sometimes on a bright day Dr. Thompson has *migraine* when passing a fence or on looking at [illegible] bright carpet. He has had it suddenly develop when getting ready to operate, caused by reflection from the white caps of the sisters.

Dr. George M. Gould stated that he uses homatropin and cocain—two-thirds homatropin and one-third cocain; and does not hesitate to use it up to the age of 60, or any time, because in suspicious cases he *immediately* brings back the pupil and the accommodation to normal with eserin. This he does with young and old if they wish to use the eyes the same day. He uses the eserin in solution of 2 gr. to the ounce, and the patients read as before in fifteen or twenty minutes after several instillations. In presbyopic cases one avoids in this way all possibility of glaucoma. The stronger eserin may cause a little spasmodic twitching for a few minutes, but otherwise no harm, so far as Dr. Gould has observed. Dr. Gould does not see how Dr. Valk can correct presbyopia without the use of a cycloplegic and he will be grateful to anyone who can show him how to do it. He believes in correcting the astigmatism and in the slightly misplaced axes he can not do this without a cycloplegic. He finds a large number of cases with axes 10, 15 and 20 degrees off from the vertical or horizontal, and in young people that, in what he calls "the dominant eye," will produce tilted head, which often brings about compensatory spinal curvature.

THE USEFULNESS OF THE OPHTHALMOMETER.*

F. C. HEATH, M.D.
Secretary Indiana State Medical Society; Professor Diseases of the Eye, Central College of Physicians and Surgeons.
INDIANAPOLIS.

The ophthalmometer has gone through various stages of appreciation, depreciation and overpraise, back and forth over the same ground again and again; and still we have its enthusiastic advocates, claiming that it does away with the necessity of using mydriatics, while others consider it as merely an expensive scientific toy, utterly unreliable and of no practical value. Is it not worth while, then, to give the subject a few minutes of dispassionate consideration? Let us first take up the question: Is the ophthalmometer of any practical use in refraction work?

Those who argue against its usefulness base their argument on the ground that it only shows corneal astigmatism. The argument must turn largely, then, on the frequency and amount of lenticular astigmatism. Many authorities state that most of the astigmatism is corneal, and Suter and others explain the subtracting of half a diopter from the finding with the instrument in cases with the rule and adding the same amount in those against the rule by the fact that the lenticular astigmatism averages half a diopter against the rule. There is abundant testimony that this allowance should be made, and this certainly accords with my experience. A case will illustrate:

Case 1.—Miss G., a sufferer from headache back of the eyes, had worn +0.25 sph. right eye, +0.50 sph. left eye, for two years without relief and they blurred her distant vision, which was improved from 15/15— to 15/10 with +0.50 cyl. ax. 90° right, +0.25 cyl. ax. 90° left. The ophthalmometer showed 1 D. right, 0.75 left, axis 90° or 180°, *with the rule*. Assuming it to be probably convex from information already obtained and subtracting 0.50 D., the usual allowance, we get the same glasses she saw best with. These were prescribed and gave satisfaction.

The ophthalmometer here only increases our confidence. This case is a type of such a common experience as to seem trite. Everyone doing refraction work recognizes the difficulty in regard to cases with oblique axes, and the following illustrations are of this class:

Case 2.—A schoolboy, R. T., was referred to me because his teacher noticed that he saw poorly. Vision was found to be about 15/50 each eye and no glass seemed to improve it. The ophthalmometer showing 3 D. axis 15° or 105° right, 3 D. axis 165° or 75° left, we then tried +2.50 axis 105° right, +2.50 axis 75° left, which brought vision up to nearly 15/20. The astigmatism, axis and amount were revealed by the instrument.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

Case 3.—Miss C., aged 18, consulted me Sept. 15, 1902. She had been operated on for internal squint when a little child. For some time the left eye had been turning up and a little out, worse when the eye was tired. R. V. 15/15, L. V. 15/40; not improved by any glass. In fact, she thought this eye nearly useless. We talked of operating on the muscle, as she was fond of going into society and was much embarrassed by the disfigurement. Here the ophthalmometer came to our rescue, showing 3 D. axis 30° or 120° left eye and +2.50 cyl. axis 120° with +1 sph. brought vision in this eye up to 15/15 practically. A small amount of astigmatism was found in the other eye. She has worn the glasses then prescribed with greatest satisfaction ever since, the eyes being perfectly straight under the glasses.

Who would say after such an experience that the ophthalmometer was of no use? In the cases so far cited no mydriatic was used. Shall we say, then, that this instrument makes it unnecessary to use mydriatics? While there are many cases like the above where it seems safe to prescribe without paralyzing the accommodation, and while the ophthalmometer, by increasing our confidence in the result already obtained, or giving first clew to axis and amount of astigmatism, confirmed later by other tests, adds very greatly to the class that can be fitted safely without a mydriatic, yet we feel still greater confidence after an examination under cycloplegia in any case, and in many cases it is indispensable. For example:

Case 4.—C. T., wearing +1.50 sph. without relief to eyeache and with poor vision, seemed to accept +0.75 sph. each eye, but the ophthalmometer showed 0, which means either +0.50 cyl. axis 180°, or —0.50 axis 90°. Under homatropin his full correction was +1 D. sph. = +0.50 axis 180° both, thus confirming the instrument as to the astigmatism and correcting the mistake that would have been made by prescribing from the test by the lenses alone and showing what neither of the other examinations did, that there was compound hyperopic astigmatism.

But there is another advantage in using a mydriatic; it makes the examination with the ophthalmometer easier and more reliable. For example:

Case 5.—Miss J. A. came to me Aug. 24, 1902, with symptoms of eyestrain. She seemed to see best with +0.50 cyl. axis 105° right, +0.50 axis 75° left, and the ophthalmometer indicated the same. These were prescribed and gave partial relief for a year, when she returned to see if they could be improved. This time homatropin was used and the same amount of astigmatism was shown both by the test lenses and ophthalmometer, but instead of the oblique axes both methods gave 90°.

This shows that the axis of the corneal astigmatism may be made to change probably by the lids pressing on the balls in straining to see, and this is avoided or lessened when the eye is put at rest by the mydriatic. A few other cases have shown different axes under the mydriatic from those of first test.

In view of what has been said it might seem unnecessary to consider the question: Is the ophthalmometer an infallible guide? But it will be understood that we mean subject to the limitations already expressed. In other words, Can we rely on the ophthalmometer in all cases, both as regards axis and amount of astigmastism, even after use of mydriatics? We can answer this best from our case book:

Case 6.—Mrs. M., a sufferer from headache, had a small astigmatism recognized by the ophthalmometer in both eyes, axis 90° or 180°, while test lenses under homatropin gave left axis 135°, which was ordered.

Case 7.—A little girl with frontal headache saw best with +0.50 axis 135° right, +0.50 axis 45° left, and homatropin confirming this, they were prescribed in spite of the fact that the ophthalmometer did not give oblique axes, and they relieved the symptoms.

Case 8.—Miss M. on first test took +0.50 axis 90° right, +0.50 axis 180° left, which was apparently confirmed by the ophthalmometer, but homatropin showed simple hyperopia in left eye.

A few other similar cases have been observed, and two in which the instrument gave 1.D. more astigmatism than homatropin.

It is evident, then, that we have not an infallible guide in the ophthalmometer. Some one may ask, Do not the cases just cited prove as much against the instrument as the other cases did in its favor? They would, if numerous; but these cases are very exceptional, not types of many found in every-day experience like those cited in the argument in favor of the usefulness of the instrument. In fact, I have given nearly all the exceptional cases observed from June 1, 1901, to Jan. 1, 1904, under this head, and most of these can probably be explained as examples of unusual amount of lenticular astigmatism, or those where accurate ophthalmometric readings were rendered impossible by undue action of the lids, restlessness of the patient or other similar difficulties.

If not infallible, what are the limitations? This has already been answered, in part at least. It does not show lenticular astigmatism, which is an important factor in some cases, and there is some liability to mistakes from hasty work of the observer, restlessness of patients, contraction of lids, failure to look in direction desired, etc. Of course, it does not show hyperopia or myopia; in fact, it does not even show whether the astigmatism is hyperopic or myopic, except that a long radius suggests the former, a short one the latter. Yet it is very useful in spite of these limitations, and this leads to a comparison between this and other methods of measuring refraction.

This comparison will be limited to use of test lenses, with and without mydriatics, retinoscopy, the ophthalmoscope and the ophthalmometer. The objection to relying on the test lenses without a mydriatic is that the patient often accepts the wrong glass on account of undue or irregular contraction of the ciliary muscle. We do not need to cite cases to show that this method alone is very uncertain. Cases already cited bring out the advantage of supplementing this by the ophthalmometer to confirm or correct the result of the tests, and in many instances we find vision better with the glass suggested by the instrument.

However doubtful we may be about results of tests with lenses alone, there is probably no other method so sure and satisfactory when supplemented by the use of homatropin, scopolamin, atropin or other substances to control the accommodation. In other words, what the patient sees best with, when the eyes are under the influence of a cycloplegic, is the measure of his refractive error, to be relied on, if at variance with the findings by other methods.

Yet even here we should be careful that we have what the patient actually sees best with, and not what he seems to see best with. I have seen examinations under a mydriatic where astigmatism was found with axis perpendicular, apparently, in which the ophthalmometer gave

15° off, and later trial of this axis actually showed improvement in vision. It may be said that this ought to be discovered by trying the cylinders at various angles in the ordinary tests, but we know that patients often fail to detect small differences, and it frequently takes several trials and much care to bring them out, so that an instrument which quickly suggests the axis is of immense value.

The ophthalmoscope is of greatest assistance in high degrees of refractive error, enabling us to measure them approximately in a very short time, but it is not of much account in small defects, which form quite a large proportion of our work.

Retinoscopy would probably be voted by the majority of oculists the best (objective) method of measuring refraction. More is to be learned from it than from any other one (objective) method, as it shows hyperopia or myopia as well as astigmatism, and its measure of the latter is not limited to corneal astigmatism, but includes the lenticular as well. Now, if this all be true, practically as well as theoretically, and if we could all measure by this method any kind of refractive error down to 0.25 D., as some claim to do, no other method would be necessary, and even the trial case might be dispensed with. But retinoscopy has its drawbacks, too; it requires a mydriatic in all cases, and even then one has to be careful to get the refraction of the center of the field, and not the periphery. The method is also a slow one and necessitates the awkward changes of lenses from the trial case, or use of some cumbersome apparatus like the Würdemann skiascope in the hands of the patient, which can not be used easily, especially with children. Moreover, there is ground for skepticism as to the skill claimed by some to measure even 0.25 D. of any kind of refractive error by this method in a few minutes; at least such skill is limited to a few. Nevertheless it has some advantages, and there is ground for much that is said in its favor. It is especially valuable in examining little children and illiterates.

While the ophthalmometer gives less information than retinoscopy, what it gives is obtained more easily, more quickly and is more positive. In other words, it is the quickest and surest way of measuring corneal astigmatism, and since we have a definite rule for the majority of cases in regard to the relation between corneal and total astigmatism and can determine the hyperopia or myopia by the ophthalmoscope and test-lenses, we have, in my judgment, in the ophthalmometer, combined with these other means, a method for general use not surpassed by any other for accuracy of results or speed in execution. An additional point is the fact that this instrument is so much more valuable in those cases where a mydriatic is refused, and adds so largely to the number that can be quite safely fitted without the annoyance and loss of time due to paralysis of the accommodation.

CONCLUSIONS.

1. The ophthalmometer is not merely an expensive toy, but a very useful instrument.
2. It shows the corneal astigmatism which, in most cases, is 0.50 D. more than the total astigmatism if with the rule, or the same amount less if against the rule.
3. It does not do away with the necessity of using mydriatics, although it adds largely to the number that can be fitted with comparative safety without them.
4. It is not infallible as regards axis or amount of astigmatism, but the cases in which it misleads are exceptional and probably the result, chiefly, of unusual difficulties and irregular or extraordinary lenticular astigmatism.
5. It is one of the quickest and surest methods of determining astigmatism, either axis or amount, frequently giving the first clew.
6. In connection with the ophthalmoscope and test-lenses (in many cases with use of a mydriatic), it is as good a routine method of measuring refraction as we possess.

This is submitted not dogmatically, but with the hope of starting a discussion which will give us the exact truth.

427 Newton Claypool Building.

DISCUSSION.

Dr. Wendel Reber, Philadelphia, said that he has used the ophthalmometer a great deal, but that he is not so enthusiastic as Dr. Heath. He uses it almost invariably in his office work, and, while he does not claim to be able to measure cases to within a quarter diopter with it, he can measure down to such a degree that he knows about what the corneal astigmatism is. Mydriatics, of course, are always refused by the patient at first. The ophthalmometer is most valuable, he thinks, as to its negative evidence; that is to say, in the lowest errors one does not get reliable evidence, but where there is one or more diopters one gets very good results. In cases of cataract, of course, it is important to know the amount of corneal astigmatism. While it is an important office adjunct, at the same time it is certainly not the faithful, accurate servant that retinoscopy is.

Dr. J. M. Ray, Louisville, Ky., declared that, while recognizing that the ophthalmometer does not reveal the absolute amount of astigmatism in all cases, yet in daily use he thinks it invaluable as an aid in finding the astigmatic error. It is usually accurate as to the axis. He has used it for fourteen years on several thousand cases and would feel lost without it.

Dr. C. F. Clark, Columbus, Ohio, stated that he has been a persistent user of the ophthalmometer, and feels as Dr. Reber does about it. He asked why, in post-cataract cases, we do not obtain a correct result with the ophthalmometer. If the corneal astigmatism is accurately shown by the instrument, he asked why, when the lens is removed, we can not get a correct reading. There may be three diopters with the ophthalmometer, when only two will be the correct estimate.

Dr. Edward Jackson, Denver, said in reference to Dr. Clark's question, that the scale of the ophthalmometer is made out for the complete eye; it does not fit the aphakic eye; it does not give the true curve. After cataract extraction, there is an area toward the corneal section that shows the greatest departure from the original curve. He uses the ophthalmometer in every refraction case, but he does not depend on it. It is like the averages in presbyopia. One must test by the other methods afterward and see if it is correct.

Dr. F. C. Heath, Indianapolis, agreed with Dr. Jackson that the ophthalmometer is not to be relied on alone. It is not infallible. He does not consider it an exaggeration to say that he finds in 75 per cent. of his cases of astigmatism that the ophthalmometer is correct.

The Abdominal Aorta in the Aged.—Bauer holds that the abdominal aorta is frequently the site of a chronic aortitis which less frequently affects the arch (*Arch. Gen. de Med.*). The symptomatic manifestations are irregular as a rule, but occasionally symptoms point more or less directly to the condition especially in emaciated individuals in whom palpation and auscultation can be employed. In fleshy individuals the difficulty is greater, but persistent digestive disorders, lassitude, early fatigue, various sensory symptoms such as local feelings of cold, numbness, vague pains in the limbs, sometimes painful cramps, trophic disorders, etc., may point to the condition. It is often, however, undiagnosed; in rare instances attention may be called to the condition by an aggravation of acute or subacute aortitis.

INTERNAL AND EXTERNAL HEMORRHOIDS.

WITH SPECIAL REFERENCE TO THEIR TREATMENT.*

LEWIS H. ADLER, JR., M.D.

Professor of Diseases of the Rectum, Philadelphia Polyclinic and College for Graduates in Medicine; Prosector to the Professor of Anatomy, Medical Department of the University of Pennsylvania; Consulting Surgeon, Charity Hospital.

PHILADELPHIA.

I have been requested to address you on the subject of hemorrhoids, viewed so far as possible from the standpoint of making my remarks of value and interest to the general practitioner. Time permits of only a brief synopsis of the subject.

Without making a thorough examination of a given case, no certain diagnosis can be made and no plan of treatment can be carried out with any degree of satisfaction. In most departments of medicine this fundamental principle is carefully observed, but possibly owing to a false sense of modesty on the part of patients afflicted with rectal trouble, some physicians are led to treat such persons without an exploration, either visual or digital, of the affected region. Consequently, it is not an infrequent occurrence for me to see a patient with an external hemorrhoid, greatly aggravated by the vain efforts made to push it within the anus. This illustration will suffice, no doubt, to emphasize the necessity of examining every case of presumed rectal trouble. Such an examination should include not only an ocular inspection of the parts outside the anal canal, but likewise a digital investigation of the rectum. It is only in cases of irritable ulcer of the anus (fissure) that an examination with the finger should be omitted. A rectal examination is not a very pleasant one, either to the practitioner or to the patient. yet without making it the physician's reputation, as well as the patient's health, may suffer.

Assuming, therefore, that attention has been paid to the proper methods to insure the making of a correct diagnosis. we are prepared to consider the variety of hemorrhoids, preliminary to a consideration of the treatment of the individual forms.

EXTERNAL HEMORRHOIDS.

External hemorrhoids are divided into the venous, the cutaneous and the compound.

Venous.—The venous variety occurs in three forms: 1. As a marked varicose condition of the plexus of the external hemorrhoidal veins. 2. As a thrombosis of this plexus. 3. As a clot of extravasated blood, due to a rupture of a varicose vessel. The existence of this last variety is denied by some authorities, but I have seen and operated on a number of such cases sufficient to warrant the classification given.

Cutaneous.—The cutaneous pile consists essentially of a hypertrophy of the skin surrounding the anus. It frequently is the result of a former venous hemorrhoid, a fold of skin being left after the clot has been removed. either by absorption or operation. When uninflamed, it occasions no great inconvenience, but when aggravated by improper diet, irregular habits, uncleanliness. etc., it invariably causes the patient an amount of suffering quite disproportionate to the pathologic appearance.

Compound.—The compound or so-called externo-internal pile is one in which the tumor is not only largely external, but is also intimately associated with an internal hemorrhoid, and is, therefore, in part, covered with mucous membrane.

INTERNAL HEMORRHOIDS.

Internal hemorrhoids are divided into the varicose, the capillary and the compound or intero-external.

Varicose.—The varicose or venous internal hemorrhoid is the form of tumor most frequently met with in the bowel, and consists of a varicosity of the internal hemorrhoidal veins, with a hypertrophy of the surrounding tissue in which these vessels are embedded.

Capillary.—The capillary or nevoid hemorrhoid consists of a small, raspberry-like arrangement of the arterial capillaries within, or just beneath the surface of the mucous membrane of the rectum. They are the source of frequent hemorrhages due, no doubt, to a covering of a very thin layer-of epithelium, which is readily ruptured. They do not protrude and can not be located by digital examination.

TREATMENT OF EXTERNAL HEMORRHOIDS.

The local treatment of these tumors may be considered under the two heads, the operative and the palliative. It is only when these tumors are inflamed that patients suffer marked inconvenience, and find it necessary to consult a physician, and it is at such a time that I believe the best method of treatment is that of removal. If, however, the patient refuses to submit to our judgment in this matter, recourse must be had to local applications for the relief of the suffering incident to the acute inflammatory stage. What we have to say regarding the treatment of piles which are external applies with equal force to all the varieties included under the classification of this form of hemorrhoids.

Operative Treatment.—It is only by this plan that we may effect a radical cure. It may be accomplished by one of three methods, named in the order of our preference: (*a*) excision, (*b*) simple incision, and (*c*) excision and primary suture of the cutaneous edges of the resulting wound.

(*a*) EXCISION is the mode of treatment now employed by most proctologists for the cure of all the various forms of external hemorrhoids when the patient is seen in the acute stage of the trouble. The operation consists in washing the parts well with the tincture of green soap, alcohol and creolin, so as to render the field of operation as aseptic as possible. The hair is not shaven, as experience has shown that it is unnecessary. Formerly when the hair was removed, its subsequent growth was most annoying to the patient, feeling somewhat as though the vicinity of the anus had been converted into a pin cushion (by no means an empty one). The tumor to be removed is now anesthetized by means of a hypodermic injection of a 2 per cent. solution of the hydrochlorate of cocain. of which from 10 to 20 minims usually suffice. In connection with the use of local anesthetics, attention is called here to a matter. with which I have had no personal experience, but which justifies note. to-wit: The work done by Dr. Samuel G. Gant of New York City in the use of sterile water anesthesia in the office treatment of rectal diseases.[1]

Before removing the needle of the syringe, time is given the solution to permeate the tissues. The pile is next grasped by some suitable instrument, such as a hemostat (sometimes by two. if the hemorrhoid be a large one). and the tumor is rapidly removed in its entirety by means of a pair of scissors curved on the flat. It is rare that any vessels of size are met with and the ease with which, in this region, a bleeding vessel can retract and contract, obviates any necessity for the use of the ligature. All clots are removed. The resulting wound is now lightly packed with cotton, which is changed several times until most of the bleeding is stopped. The flow of blood is encouraged for a short time so as to get rid of any excess of cocain remaining in the vicinity.

---

* Read before the meetings of the Northwestern Medical Society and of the Medical Society of Germantown. Philadelphia. 1904.

[1] New York Medical Journal. Jan. 23. 1904.

Finally, when active bleeding has ceased the wound is packed with gauze, a 10-grain iodoform suppository is inserted into the rectum, and over the seat of operation is placed a firm pad of gauze and cotton and then a "T" bandage completes the dressing.

(*b*) Simple incision requires a similar technic to that described for excision, with the exception of the operative part. This latter is accomplished by catching the parts on either side of the tumor between the thumb and forefinger of the left hand and transfixing its base in the direction of the radiating folds of the anus with a sharp-curved bistoury and cutting outward. Gentle pressure will cause the extrusion of most of the clots; any of them remaining may be picked out with a pair of forceps. The subsequent treatment consists in packing the wound with gauze and then using a similar dressing to that advised in the operation of excision. The main disadvantage of this operation consists in the fact that the skin distension occasioned by the inflamed pile is left, and may subsequently become inflamed or may refill with blood.

(*c*) Excision Combined with Primary Suture of the Resulting Wound.—The essential difference between this method and that of simple excision consists in the close apposition of the wound by carefully buried silkworm gut, or some similar, suitable material. The advantage of the operation lies in the hope of obtaining primary union. I have practically discarded this method, as the suture tracks are liable to become infected, and I think the mechanical presence of the sutures, together with the constriction they produce, combine to add materially to the annoyance to the patient than when the parts are left to heal by granulation.

The Non-Operative or Palliative Treatment.—This consists primarily in keeping the parts thoroughly cleaned by bathing with water as hot as can be borne and in applying some soothing and astringent lotion during the acute inflammatory stage. Some of the preparations which I have employed with satisfaction are: Ichthyol, 50 per cent., combined with equal parts of lanolin and ung. aquæ rosæ; or a mixture, containing one ounce of the fluid extract of hamamelis; a half-ounce of the fluid extract of hydrastis; a like amount of the compound tincture of benzoin and two drams of the tincture of belladonna. This solution is to be well shaken before using, and is kept in the bottle and placed either in hot water and applied frequently by means of hot compresses to the affected part, or if cold is more agreeable to the patient, then the medicine is surrounded with ice and compresses wrung out of ice water are kept saturated with the mixture and are applied in the same manner as when they are used hot. Another useful mixture is the strong subacetate of lead solution, combined with an equal quantity of the tincture of opium, of which a teaspoonful is added to a wine glassful of cold milk and applied with frequency to the anus. In addition to these measures, the bowels should be freely moved, and a light, easily digested diet, with rest in bed, prescribed. These remedies will, as a rule, cause the inflammatory symptoms to subside within a few days, but usually a thickened tag of skin will remain, which is liable at any time, on the slightest provocation, to become inflamed.

TREATMENT OF INTERNAL HEMORRHOIDS.

With the exception of the nevoid or capillary pile the treatment of these tumors may be discussed under the following classification: (*a*) Preventive, (*b*) palliative and (*c*) operative.

Prior to taking up this part of our subject, it may be well to say a few words regarding the treatment of the capillary hemorrhoid. The safest method of effectually dealing with this condition consists in the use of the electrocautery applied by means of a small electrode. Anesthesia is not essential. Care must be exercised not to cauterize too deeply. A very old and deservedly popular treatment of this form of pile is the use of fuming nitric acid. Care must be exercised not to excite too intense an inflammatory reaction. The pile is caused to protrude into a speculum, is thoroughly dried with cotton on the end of an applicator, and then the acid is applied all over its surface by means of a rod of glass or a stick of wood. Before removing the speculum, which is left *in situ* for three or four minutes, a dossile of cotton is placed over the treated area so as to absorb any excess of the acid.

Caution in the use of the acid is necessary in order to avoid its getting on the cutaneous surface or on the margin of the anus. A good preventive measure against this accident is the smearing of the region named with glycerin or vaselin. One treatment of the acid usually suffices to stop the bleeding, but two or three applications may be required to completely destroy the tumor. These applications may be repeated at intervals of three to seven days.

Preventive Measures.—These consist, to a large extent, in the avoidance of the sedentary habits, the use of improper toilet paper, such as newspaper, printers' ink being a decided irritant, excessive venery, improper diet, the excessive use of alcohol or tobacco, and last, but not least, the constantly increasing employment by the populace of drastic purgative medicines. To cure the constipation, which is the result of the forenamed conditions, and which, to my mind, is the most frequent cause of piles, it is essential that regularity be observed in the time of going to the closet. This is the first step to be taken in the correction of this condition. Patients should be directed to go at the same hour daily, whether the desire exists or not. Before or after the morning meal will usually prove the best time. Physical exercise is another very important factor in correcting costiveness. To be of benefit it must be employed regularly, spasmodic efforts being harmful rather than effecting good results. Certain articles of food often aid in the removal of this affection, such as the fruits, of which apples, oranges and prunes are the best.

Medically, the treatment of constipation covers a wide range of remedies. No one plan can be outlined that will benefit all, or even the majority of persons so afflicted. It is impossible to consider this phase of the subject further, as it would necessitate prolonging this article to an unreasonable length.

Palliative Means.—This plan of treatment to accomplish the desired results must embrace a three-fold purpose: 1, The reduction of any inflammation; 2. the arrest of hemorrhage; and 3, the prevention of prolapse of the tumors. It also includes careful attention to all the details enumerated under the head of preventive measures. In the early stages of the hemorrhoidal formations, cold water will often prevent further annoyance, when applied directly to the anus on a sponge, and also by injection into the bowel of a small quantity. The method of sponging the parts must be carried out systematically and regularly. To be successful, a large natural color sponge (one not bleached) must be secured about the size of one's fist.[2] This is soaked in cold water, and pressed against the anal region until all the fluid is extracted, and this procedure is repeated anywhere from fifteen to twenty-five times. The application of the water should be made both night and morning, and especially after a stool, when a protrusion is most liable to occur. The enemata need only be employed just prior to the time when the bowels are ordinarily evacuated. Sometimes considerable benefit is derived from an injection of a small quantity of cold or even ice water into the rectum, immediately after the movement of the bowels, and retaining it as long as possible.

For the relief of inflamed hemorrhoids, Dr. D. G. Gant[3] advises the use of the following simple ointment, which is very effective:

℞. Morphinæ sulphatis................gr. viii |5
Hydrargyri chloridi mitis..........gr. xii |7
Vaselini ....℥i 30|

M. Sig.: Apply freely in the rectum to the tumors and about the anus. Always bathe the parts with hot water before applying the salve.

The tendency of piles to bleed may be stopped by the use of suprarenal extract, either in the form of an ointment or a suppository, ten grains to a dram when used in a salve, and in doses of five grains when a suppository is employed. The prolapsing of the tumors is best arrested by the use of cold water, as previously advised. A useful suppository, in this connection, is one advised by Dr. James P. Tuttle:[4]

℞. Ichthyol
Tannic acid, āā........................gr. v |3
Ext. belladonnæ
Ext. stramonii, āā....................gr. 1/3 |02
Ext. hamamelis ....gr. x |6

M. Ft. suppository No. i.

Operative Measures.—Of these methods I have only time to give a brief summary of the opinions I have formed regarding five of the methods, to-wit: 1, Divulsion; 2, injection; 3, ligature; 4, clamp and cautery; and 5, Whitehead's operation.

1. DIVULSION.—This operation, done under nitrous oxid gas and oxygen, often exerts a most beneficial temporary effect, especially when a patient is suffering from strangulated piles and refuses any more radical treatment. Relief for a time is obtained thereby also from constipation, but the effects, I regret to state, are not permanent unless the patient adheres to the rules laid down for the prevention of costiveness. The operation of divulsion is an essential preliminary step to the treatment of a patient by the Martin, of Philadelphia, injection method, the details of which are soon to be published by the son.

Under gas, muscular relaxation does not obtain as in the use of ether. Hence dilatation under gas can be more rapidly induced, as we have the sphincteric rigidity as a guide in knowing exactly how much force may be employed in the individual case. The operation consists in overstretching the muscles with either the fingers or thumbs, or both, until all spasm is overcome. Care must be exercised not to tear the parts. My experience with this method, employed especially for the cure of fissure (irritable ulcer of the anus), enables one to say that the time occupied in the performance is less than half that under ether.

This operation is, therefore, indicated for the temporary relief afforded in a case of strangulated piles, when other operative measures are refused by the patient, and as a preliminary step to the treatment of piles by the injection method.

2. INJECTION.—Radical cures are effected by this means. Various formulæ are advocated. The principal difference in the methods being (1) in the use of strong solutions in large quantities, which cause a necrosis of *the entire hemorrhoidal* tumor; and (2) the employment of weaker solutions and smaller portions which, as my friend, Dr. James P. Tuttle,[3] expresses it, "produces an inflammatory induration and choking of the circulation, which is followed by shrinking and atrophy of the piles without ulceration or sloughing." In a paper, "The Treatment of Hemorrhoids by the Injection Method," reprinted from the *Therapeutic Gazette*, August, 1897, I detailed the method which I at that time employed, and expressed the conviction that the plan of treatment was efficient and satisfactory. (My later experience in this line I gave in a paper at the annual meeting of the Pennsylvania State Medical Society, Sept. 26-29, 1904.)

3. LIGATURE.—Some of my distinguished colleagues regard the use of the ligature as the ideal operation for the radical treatment of hemorrhoids. Dr. Joseph M. Mathews[5] states, quoting Erichsen, that "all external piles should be cut off, and all internal piles tied, and that he (Mathews) does not think that the advice then given can be improved on, even to this day. I am certain that in the hands of my skilled friend the operation proves all that he claims for it.

4. CLAMP AND CAUTERY.—This is the procedure which holds my preference over all other methods for the radical cure of hemorrhoids. A brief summary of the reasons why I view the operation in this light consists (1) in the fact that patients suffer the least pain; (2) that their recovery is quickest; and finally (3) that the constitutional effects, such as inability to urinate without catheterization, is least disturbed. The time required for a cure to be effected by this operation is at the outside two weeks. A patient after the operation has the bowels moved on the third day; is allowed to get out of bed on the fifth to the seventh day, and then is permitted to go home in from seven to ten days.

5. WHITEHEAD'S OPERATION.—I have never performed this operation, being unable to bring myself to a belief that the cases of hemorrhoids which have come under my observation justified the risks attending its performance. Not only are all the delicate structures in the anal region removed by this procedure, but there is also the grave possibility of a stricture following, should healing not occur by primary union. The plan of operation, in itself, reflects considerable credit on the ingenuity of its distinguished originator. I question, however, it ever reaching a popular professional employment.

[5] A Treatise on Diseases of the Rectum, Anus and Sigmoid Flexure, New York, 1892, p. 158.

Dr. Charles M. Kelsey[6] epitomizes this entire subject in the following advice given to students attending his clinic:

> If you wish to radically cure your patients with the least possible pain, loss of time, confinement to the house, and risk of accident, use the clamp and cautery.
>
> If you wish to accomplish the same results with no more risk, but with more pain, more local and general disturbances, use the ligature.
>
> If you wish to take an hour to do what can as well be done in a few minutes, and gain nothing more by it in the results, use Whitehead's operation.

1610 Arch Street.

PRE-OPERATIVE AND POST-OPERATIVE TREATMENT OF SURGICAL CASES.*

L. SEXTON, M.D.
NEW ORLEANS.

The question has often occurred to me that some surgeons at least view all therapeutic measures as more or less empirical or useless, and lay too much stress on what can be accomplished by operative procedure alone.

Specialists in any given line are prone to look on any given subject from their point of view; in fact, we are of the opinion that many surgical cases before operation are not treated as they should be, so as to prepare them for the great ordeal and shock incident to a major operation, and as a result of this lack of treatment or proper preparation before operation, they are likely to have to be overtreated after or during the operation.

As a matter of course, in emergency surgery, we often have no time for general treatment, but many other surgical cases are materially benefited by proper attention to their general health, the careful flushing out of the bowels, kidneys and liver; the regulation of the heart as to its beat and tone; respiration as to its depth and regularity, and the proper building up of the nervous system and the blood count by suitable medication.

We have seen much good result from dieting, tonic capsules of iron, quinia, strychnia and cascara or liquid preparation of iron and manganese preceding some operation, especially in anemic malarial subjects, which, without the previous building up, would hardly have been able to undergo the shock of any serious operative interference. In other cases, where the long drain of chronic diseased conditions have undermined the nervous and circulatory systems, much good may be accomplished by giving digitalis, strychnia and iron, till the heart is toned down by digitalis, and the nervous system braced up by the action of the strychnia and the blood count built up by the iron. As a matter of course, no imperative operation should be made to wait for the result of such medication, but the idea that we mean to convey is that when any such case may have to wait from any cause, the period of such waiting should be utilized in the general up-building of the patient's vitality.

Many times surgeons are called on to operate on patients who have led rather fast lives; who have not only burned the candle at both ends, but have overtaxed the stomach, overworked the liver, and kept the kidneys choked with excrementitious material which should have been flushed out. All such cases are very much benefited by thorough purgation with calomel and soda, or any other simple cathartic, if mercury is contraindicated. The thorough emptying of the bowels and stimulation of the secretions does away with half of the vomiting, which we have seen in cases which have not been properly purged before the operation.

Regulation of diet for several days previous to an operation so that no indigestible material is left in the alimentary tract, is another important detail to look after. The greater the quantity of water imbibed and the better the kidneys and bowels are flushed out, the better the chance for the patient to stand the operation.

In emergency operations one-fourth grain of morphia, enemas of hot milk, coffee and whiskey all tend to ward off shock. In any serious operation, Professor Smith recommends the previous administration of whiskey almost to the point of intoxication.

This plan is more suitable for subjects accustomed to drink than to follow as a general rule. The application of bandages formerly recommended to store up blood in the extremities is not practiced to any extent at present, but the saving of all the blood possible by the Esmarch bandages and the elevation of the limbs to be amputated, is doubly important in all very young or old subjects.

Mikulicz found that blood regeneration in an operation in which 1 per cent. of blood was lost, was made up in from two to five days; that 3 per cent. was made up in from five to fourteen days, and 4 per cent. was regenerated within thirty days. Usually we expect the blood regeneration to be complete within fourteen days. Mikulicz never operates on a patient whose hemoglobin is under 30 per cent. In all anemic and accident cases, where a great amount of blood has been lost, this 30 per cent. hemoglobin test is a good rule to follow, waiting, if possible, to build up the hemoglobin to the required 30 per cent. standard before operation.

We often see mucous patches and syphilitic ulceration of mouth, tongue and throat that in some degree resemble epitheliomatous growths so closely that it is hard to differentiate between the two. Recently such a case came under my observation, under the treatment of a throat specialist, who informed the patient that he had cancer of the tongue and tonsils, and must undergo a complete removal of those organs with all the deformity and consequent inconvenience incident thereto. The pathologist had examined the tumor and reported it an epitheliomatous growth. It certainly looked suspicious, and had a cancerous history, but behind all of this was also a vague syphilitic history. The patient refused to be operated on without seeing another specialist, who, on consultation, decided to try the test of free administration of iodid of potash and mercury, so the patient was given 20, 30 and 40-grain doses of iodid of potassa three times daily, well diluted, after meals, combined with protoiodid mercury pills. The effect of the treatment began to show after the first week, in diminishing the size of the ulcer and causing it to become paler and less hemorrhagic. Two weeks noted more marked improvement, and within a month the tumor had disappeared and the ulcer healed. In all cases of ulceration about the throat and tongue in syphilitic suspects, give the test treatment with iodid of potash and mercury, before any operative procedure is suggested. The time required for the test is only one month. The power of iodid of potassa and mercury in effecting such cures is almost miraculous. This recommendation, if followed, will clear up many suspicious diagnoses.

So much for pre-operative treatment. Let us now turn our attention to the patient who, from loss of blood, shock and anesthesia, or any other cause is *in extremis,* as the antiseptic details of modern surgery tend to prolong operations and to the production of shock.

---

[6] The Treatment of Hemorrhoids, New York Med. Jour., June 16, 1894.

We can hardly speak of post-operative treatment without going into the definition and details of shock. The demand for treatment is usually brought about by the loss of blood, shock or fat embolism. The essential condition of each is anemia of the brain, fast, weak-acting heart, inhibition of nerve force, with reflex paralysis, exhaustion of the active force of the medulla oblongata and spinal cord, accompanied by subnormal temperature. The weakness of the heart's action, combined with the paralysis of the vascular tone disturbing the circulatory balance, the abdominal veins become overfilled by gravitation, and the right side of the heart is greatly distended. These conditions necessarily lessen the amount of blood in the arteries. If this arterial pressure is very much lessened, anemia both of the lungs and brains soon follows. A slight degreee of shock may follow almost any traumatism or great loss of blood, but it is more severe in contusions and gunshot wounds of the viscera, crushing injuries of the extremities and testicles, and to burns and scalds extending to half or more of the body surface. We can differentiate hemorrhage from shock to some extent by the blood count, which should not fall below 3,500,000 The nature of the injury will also assist in making the diagnosis. In shock, circulation is vitally depressed. It is supposed in the case of crushed limbs to be brought about by nervous exhaustion, caused by continuous and severe irritation of peripheral, sensory and sympathetic nerves.

Rogers, in experimenting on frogs that he had shocked by electricity, observed that the spinal cord and muscles were not sensitive to drugs or stimuli, as, for example, strychnin failed in its effect on the spinal cord. The tissues seemed to be unable to react, or the strychnin seemed to fail of passage from the blood to the tissues. These experiments in part explain some of the observations of Crile, namely, that powerful, stimulating remedies fail in their mission to relieve exaggerated shock, and when given in too large doses may result in an absolute toxic effect on the patient. The following observations of Crile, while some of them are contrary to our clinical experience, are worthy of note in this connection. Crile contends that nitroglycerin, strychnia, alcohol and all other stimulants of vasomotor centers tend, like traumatism, to the production of shock.

Where the operative field invades a part rich in blood vessels and hemorrhage is hard to control, the amount of blood lost is often great in quantity, even though we use all the precautions possible by immediately clamping or tying every vessel that spurts. It is after such operations and in collapsed conditions that intravenous infusion and hypodermoclysis accomplish such good results by raising blood pressure, stimulating the endocardium, thus exciting the heart to action, filling up the empty blood vessels and stimulating the anemic brain. The amount of saline infusion should be governed by the amount of blood lost and its effect on the pulse. It is better to stop at two pints, if the pulse is restored, taking the chances of having to repeat it again if required, rather than to bring about pulmonary edema, for Crile found when the infusion amounted to 320 c.c. kilo., the fluid accumulated in the splanchnic area and embarrassed respiration by mechanical fixation of the diaphragm and ribs. We have seen pulmonary edema increased and damage done by using intravenous infusion in a case of albuminuria with suppression of urine.

Crile had the most lasting effect when to his saline infusion he added 1/50,000 adrenalin. He resuscitated animals that had been dead for ten (?) minutes by these infusions, combined with rhythmic pressure on the pericardium and artificial respiration.

We may have delayed shocks after an operation is completed, hence the importance of keeping the patient quiet and comfortable, with the foot of the bed raised, if much blood has been lost. During collapse the best clinical results are obtained medicinally by the hypodermic administration of 1/30 grain of strychnia, combined with 1/60 grain digitalin. If we could foretell, in any given operation, that shock was liable to occur, it would be well to reinforce our patient by giving him either a stiff toddy, ¼ grain of morphia, 2 grains citrate caffein, or a hot cup of coffee an hour or two before operating.

When from any cause serious or profound shock is produced, only the necessary interference to check the hemorrhage and stop the pain should be attempted, and even that should be done without the aid of anesthesia; morphia, under such circumstances, acting better than ether or chloroform. The exception to this rule is when the shock seems to be aggravated by a crushed painful limb; it is better to amputate under the influence of morphin and ether, thus removing the cause of the shock. The blood should be forced into the more vital parts by raising the limbs, if not injured, rather than by bandaging the extremities. Dry heat and mustard with friction to be applied freely, flannel cloths wrung out of hot water and sprinkled with turpentine should be applied over the precordial region. In some of these cases the most powerful stimulation fails to act. When, from either shock or anesthetic, respiration or circulation stops from anemia of the medulla oblongata, the head-down, inverted position, combined with artificial respiration with rhythmic pressure on the heart, affords the best chance for relief. Artificial respiration, with chest compression, not only brings in new oxygen, but expels whatever chloroform or ether vapor remains with the residual air. It is then that artificial respiration, lowering the head, infusion and faradization come to our relief. With one pole of the battery over the phrenic nerve and the other over the diaphragm, we can tide over some cases that otherwise might prove fatal. We should not try to force hot, stimulating drinks down a patient who can not swallow, as fatal strangulation may result, but if deglutition is not impaired, 10-minim doses of the tincture of digitalis dropped on the back of the tongue slows down the fast, weak-acting heart, but its culminative effect should be remembered, and it should not be repeated too often, as cardiac failure might follow overstimulation.

Many times the patient being operated on is not kept warm enough. Moisture from wet towels and dressings are left to be evaporated by the latent heat of the body. During the winter months, in cold climates, at least, the operating room should be kept at 72 F., and with some cases it is best to have the operating table heated by coils of hot water circulating underneath the table. Shock is superinduced by draughts, and at no time during or after an operation should a patient be uncovered except the actual part to be operated on. The patient should be kept warm when going from the operating room to his private bed, which should be well heated before he is moved into it. In all our treatment, to bring about reaction, we should stop short of producing overaction and its sequence, which is secondary hemorrhage. Whenever it becomes necessary to operate on one who is very old it is important to reinforce their vital powers by a tonic course of strychnia a week or more before the operation, as it does much more good in this way than when given on the operating table. Confinement in bed is very damaging to these old people; they ought to be propped up in bed, or removed to a chair just as soon as it is practicable. It is important that operations on old persons be as bloodless as possible.

In these conditions of post-operative shock, do we not, under some circumstances, overtreat the case? Many times, with the heart scarcely beating for the lack of blood stimulation, with respiration sighing and shallow, with patient bathed in cold perspiration, we have seen one hypodermic injection after another containing stimulating poisons given in such quick succession that we may well pause to ask ourselves the question, are we not confusing and overpowering a circulation and respiration almost extinct by the rapid successive administration of such strong drugs as nitroglycerin, strychnia, digitalin, atropin and morphin into a subject already overpowered by a general anesthetic, loss of blood, shock and collapse? Under the excitement of such conditions, proper time very often does not elapse from one dose to another to see what the effect will be. Again, drugs having diametrically opposite effects are often used and stored up in the system. We are not claiming this to be a common practice in well-regulated operating rooms, but I am sure that many of us have witnessed cases in which the postoperative treatment was overdone.

It has always been my idea that, if surgeons would spend more time in getting the patient in proper condition to stand the operation, in having everything in readiness, in having assistants trained in what they are expected to do, and also if the least possible time were consumed in performing the operation, and if all lectures and explanations were suspended until the operation is finished, much less of the first necessary poison, viz., the anesthetic, would be required, and we would have fewer cases *in extremis* to deal with after operations.

THE MECHANISM OF STREPTOCOCCUS INFECTION.*

GUSTAV F. RUEDIGER, M.D.
[From the Memorial Institute for Infectious Diseases.]
CHICAGO.

[Work aided by a grant from the American Medical Association.]

INTRODUCTION.

Although a great deal of work has been done on the mechanism of streptococcus infection, both with normal and with immunized animals, many points are still left entirely in the dark. In the experiments described in this paper, an attempt is made to throw additional light on some of these points, but on account of the many inherent difficulties, the results which I have achieved by no means exhaust the problem.

Shortly after the publication of his classical paper on phagocytosis in daphnia, Metchnikoff[1] made a study of phagocytosis of streptococci in the human body, in cases of erysipelas. He concluded from his observations that streptococci gain entrance through abrasions of the skin, multiply and set up an inflammation. At the same time there is a gathering of microcytes about the streptococci, and these soon take up the latter and destroy them. Macrocytes also are found in considerable numbers, but they do not take up the streptococci, but have, nevertheless, a phagocytic action, in that they take up and remove dead and disabled microcytes.

In 1895 Denys and Leclef[2] studied the mechanism of immunity in rabbits which had been repeatedly injected with small but gradually increased doses of virulent streptococci. Their conclusions may be briefly stated as follows: Immune rabbit serum is not as good a culture medium for streptococci as normal serum, but it does not possess any marked streptococcidal powers. The cell-free fluid from a leucocytic exudate retards multiplication of virulent streptococci and sometimes kills them. Normal leucocytes in normal serum, and leucocytes from an immune rabbit suspended in normal serum, do not greatly retard multiplication of virulent streptococci. Leucocytes from a normal rabbit, or those from an immune rabbit, suspended in immune rabbit serum rapidly take up and destroy virulent streptococci. The serum has acquired something in the process of immunization which neutralized something in the cocci, by virtue of which they were protected against phagocytosis.

Denys and Marchand[3] showed that there is better phagocytosis of virulent streptococci when inoculated into a suspension of rabbit's leucocytes in normal rabbit serum, to which had been added 1 per cent. of immune horse serum, than when they were inoculated into the same mixture of leucocytes and rabbit serum, with the addition of 1 per cent. of normal horse serum.

Bordet[4] was able to find no protection against streptococci in normal and in immunized rabbits and guinea-pigs, except that due to phagocytosis. If a rabbit was treated with antistreptococcic serum, and later injected with several times the minimum fatal dose of streptococci, the organisms were all taken up by phagocytes and destroyed. In untreated rabbits he also found phagocytosis, but the organisms soon got the upper hand and the rabbit died of streptococcus infection.

Marchand[5] studied phagocytosis of virulent and non-virulent streptococci, and came to the conclusion that the failure on the part of the leucocytes to take up virulent streptococci depends on a physical property of the organisms and not on a secretion. Tchistovitch[6] injected rabbits intravenously with fatal doses of a highly virulent streptococcus, killed the animals in one-fourth to six hours, and examined the organs for evidence of phagocytosis. He was always able to find some phagocytosis in the lungs and in the liver of these animals, and concluded that this phagocytosis of virulent streptococci may be due to the fact that every culture contains some cocci which are less resistant than others, and that those are the only ones which are taken up by the phagocytes.

Simon[7] found very little evidence of phagocytosis *in vitro*, when rabbit's leucocytic exudate was inoculated with a non-virulent streptococcus. The washed leucocytes suspended in salt solution, and also the cell-free exudate, killed non-virulent streptococci, but not the virulent organisms. Leucocytic exudate mixed with rabbit serum had no effect on non-virulent streptococci. He was unable to confirm the view advanced by Bordet and others that a rabbit which is injected with streptococci into a pleural cavity containing leucocytic exudate can stand a larger dose than can a rabbit of the same size which is injected in the normal pleura. The pleural exudate was produced by the injection of aleuronat suspension forty-eight hours previously. These results are quite contradictory to those of other investigators, and it was, therefore, thought desirable to repeat these experiments with leucocytes.

EXPERIMENTS WITH LEUCOCYTIC EXUDATE IN VITRO.

A large Belgian hare was injected in each pleural cavity with 10 c.c. of aleuronat suspension, and bled to death in from eight to ten hours later. About 30 c.c. of thick exudate, containing chiefly polymorphonuclear leucocytes, was obtained and used in the experiment which is tabulated in Table 1. No sodium oxalate solution was added to this exudate, as this salt is strongly streptococcidal, but the coagulation of the exudate was prevented by occasional agitation of the tubes during the first hour. The contents of each tube were 2 c.c., which were inoculated with three loopfuls of a twenty-four-hour broth streptococcus culture, and three loopfuls were plated at intervals. Tube 8 differs from Tube 7, in that it contains the washed leucocytes which had been centrifugated out of 2 c.c. of the exudate, suspended in rabbit serum, whereas Tube 7 contained a mixture of 1 c.c. of the entire exudate +1 c.c. of serum. The fluid of the exudate in Tube 8 was removed to show that the effect of these mixtures is not due entirely to the liquid portion of the exudate, but in a large measure to the leucocytes. The table shows that non-virulent streptococci are destroyed by the leucocytic exudate, by mixtures of leucocytes and serum, by leucocytes and defibrinated blood, and by the cell-free exudate. Defibrinated blood and serum alone, the heated exudate and a suspension of leucocytes in salt solution have little or no effect on these organisms. The virulent streptococcus is not destroyed by the leucocytic exudate. Smears made from these tubes in from one to two hours showed evidence of phagocytosis, but this is most easily demonstrated in tubes containing suspensions of leucocytes in serum. Table 2 shows the same experiment as that shown in Table 1, except that guinea-pig's leucocytes and blood were used. With these leucocytes the eighteen-hour plates are often sterile, or nearly so, while it is only occasionally that they are sterile when rabbit's leucocytes are used.

TABLE 1.—Showing the effect of rabbit's leucocytic exudate and mixtures of exudate and body fluids on streptococci.

Streptococci.		Immediately.	3 hrs.	18 hrs.
300	Leucocytic exudate	4600	0	10000
300	Exudate 58° for half hour	3250	8000	Many
300	Cell-free exudate	4800	1400	3000
300	Defibrinated blood	4800	4700	Many
300	Blood 1 c.c. + exudate 1 c.c.	4000	750	1500
300	Rabbit serum	4200	4200	Many
300	Serum 1 c.c. + exudate 1 c.c.	5200	1100	Many
300	Leucocytes in serum	5000	900	Many
300	Leucocytes in NaCl sol	4900	5000	Many
324	Leucocytic exudate	420	11	Many
324	Defibrinated blood	430	7000	Many
324	Blood 1 c.c. + exudate 1 c.c.	750	540	Many
324	Rabbit serum	552	6500	14000
324	Serum 1 c.c. + exudate 1 c.c.	320	1	Many
B104	Leucocytic exudate	3500	3600	Many
270	Leucocytic exudate	1700	2	Many

Sources of streptococci: Nos. 300 and 324 from the heart's blood of scarlet fever patients, postmortem. No. B104 from an abscess in a guinea-pig which had been injected with a fungus. This organism has been passed through 78 rabbits and is very virulent for both rabbits and guinea-pigs.

TABLE 2.—Showing the effect of guinea-pig's leucocytic exudate and mixtures of exudate and body fluids on streptococci.

Streptococci.		Immediately.	3 hrs.	18 hrs.
300	Leucocytic exudate	6500	70	170
A	Leucocytic exudate	650	600	Many
B104	Leucocytic exudate	8000	10000	Many
300	Cell-free exudate	5500	800	6000
B104	Cell-free exudate	8000	10000	Many

300	Defibrinated blood + leucocytes	6800	240	72
300	Serum	6000	6000	Many
300	Serum + leucocytes	6000	2000	Many

Streptococcus No. 300 is not virulent for guinea-pigs. Nos. B104 and A are virulent. No. A was isolated from a peritonsillar abscess following an attack of follicular tonsillitis and was used in this experiment in the first generation on artificial media.

EXPERIMENTS WITH LEUCOCYTIC EXUDATE IN VIVO.

In order to determine whether a rabbit is more resistant when injected in a pleura containing leucocytic exudate than when injected in the normal pleura, the following experiments were carried out:

EXPERIMENT A.—A gray rabbit weighing 1,450 grams was injected into the right pleura with 7 c.c. of aleuronat suspension. Fifteen hours later 2 c.c. of a 40-hour culture of a virulent streptococcus were injected into this pleura and also into the right pleura of a normal rabbit weighing 1,500 grams. The normal rabbit was found dead in 18 hours, and the one which had been previously injected with aleuronat died 45 hours later.

EXPERIMENT B.—A gray rabbit weighing 2,100 grams was injected in the right pleura with 6 c.c. of aleuronat suspension. Eighteen hours later 1 c.c. of a 24-hour culture of a virulent streptococcus was injected into this pleura and also into the right pleura of a normal gray rabbit weighing 2,150 grams. The normal rabbit died in about 18 hours, while the aleuronat rabbit died only after 45 hours—21 hours after the death of the control.

The experiment was now varied so that the conditions were the same as in Simon's experiments.

EXPERIMENT C.—A rabbit weighing 1,700 grams was injected in the right pleura with 8 c.c. of aleuronat suspension, and 48 hours later this rabbit and a normal rabbit weighing 1,700 grams were each injected in the right pleura with 1 c.c. of a 30-hour streptococcus culture. In this experiment the aleuronat rabbit died in 24 hours, while the control lived for five days.

EXPERIMENT D.—A rabbit weighing 1,800 grams was injected in the right pleura with 9 c.c. of aleuronat suspension. Forty-eight hours later this rabbit and a normal rabbit weighing 1,800 grams were each injected in the right pleura with 1.5 c.c. of a 24-hour streptococcus culture. The normal rabbit died in 37 hours, while the aleuronat rabbit died in 45 hours—eight hours after the death of the control.

The results of the last two experiments agree fairly well with those obtained by Simon, and we may now ask why they are different from the results of Experiments A and B. Apparently, this difference is due to the fact that in Experiments C and D the inoculation was made some thirty hours later than in Experiments A and B. That this is the correct explanation is indicated by the following experiment:

EXPERIMENT E.—A rabbit weighing 2,300 grams was injected in the right pleura with 9 c.c. of aleuronat suspension. Forty-eight hours after this injection the rabbit was bled to death, and on opening the pleural cavity it was found to contain no leucocytic exudate.

Had this rabbit been inoculated in the right pleura forty-eight hours after the injection of the aleuronat suspension, the inoculation would not have been made into leucocytic exudate That being the case we would not expect that this rabbit could stand a larger dose of streptococcus than a normal rabbit. In Simon's experiments, however, the inoculations into the pleural cavity were made forty-eight hours after the injection of aleuronat, and this is probably the reason why he did not find these rabbits more resistant than normal rabbits. Had he made his inoculations within twenty-four hours after the injection of aleuronat his results would very probably have been different.

EXPERIMENTS WITH ORGAN CELLS.

It seems quite reasonable to suppose that the organ cells might play an important part in the protection of the body against invasion by streptococci, and with this point in mind the following experiment was carried out:

Experiment.—Two guinea-pigs, A and B, were bled to death and the blood collected under aseptic precautions. The organs were now carefully removed from the body, placed in sterile glass dishes and rubbed up; A with guinea-pig's serum, and B with defibrinated guinea-pig's blood. The organs and blood were not allowed to become cold. The suspensions of organ cells were now introduced into small test tubes, inoculated with two loopfuls of a 24-hour broth culture of a non-virulent streptococcus, and two loopfuls were plated at intervals. The colonies that developed in each plate were carefully estimated and the results are shown in Table 3. In no instance did the suspension of organ cells have an inhibitive effect on the multiplication of the streptococci, but on the contrary the organisms multiplied more rapidly in these suspensions than in either the serum or the defibrinated blood alone. If, however, bone marrow was added to the defibrinated blood or serum, the number of streptococci in these tubes was greatly diminished during the first three to five hours.

Table 3.—Showing the effect of suspensions of organ cells of guinea-pigs on streptococci.

Streptococcus.		Immediately.	3 hrs.	18 hrs.
B104†	Defibrinated blood	1800	1600	1500
B104	Blood + muscle	2000	8000	Many
B104	Blood + spleen	1900	Many	Many
B104	Blood + liver	1800	Many	Many
B104	Blood + kidney	1900	Many	Many
B104	Blood + adrenal	1500	Many	Many
B104	Blood + lymph gland	1500	6000	Many
300	Blood + bone marrow	2500	1000	Many
300	Serum	3800	3750	6000
300	Serum + leucocytes	2700	1800	1500
300	Serum + spleen	2800	5000	Many
300	Serum + liver	2000	12000	Many
300	Serum + kidney	2400	12000	Many
	Control liver + serum	0	3	9
	Control spleen + serum	0	0	0

†The strain of streptococcus B104 used in this experiment has not been passed through rabbits, and has lost its virulence.

These results agree with those found by Bail and Petterson[8] in their study of the mechanism of anthrax immunity in chickens, and show that suspensions of organ cells from the guinea-pig possess no streptococcidal power except the suspensions of bone marrow. Suspensions of marrow cells in defibrinated blood or serum kill large numbers of avirulent streptococci, but that is not the case with suspensions in salt solution. These results have also been obtained with suspensions of rabbit's bone marrow.

PHAGOCYTOSIS IN HUMAN INFECTIONS.

During the course of this work I had an opportunity to study a case of acute purulent rhinitis, in the discharge of which streptococci were found in pure culture.

Patient.—A man 27 years of age. During the first two days the discharge was clear and watery and contained very many streptococci in short chains and in diplococci. Figure 1 shows a photomicrograph of a smear made on the second day. There were only a few leucocytes, and those did not contain any streptococci. On the fourth day the discharge had become thick and purulent, and smears made at that time presented an entirely different picture. There were no free streptococci, but very many leucocytes, some of which were loaded with streptococci. Figure 2 shows a photomicrograph of such a preparation made on the fourth day. The purulent discharge continued for about a week, and during this time it was easy to find leucocytes in the smears which contained large numbers of streptococci. The streptococci finally disappeared, and the patient made a complete recovery.

In this case of streptococcus infection, phagocytosis of the organisms by the leucocytes seemed to be an important factor in combating the infection. In the smears made on the fourth day no free streptococci could be found, although diligent search was made for them. Plates made with a small quantity of discharge, which was obtained high up in the nares by means of a sterile cotton swab, contained, however, many colonies of streptococci after twenty-four hours' incubation. The fact that many colonies developed in the plates, although no free streptococci could be found in the smears, seems to indicate that the organisms were not dead when they were taken up by the phagocytes, but were taken up alive. It is possible, however, that there were free streptococci in this purulent discharge, even though they were not found in the smears.

PHAGOCYTOSIS OF LIVING STREPTOCOCCI IN VIVO.

The following experiment was, therefore, made to show more conclusively that there is phagocytosis of living streptococci in the animal body:

Experiment.—A guinea-pig was injected in the right pleura with 7 c.c. of aleuronat suspension. Twelve hours later he was injected in this pleura with 2 c.c. of an 18-hour glucose broth culture of a non-virulent streptococcus, and two hours after this injection he was bled to death. Several cubic centimeters of leucocytic exudate were now taken from the right pleura, under aseptic precautions. Smears made with this exudate contained no free streptococci, but many of the leucocytes contained cocci in large numbers.

Figure 3 is a photomicrograph of one of these smears showing streptococci in the body of a leucocyte.

Preparation of Slides.—By means of a sterile, soft cotton swab a small quantity of the exudate was now gently smeared on each of eight agar-covered slides; the slides were incubated in a moist chamber for from four to six hours, stained and examined under the microscope. The preparation of these slides requires the following special technic: Three ordinary clean glass slides and a heavy watch glass are placed in a large Petri dish and sterilized in dry heat. When the Petri dish has cooled sufficiently to be handled the slides are taken out with sterile forceps and hot glucose agar is poured on each to form a uniform thin film. Each slide is immediately replaced in the Petri dish and the agar allowed to solidify. The exudate which contains many streptococci in the bodies of the leucocytes is now gently smeared on these agar films, the watch glass is half filled with sterile water, and the large dish is placed in the incubator for from four to six hours. The water is used to prevent drying of the agar.

Staining.—The slides are now taken out of the Petri dish and dried in a thermostat at 55 C. for from fifteen to twenty minutes, or longer if necessary; fixed in 40 per cent. formalin for four or five minutes, washed in water, stained for only a few seconds with Loeffler's methylene blue solution, again washed in water and dried in the thermostat.

The best stains were obtained when the methylene blue solution was poured over the wet slide, the slide being held so that the stain ran off readily.

The slide is immediately placed in a dish of cold water and gently rinsed in several changes of water. Violent agitation in the water pulls off the film of agar. When the agar is perfectly dry (which requires only about half an hour), a cover-glass is placed on it, either in glycerin or Canada balsam. The slides are now ready to be examined with the oil immersion lens.

Examination.—Examination in various stages shows positively that the streptococci in the leucocytes multiply, burst open the cell and form a small colony surrounding the cell

---

8. Centralbl. f. Bakt., 1903, vol. xxxv, p. 102.

which contained them. Figures 4 and 5 are photomicrographs of such preparations at different stages. In Figure 4 the leucocyte has just been burst open and the streptococci are beginning to grow out of it; in Figure 5 a considerable colony has already formed around the ruptured leucocyte. These colonies may be found in all stages, by varying the time of incubation.

The leucocytes do, however, kill streptococci if the conditions are right, as is shown by the following two facts: 1. Organism No. 300 is not virulent for guinea-pigs, and we have seen that the leucocytes take up the cocci alive. The guinea-pig must destroy these organisms somewhere, and we can find no substance in its body that is capable of doing this except the leucocytes and the bone marrow. We have seen in Table 2 that the leucocytes destroy streptococci *in vitro,* and the inference is that they also destroy them *in vivo.* 2. Plates made with three loopfuls of the exudate when taken from the guinea-pig contained 2,540 colonies of streptococci after twenty-four hours' incubation, while plates made with three loopfuls, after the exudate has stood in a test tube in the incubator for six hours, contained only 480 colonies. Evidently some of the streptococci were killed in this tube, but the smears show that all of the organisms are in the leucocytes, hence they must have been killed in the leucocytes.

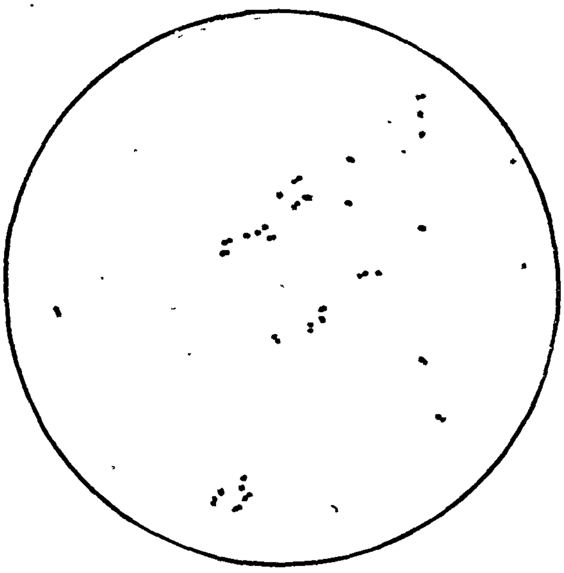

Fig. 1.—Photomicrograph × 1500. Streptococci in nasal discharge on second day of sickness.

THE SO-CALLED STREPTOCOCCUS TOXINS.

The so-called toxin-producing power of streptococci has been studied by a number of investigators.† In 1888 Manfredi and Traversa[9] succeeded in preparing a toxic filtrate from a streptococcus which had been isolated from a case of erysipelas. Four years later Roger[10] prepared a filtrate which killed rabbits in doses of 13 to 20 c.c. per kilogram weight of rabbit. Marmorek[11] got a more powerful toxin by growing a virulent streptococcus in a mixture of bouillon and human serum for three months and filtering. One cubic centimeter of this filtrate killed a large rabbit in three to four days. More recently he[12] recommends a special culture medium containing glycocol and leucin, in which he claims to have obtained powerful toxins. Marmier[13] got a powerful toxin by growing streptococci in peptone solution. He precipitated the toxin from the filtered cultures, and found that the precipitate killed rabbits in doses of 40 mg. Schenk[14] extracted the livers of rabbits which had died of streptococcus infection, with salt solution and filtered the extract. These filtrates and also those of a broth culture of his organism were toxic for mice. Homén and Laitinen[15] prepared a toxin from broth cultures by precipitation with ammonium sulphate. These cultures varied in age from three to thirty days, and apparently were not filtered, hence it is doubtful whether the precipitates were sterile. Lingelsheim[16] found that some strains of streptococci possess a high toxicogenic power, but that they usually lose that property after being grown on artificial media, even if they are passed through rabbits from time to time. He obtained his most powerful toxin from an organism of medium virulence.

Besredka[17] succeeded in preparing filtrates that are strongly hemolytic for red corpuscles of various animals, by growing a virulent streptococcus in heated rabbit serum for eighteen to twenty-four hours and filtering. His filtrates were not toxic for rabbits, but I have shown[18] that filtrates thus prepared may also be toxic. Simon[19] has pointed out recently that the hemolysin and the toxin are probably two different substances, and this may explain why my results do not agree with those of Besredka.

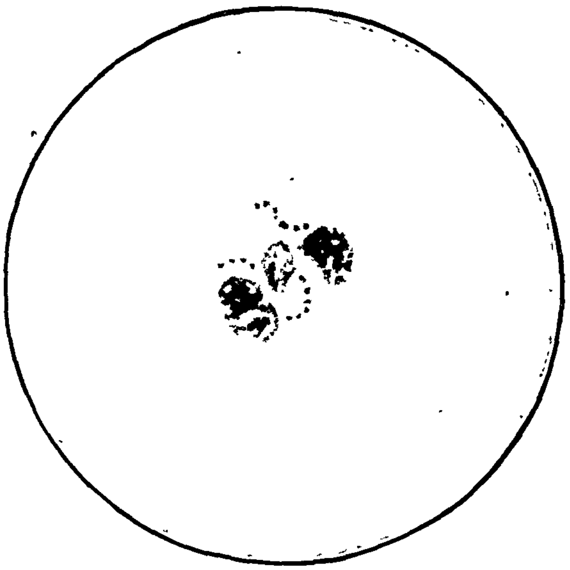

Fig. 2.—Photomicrograph × 1500. Streptococci in a leucocyte from nasal discharge on fourth day of sickness.

Arohnson[20] found that the filtered broth cultures, varying in age from two to fourteen days, possessed only weak toxic powers, even if the organism was highly virulent. Macfadyen and Rowland[21] prepared a highly toxic extract of streptococci by grinding up the organisms when frozen and reduced to a very low temperature by means of liquid air, and exhausting this mass witl salt solution. One-tenth c.c. of this extract killed guinea-pig in six hours when injected intraperitone

---

†It should be remembered that it has not yet been shown that any of the so-called streptococcus toxins correspond fully with the dogmatic definition now given of toxin.

HISTOLOGIC APPEARANCES.

On carefully dissecting out the gland and examining it with very low power it is found that the duct after leaving the vagina gradually increases in diameter in the vicinity of the gland. It then divides into secondary ducts, and these in turn divide, forming terminal ducts which drain the secretion from the lobules. The entire gland may be likened to a bunch of grapes, developed more on the one side than on the other. The main duct corresponds to the stem; the secondary and terminal ducts to the branches; and the lobules represent the individual grapes. Figure 3 demonstrates very well the gland as seen on section; *c* and *d* are cross or oblique sections of the secondary ducts and *a* is a well-defined lobule.

The duct near the vagina is lined with many layers of squamous epithelium, as seen in the central portion of Figure 4. As we pass toward the gland, the duct lining is composed of transitional epithelium, still many layers in thickness. In the deeper layers the cells are squamous in type, but in the superficial layer—the one directly in contact with the lumen of the duct—they are of the high cylindrical type. The secondary ducts are likewise lined by transitional epithelium (Fig. 6 at *b*). But the number of layers is usually much less, as seen in Figure 6 between *c* and *d*, and in Figure 4 at *A* and *B*. The terminal ducts may be lined by transitional epithelium, but I have usually found them covered by but a single layer of epithelium. Sometimes the cells are high cylindrical in type, as seen in Figure 6 at *e*. At other times cuboidal, as represented in the four terminal ducts depicted in Figure 5 at *a*. The glands forming the lobules are tubular or slightly racemose, are round or oval on cross section and are lined by one layer of high cylindrical epithelium (Figs. 4, 5 and 6). The cells, if filled with mucus, may be goblet-shaped (Fig. 14). The cell nuclei are small, round or somewhat flattened, stain deeply and are situated at the base of the cell. They bear a very striking resemblance to the cylindrical epithelium of the cervix. Their protoplasm does not, however, take the hematoxylin stain, as is so often noted in cervical epithelium While these small glands which make up the bulk of Bartholin's gland are for the most part confined to the lobules, isolated glands are found here and there opening directly into the main duct or into the secondary ducts, as shown in Figure 4 at *c* and in Figure 6 at *c*.

The elements of Bartholin's gland are held together by a definite connective-tissue framework rich in blood vessels and in non-striped muscle fibers. This tissue is, according to Muller, amply supplied with nerves.

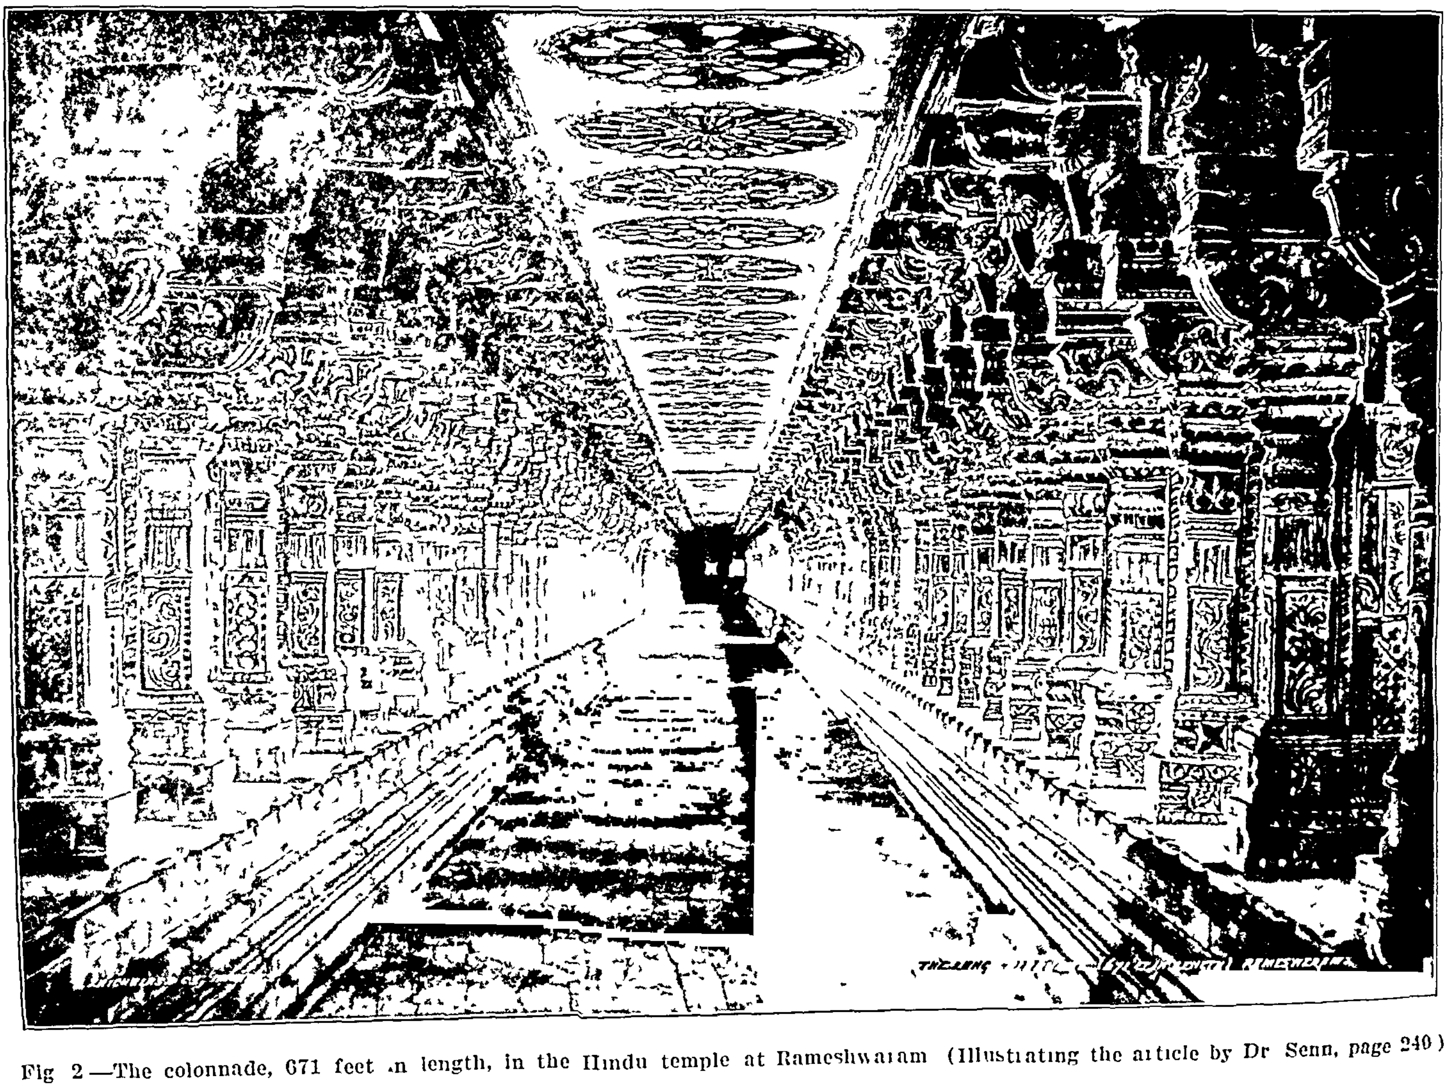

Fig 2—The colonnade, 671 feet in length, in the Hindu temple at Rameshwaram (Illustrating the article by Dr Senn, page 240)

CYSTS OF *BARTHOLIN'S GLAND.*

From the observations of Muller we learn that the duct of Bartholin's gland at its exit is about .5 mm. in diameter and that in the neighborhood of the gland it may be fully 2 mm. in caliber. It is readily seen that
any irritation producing [illegible] s might cause the two
sides o[illegible] duct [illegible] ued together, entirely
preve[illegible] contents. This fre-
quent [illegible] a gonorrheal in-
fectio[illegible] virulent charac-
acter, [illegible] low, but
if the [illegible] reten-

tion of the secretion and a cyst develops. In some cases the secondary ducts are blocked, while the main duct remains patent. We then usually have multiple cysts in the substance of the gland.

CYSTS DUE TO OCCLUSION OF THE MAIN DUCT OF BARTHOLIN'S GLAND.

These cysts are superficial (Fig. 2) and vary from 1 to 4 or 5 cm. in diameter; they are tense and rather thin-walled at their most prominent points (Figs, 8, 9 and 11). The body of the gland is pushed outward into the surrounding adipose tissue, as shown in Figure 2.

The cysts may contain a clear and limpid fluid, which is often viscid, but when hemorrhage has taken place from the cyst wall is yellowish or chocolate-colored.

The inner surface of the cyst is smooth, but here and there small round or sickle-shaped openings are seen in the wall. These are the points at which the secondary and terminal ducts open into the main duct. They have naturally become somewhat dilated, owing to the damming back of the section which can not escape. Sometimes the large secondary ducts become completely disconnected from the main duct, and they in turn give rise to secondary cysts, as seen in Figures 10 and 11.

The character of the cyst lining will, of course, depend on the situation of the point of occlusion. If this is near the vagina the cyst wall will be lined by a varying number of layers of squamous epithelium, while that portion of the cyst originating from the duct near the body of the gland will show a lining of transitional epithelium. At numerous points over the inner cyst surface the lining will consist of only a single layer of cells, of the high cylindrical or cuboidal variety. This is due to the unfolding of the small glands that here and there open along the course of the duct.

CYSTS DEVELOPING FROM OCCLUSION OF THE SECONDARY DUCTS OR THE TERMINAL DUCTS.

These are naturally much less common. They are multiple and very small. Their contents are similar to those of the larger cysts. Their lining is at certain points composed of transitional epithelium and at other points of one layer of cylindrical cells (Fig. 15).

CLINICAL HISTORY OF BARTHOLIN'S CYSTS.

The patient usually gives a more or less definite history of an old inflammation of the vagina which, after an interval of weeks or months, is followed by the development of a swelling low down in one or both vaginal walls. As a rule, this swelling is not very painful, but if bilateral, is frequently associated with discomfort on locomotion. Not infrequently a patient will enter a hospital for a peritoneal operation and a small cyst which has never given the slightest trouble is detected.

TREATMENT.

If the cyst occasions no inconvenience and is not increasing in size it may be left alone. If any operative interference be deemed necessary, it is well to dissect out the entire gland, taking care not to injure the large plexus of veins closely hugging the outer side of the cyst.

DETAILED REPORT OF CASES OF CYSTS OF BARTHOLIN'S GLANDS.

The following is a report of the cysts of Bartholin's glands coming under my observation at the Johns Hopkins Hospital during the ten years, 1893 to 1903. It is, however, no index of the number that exists, as the majority of the patients with this condition are treated in the dispensary and do not come to operation. It will be noted that the youngest patient was 17, the eldest 50. Bartholin's cysts are naturally most common during the child-bearing period. It will also be seen from the cases here tabulated that the smallest cyst was 5 mm. in diameter, the largest 4 cm.

Case 1 (Gyn. Path., 214).—Age 25. Cyst 1.5 cm. in diameter. The cyst wall was composed of fibrous tissue. The cyst was lined by one layer of high cylindrical pale staining epithelium with the nuclei at the base of the cells.

Case 2. (Gyn. Path., 490).—Age 43. Cyst 2.5 cm. in diameter. The walls were very thin and were composed of fibrous tissue; three definite cyst cavities were found. The glands were somewhat dilated, and the cyst lining was composed of one layer of high cylindrical or cuboidal epithelium.

Case 3 (Gyn. Path., 2951).—Age 38. Cyst 2.5 cm. in diameter. The cyst wall was of non-striped muscle and fibrous tissue. Typical Bartholin glands were found in the cyst wall, also sections of secondary ducts. The cyst lining was of columnar or cuboidal epithelium. Where it was two layers in thickness the deeper layer was cuboidal, the other cylindrical. This cyst was evidently due to dilatation of the duct, with secondary unfolding of the glands.

Case 4 (Gyn. Path., 2971).—Age 44. Cyst 5 mm. in diameter. The walls were composed of fibrous tissue. The cyst lining varied in different places, one layer being of cylindrical epithelium, several layers with the superficial cells cylindrical; several layers of squamous epithelium dipping into the stroma, or one layer of cylindrical epithelium.

Case 5 (Gyn. Path., 3133).—Age 50. The cyst wall was composed of fibrous tissue and had glands scattered throughout it. The cyst lining varied; in places there was one layer of epithelium; at other points two layers, with a superficial layer of cylindrical cells; here and there the epithelium was many layers thick.

Case 6 (Gyn. Path., 3352).—Age 35. The cyst was 3x3x2 cm., and very thin walled, translucent; on the inner surface there were several smaller semilunar depressions, evidently where other small cysts had opened into the larger one. The cyst wall was of fibrous tissue, with glands in the wall, and the cyst lining consisted of one or two layers of epithelium, the superficial layer of which was composed of cuboidal cells.

Case 7 (Gyn. Path., 3527).—Cyst 1.5 cm. in diameter; the walls were 1 mm. thick, transparent; there were small round or semilunar openings on the inner surface, indicating remnants of smaller cysts which had opened into the larger one—dilated secondary ducts. The cyst wall was of fibrous tissue, with some non-striped muscle; the greater part of the gland structure was forced to one side—one gland .5 mm. in diameter, one secondary duct 1 mm. The cyst lining was made up of from 2 to 8 layers of transitional epithelium; superficial layer cuboidal. The cyst had evidently developed in the duct.

Case 8 (Gyn. Path., 3594).—Size 2.5 cm. The cyst wall was of fibrous tissue; at one end was a large amount of normal gland tissue; some glands were dilated to 3 or 4 times the natural size. A few secondary dilated ducts were seen. The cyst lining consisted of from 2 to 10 layers of epithelium; the superficial layer of which was cylindrical. This was evidently a cyst of the duct.

Case 9 (Gyn. Path., 3910).—Age 26. Cyst 4 cm. in diameter; the walls thin and translucent, the inner surface smooth, with here and there round or sickle-shaped spaces indicating openings of dilated secondary ducts. The cyst wall was composed of fibrous tissue. The cyst lining consisted of one layer of cuboidal or almost flat cells; at places there were 10 or more layers of swollen, pale staining polyhedral cells. This patient had tubercular peritonitis.

Case 10 (Gyn. Path., 4345).—Age 35. Cyst 1 cm. in diameter. The cyst wall was of fibrous tissue and the cyst lining of from 2 to 10 layers of transitional epithelium; the superficial layer being cylindrical and apparently ciliated.

Case 11 (Gyn. Path., No. 4444).—Cyst 2x1.5 cm., transparent. The cyst wall was of fibrous tissue, containing gland structure, mostly normal, a few glands from three to four times the natural size, with flattened epithelium. The cyst lining was of from two to eight layers of transitional epithelium, the superficial layer being cylindrical. This was a cyst of the duct.

Case 12 (Gyn. Path., 4535).—Age 35. Cyst 4.5x3x3 cm., egg shaped, thin walled, transparent, and showing on the inner surface several small, shallow, sickle-like openings of the dilated secondary ducts. The cyst wall was of fibrous tissue; the gland elements were mostly normal, a few dilated. The cyst lining, in some places, consisted of one layer of high, pale staining cells, side by side, transitional epithelium from 2 to 6 r more layers thick. Unfolding of ducts and glands.

Case 13 (Gyn. Path., 4643).—Age 23. Size 7 mm. The cyst was situated in the left labium and was very hard.

Case 14 (Gyn. Path., 5019).—Age 39. Cyst 3 cm. in diameter. The cyst wall was of fibrous tissue, and the cyst lining was composed of one layer of cylindrical epithelium.

Case 15 (Gyn. Path., 5174).—Age 34. Cyst small. The cyst wall was of fibrous tissue, and the cyst lining was made up of one layer of columnar epithelium, with the nuclei at the base of the cells.

Case 16 (Gyn. Path., 5250).—Age 17. The cyst wall was of fibrous tissue and the cyst lining was composed of several layers of transitional epithelium; at some points there was one layer only.

Case 17 (Gyn. Path., 5509).—Age 25. Cysts very small, multiple. The cyst wall was mostly of gland tissue; there were a few cysts varying from a pin point to 2 mm. in diameter. The cysts were mostly dilated secondary ducts, lined in part by transitional epithelium, and in part by one layer of cylindrical epithelium.

SOME NEW VIEWS RESPECTING THE HOROPTER.*

GEORGE T. STEVENS, Ph.D., M.D.
NEW YORK.

No question in physiologic optics has been more attractive to investigators in that department of research than that of the horopter, yet. although the ablest thinkers have devoted themselves to it with great earnestness, the subject has remained an unsolved enigma. That the doctrines and theories which have been advanced have not solved the problem, no one who has studied it can doubt. The most notable of all these doctrines, that of the great master Helmholtz, is as unsatisfying, if not more unintelligible, than the others. So far as his marvellous array of abstruse mathematical formulæ served to indicate even a single horopter it was an impossible one both in form and position.

If we inquire into the cause of the failure to solve this interesting and, as I believe, this most important problem, we shall find that it is due to a misunderstanding of the two fundamental principles on which any doctrine of horopters must be formed.

These two principles are: 1. The doctrine of corresponding points. 2. The doctrine of the directions of the meridians of the retinas.

The first of these principles has been stated incorrectly by all investigators alike, while the second has been incorrectly affirmed by Helmholtz, and those who have accepted his conclusions drawn simply from his own peculiarities.

We have, then, first of all to examine these two fundamental principles.

The doctrine of corresponding points as stated by Helmholtz, who expresses *the generally accepted view*, is as follows:

1. "On apparent vertical concordant lines, points which are at the same distance from the vertical horizon are concordant."

2. "Points, which in the retinal horizons are at equal distances from a point of fixation, are corresponding points."

Le Conte expresses the law by saying that if a pair of dividers is opened until they are the exact distance apart of the central spots (maculæ) and, while being held level, touch many points, all these points are corresponding points.

Helmholtz proceeds to show that the corresponding points in the two visual fields are also at the same height and separated by the same *angle*. He illustrates his proposition by stereoscopic and other diagrams which are drawn on a flat surface.

It requires but a *moment of consideration to* discover that there is here a marked inconsistency.

If points equally distant in the plane of the visual field, as represented by these flat surfaces, are corresponding, as Helmholtz asserts and proves, then it is impossible that points equally distant in the retinal fields should also be correspondent.

Every proof that Helmholtz brings to sustain his interpretation of the law of corresponding points is positive evidence of the incorrectness of his view and the view which has been universally accepted.

If then, the accepted view is incorrect, what is the correct statement of the law? Accepting the law that points in the plane of the visual field, which are at equal distances and separated by equal angles are corresponding points in the visual field, it is at once apparent that the retinal corresponding points must be variable in distance depending on their relative distances from the points of fixation, the muculæ.

I have elsewhere defined corresponding points of the retinas as "those points in the retinas which answer to proportional degrees of rotations of the eyes about the centers of rotation." They represent, therefore, the relation between the muscular and the retinal senses.

The belief that for retinal spatial locations equal distances in space must be impressed on equally distant points of the retina is an entirely false conception of the functions of that organ.

That some recent observations have appeared to show that estimation of space may be, within very limited extents, made without corresponding movements of the eyes, does not invalidate the proposition that the corresponding points of the retinas represent the relation between the muscular and retinal senses. We shall *presently see that another element enters into the ideas* of space which emphasizes the psychologic side of the question to the modification of the purely mechanical side.

The second fundamental principle in the question of the horopter is the position of the meridians of the retina relative to the cranium.

Helmholtz, examining by a method not fully reliable, found that, as he believed, the vertical *meridians* of the retinas leaned outward, while the horizontal meridians remained exactly horizontal. This does not permit of a discussion of this proposition or the reason for these apparent peculiarities. I have elsewhere shown the probable reason for this error. It is sufficient to say that the conditions of adjustment of the great philosopher's eyes, which he has incidentally revealed, confirm the *belief that his meridians leaned out, but there is no reason* to suppose that his observations on his own horizontal meridians were correct. There is every reason to believe that they were erroneous.

---

* Read in the Section on Ophthalmology of the American Medical Association, at the Fifty-[illegible] Annual Session, June, 1904.

The leaning out of his vertical meridians did not, as he assumed, represent the typical adjustment of eyes; they were, in fact, rather exaggerated instances of an anomalous state.

The clinoscope has cleared this subject of all mystery and shows that there are various anomalies of the positions of the vertical—and, therefore, of all—meridians just as there are various anomalies of refraction. But the typical position for the vertical meridians is precisely vertical.

Now, assuming the law of corresponding points as I have stated it, and assuming the verticality of the vertical meridians, the necessity for all the involved and almost endless mathematical formulæ of Helmholtz in determining a horopter is eliminated and these intricate formulæ may be replaced by simple problems of plane trigonometry.

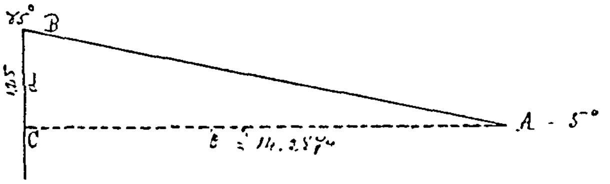

Fig. 1.

The horopters of former investigators have been based on a doctrine of corresponding points of equal measurements on the surface of the retina. The horopter, according to the present reasoning, is based on corresponding angular displacements which vary in the two eyes in proportion as a given object in the visual field is removed to one side of the point of fixation.

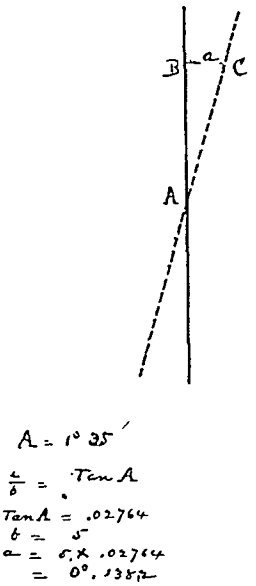

Fig. 2.

With the data at our command derived from these two basal principles, we may then compute a horopter when the eyes are directed straight forward to a point at infinite distance, the head being in the primary position, but for other positions further data are demanded. In convergence, and with depression of the plane of vision, the phenomena arising from the laws of torsions must enter into our computations.

For example, if the two eyes are in convergence and the plane of regard is depressed the horizontal meridians of each eye will tilt downward toward the temporal side, and the upper end of the vertical meridians will tilt out while the lower ends will tilt in. These tiltings in typically adjusted eyes are accurately proportioned to the lateral and ascensional displacements of the eyes. Here permit me to diverge from my topic long enough to allude to the absurd custom of some writers who confound the two absolutely different and independent conditions, torsions and declinations, the first physiologic rotations, the other anomalous adjustments.

Employing all these data we are then in position to determine the general positions of a horopter for different adjustments.

In the case we have already supposed, with the eyes directed to the horizon and at infinite distance, the horopter will be formed in relation with the distant point of fixation and will be a plane surface at a right angle to the plane of regard. If we were to accept only a purely mechanical interpretation of visual phenomena, in this case all objects nearer than the point of fixation would be excluded from the horopter. As a matter of fact there is a subjective horopter, formed on the basis of such unconscious conclusions as enter into the experiment of Dove, where distinctly heteronymous images are seen not only single but correctly located as to distance.

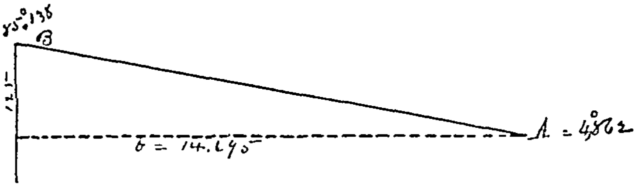

Fig. 3.

The subjective horopter is of the utmost importance, and is governed by fixed laws. The physical horopter, including the points in space actually impressed at corresponding points of the two retinas may be regarded as the skeleton, while the subjective horopter, including points in space which are impressed at such points on the retinas as correspond to a demand for certain exact movements of the eyes necessary in order to place the image at the macula of each eye constitute a mental assemblage of the lineaments of harmonic visual impressions. In a rude way we may compare this subjective horopter to the overtones of a musical sound. The fundamental tone by itself is not pleasing; it is noise. It is the skeleton of the tone. But when combined with its multiplicity of overtones, tones which even the ear of the expert musician fails to differentiate, the musical tone finds its body and affords pleasure to the listener.

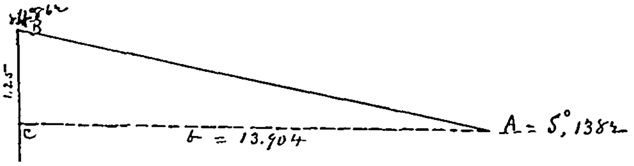

Fig. 4.

In the subjective horopter the consciousness of the required movements takes the place of the actual movement as it does in the Dove experiment.

This doctrine of a subjective horopter does not by any means provide for a confused jumble of space perceptions either in the retinas or in the mind. Every object in the subjective horopter is as much subject to the laws of the angular valuation of muscular movements as are the objects in the physical horopter. Keep in mind the principle that while the image of a given point in space may fall on physically non-corresponding points of the retinas, a subliminal consciousness determines the relative positions of these two non-corresponding points to the maculæ of the two eyes and concludes on the movements which would be demanded to make an actual adjustment for the maculæ were such movements to be executed, and it is this unconscious conclusion, based on accurate data, that places the object, singly, in its appropriate position in the field of view and at the proper distance relative to other objects in that field.

In our horopter, objects less distant than the point of fixation may still be within this subjective horopter, their images being impressed on the two retinas at corresponding points for the lines of incidence on one or other side of the maculæ. Then they will appear, as in the spark in the Dove experiment, as single. The principles controlling the psychic phenomena in that experiment are, in this case, modified to meet the different conditions. Thus, a great number of objects within a fairly wide range may be brought within a perfect horopter.

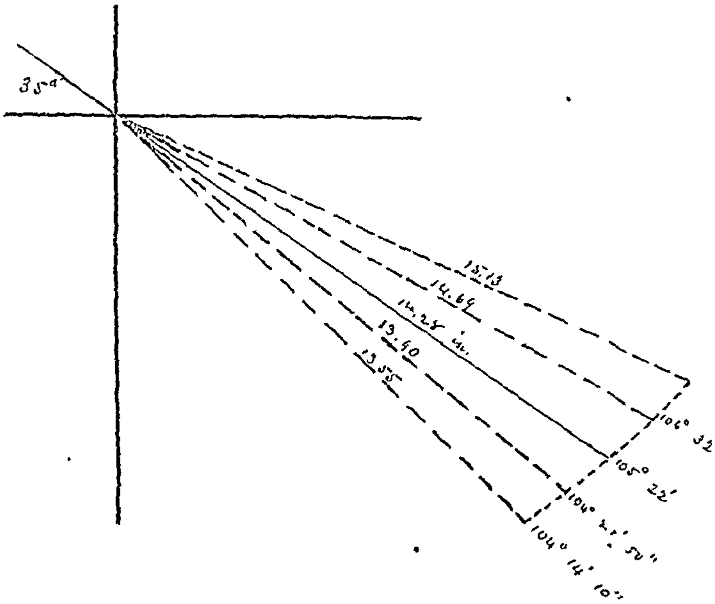

Fig. 5.

If the direction of the gaze is changed while the head remains in the primary position a new horopter must be and is formed.

Let the gaze be directed downward and to a point a few feet distant. The torsional element is so slight that the former calculations will very nearly give the position of the horopter. Should, however, the gaze be fixed on an object, as for example, the page of a book held in the ordinary position of reading, say, with the point of fixation in the median plane, the plane of regard depressed 35 degrees, *and with the lateral deviation of the visual* lines (the convergence) for each eye 5 degrees, while the distance between the nodal points is assumed to be 2½ inches, the problem becomes more complicated. We may determine, from these data, the distance of the horopter and, taking the torsions into consideration, the position of that horopter relative to the plane of regard.

The distance of the point of fixation from the base connecting the two nodal points is determined by the formula, b/a=Cot A, in which A=5° (the lateral angle), a=1.25 (½ the base line) and b the distance required (Fig. 1).

This distance is found to be 14.2875 inches, and at this distance the image of the point of fixation is exactly at the macula of each eye.

Images of points in the horizontal line passing through the point of fixation on the page require special consideration here, and there enters at once an apparent difficulty, for the horizontal meridians of the two retinas are no longer horizontal by the law of torsions. If we consult *Helmholtz's table of torsions we find that* the horizontal (and vertical) meridians have, by a convergence of 5° in each eye and a depression of the gaze of 35°, *been tilted,* the horizontal with the outer part down and the inner part up to the extent of 1°35'.

Is it possible now for the images of points of a horizontal line on the page to be impressed at the horizontal *meridians of the two* retinas, seeing that the former is *exactly horizontal and the latter are tilted?*

It is not only possible, but in fact exactly because of this tilting of the retinal meridians, that the images of points in the horizontal line of the visual field will be impressed precisely at the horizontal meridians of the retinas.

Without *giving space to the* mathematical demonstration of this statement, we pass to inquire in what position will lie a horopteric line running up the page and through the point of fixation.

Let us select a point of 5° above and another 5° below the point of fixation for the determination of the direction of this ascending line.

It has been shown that the point of fixation is distant from the base line 14.2875 inches. Will the distances to the points 5° above and 5° below be the same? Evidently not, for, in order that the image of the upper point on the page shall be impressed at the vertical meridians, the angle of incidence must be less, since owing to the tilting of the vertical meridians they are less widely separated below the maculæ (where the upper image is impressed) than at the maculæ; and because the vertical meridians separate above the maculæ the angle of incidence from the lower point will be greater.

Taking these facts with the given data, we find first the actual extent of the spreading at a point 5° above the macula. This is determined by the formula, a/b=Tan A, in which A=1°35', b=5° and *a* is the distance through which the point B has been moved to C (Fig. 2) by the act of torsion.

The extent of change of position outward of this point then is, by the formula, 0°,1382. Hence, in determining the distance of the upper selected point we must subtract from the lateral angle of 5° the extent of the removal of the point B, or 0°,1382. Also for determination of the distance of the lower selected point, we must add, 0°,1382 to the 5° (Fig. 3). Then by the first formula, b/a=Cot A, in which A=4°,862, or 5°,1382, we obtain the distances 14.695 inches for the upper selected point, and 13.904 inches for the lower. Connecting these through the point of fixation we have a line representing the horopteric line running up the page of the book which will form an angle above the line from the fixation point of 105, which represents also the angle at which the book should be held in order to form a perfect horopter under the conditions given and with typically adjusted eyes (Fig. 4).

If these calculations are carried further, it is found that in the space of 10° up and down the page there is a very slight curve, as is shown by the diagram (Fig 5).

Experimental research has fully confirmed the results of these calculations.

:hange in the

.ll currents of fresh

ge will banish the in-

The principles which have been shown in these calculations may be applied to any other line in the field of what may be called the objective horopter, while the innate conception of the comparative relations of objects not in this objective horopter serves for the formation of the subjective horopter.

A horopter will be formed in relation to every point of fixation and with as strong, if not with a much stronger, impulse than that of accommodation. Difficulties will be overcome when possible, at the expense of much effort and the habitual failure to make such adjustments of the eyes as to form a fairly complete horopter is attended by unpleasant and even serious results.

The horopter then, is not the over-refinement of scientific curiosity. It is a practical, even momentous subject worthy of the most earnest consideration.

In what has been said it has been assumed that the adjustments of the eyes are typical. Unfortunately such adjustments are not only not universal, but anomalous conditions of adjustments are of great frequency.

Such anomalies may serve as slight hindrances in the formation of a horopter or they may absolutely prevent it. In either case, the instinct to conquer the difficulty is present and efforts are made to overcome the obstacles

In order to illustrate this proposition let us take ou supposed case of one reading with a convergence of th eyes of 5° each, with a depression of the plane of rega of 35°. If there is perfect adjustment of the eyes t' horopter is formed as we have shown.

Suppose, however, that the person thus engaged the book has an adjustment of the eyes of 10° of higher than the typical adjustment: such cases are rare, they are, on the contrary, very common. Cons what must occur. This person must depress the of regard, not 35°, but 45°. But with a converge 5° each eye, and a depression of 45° the torsion longer 1°35′, but much more, therefore no horopte be formed if the head of this reader remains in th position as that of the person at first supposed contingencies present themselves, the field of vie remain confused or the reader may advance th 10°. This he prefers to do, and by this means promise is made by which a fairly good horopte tained. The same person advances the head walking or in conversation.

But suppose again that this person has the justed too low by 10°; in such a case no horopte formed at the proper position. It can be done b ing the head backward. We see these people w chins in the air everywhere.

Again, the reader may have anomalous dec and here an obstacle to the formation of the is interposed and the anomalous adjustment ferred to may be and often are complicated w alous declinations.

Are these and other maladjustments simpl n- iences? They are, on the contrary, conditio eat moment.

Let us recall the person with the eyes a too high and who throws the head forward in or orm a horopter. It is in this class that we find th ump- tive. It is no accidental coincidence. The ptive is, in almost all instances, a person who has e mal- position of the air passages induced by th omatic efforts to form the horopter, restricted the ation of air in the upper bronchi and has thereby d a hospitable welcome to the bacillus of consump I speak from experience when I say that if befo e ravages of the parasite have become too extensive pose of the

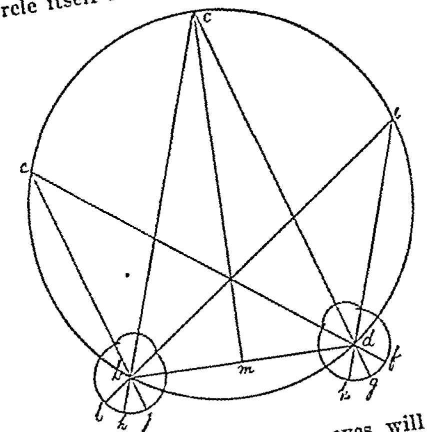
DISCUSSION.

AGE, Nashville, Tenn.—I will be able to prove, is illustration, that corresponding retinal points ilarly related to the two maculas, not by linear but in degrees of arc. All are agreed that with ons the macula of one eye corresponds with the he other eye. I had thought that we all likewise t Helmholtz was right when he taught that all other ding retinal points bear a similar relationship to las. If Helmholtz had correctly constructed his hor- would have had at hand a mathematical proof of the ness of his statement. The true horopter, the isogonal or the monoscopter, is constructed through the point of and through the centers of rotation of the two eyes. three points, as shown in the illustration, are c, b and d the circle itself is c-a-b-d-c. Every point on this circle



capable of throwing light into the two eyes, will be seen singly by the two eyes, for the images will fall on retinal points that correspond. In the illustration the visual axes h-c and g-c and the indirect visual lines j-a, f-a, l-e and k-e all lie in the plane of the circle a-b-d-e-c. It is evident that this plane prolonged backward would include the horizontal retinal meridian of each eye. The arc l-j is a part of the one horizontal retinal meridian and the arc k-f is a part of the other horizontal retinal meridian. The macula in one eye is at h and in the other eye is at g. The macula h corresponds with macula g,

used.

The principles which have been shown in these calculations may be applied to any other line in the field of what may be called the objective horopter, while the innate conception of the comparative relations of objects not in this objective horopter serves for the formation of the subjective horopter.

A horopter will be formed in relation to every point of fixation and with as strong, if not with a much stronger, impulse than that of accommodation. Difficulties will be overcome when possible, at the expense of much effort and the habitual failure to make such adjustments of the eyes as to form a fairly complete horopter is attended by unpleasant and even serious results.

The horopter then, is not the over-refinement of scientific curiosity. It is a practical, even momentous subject worthy of the most earnest consideration.

In what has been said it has been assumed that the adjustments of the eyes are typical. Unfortunately such adjustments are not only not universal, but anomalous conditions of adjustments are of great frequency.

Such anomalies may serve as slight hindrances in the formation of a horopter or they may absolutely prevent it. In either case, the instinct to conquer the difficulty is present and efforts are made to overcome the obstacles.

In order to illustrate this proposition let us take our supposed case of one reading with a convergence of the eyes of 5° each, with a depression of the plane of regard of 35°. If there is perfect adjustment of the eyes the horopter is formed as we have shown.

Suppose, however, that the person thus engaged with the book has an adjustment of the eyes of 10° of arc higher than the typical adjustment: such cases are not rare, they are, on the contrary, very common. Consider what must occur. This person must depress the plane of regard, not 35°, but 45°. But with a convergence of 5° each eye, and a depression of 45° the torsion is no longer 1°35′, but much more, therefore no horopter will be formed if the head of this reader remains in the same position as that of the person at first supposed. Two contingencies present themselves, the field of view may remain confused or the reader may advance the head 10°. This he prefers to do, and by this means a compromise is made by which a fairly good horopter is obtained. The same person advances the head also in walking or in conversation.

But suppose again that this person has the eyes ad-
jused too low by 10° ; in such a case no horopter can be

A stained specimen from the same subject, no matter how careful the technic employed, invariably failed to show anything.

But little was learned regarding the mode of conveyance of the infection owing to the comparative rarity of the anopheles we were compelled to make use of various species of the culex:[9] *C. consobrinus* (Desv.) *C. stimulans* (Walk.), *C. tarsalis* (Coq.), and *C. tæniorhynchus*, the *Conchyliastes posticus* (Wied.) and the *Stegomyia fasciata*.

Young but well-grown insects of the above genera were taken from the breeding jars and allowed to feed on dengue patients. Each group was then confined in a separate cage for periods of time varying from five to fourteen days, then taken out and carefully dissected on a glass slide.

---

[9] Howard's classification of species is used.

The stomachs and salivary glands were then examined, both directly and after being treated with a solution of sodium chlorid and various simple stains. No bacteria, piroplasma or zygote forms were found.

The inoculation experiments were unsatisfactory and open to criticism, for the volunteer subjects were not only exposed to the bites of other mosquitoes at any time, but they were also brought into almost daily contact with dengue cases.

Case 1.—Bitten by *Culex tarsalis* and *Culex consobrinus* that had been allowed to feed on a 4-day dengue patient 10 days previously. No fever appeared in 14 days.

Case 2.—The experiment was repeated with similar virgin insects that had fed on first, second, third and fifth day patients and that had then been allowed to remain in isolation for from 8 to 14 days. The man bitten by the fifth-day mosquito was taken down with typical dengue 6 days later.

Case 3.—Bitten by a similarly infected stegomyia which had been isolated 14 days previously. Patient, fourth day. An attack of dengue followed, but not until two full weeks had elapsed.

Case 4.—The same procedure was carried out with a young *Culex stimulans* which had been infected 11 days prior to the experiment from a 3-day case. No infection resulted.

Other sources of a possible origin for the epidemic were investigated. Scheube[10] and Clayton[11] have fully overed the essential meteorologic factors in a few brief hrases: high temperature, moisture, low levels, lack of air space, dirt and overcrowding.

So many cases had catarrhal symptoms of the respiratory tract (bronchitis, pharyngitis, tonsillitis and coryza) that it seemed to be more than a coincidence and strongly suggested the epidemic fevers of overcrowding so frequently seen on shipboard.

The striking resemblance to influenza is also seen in the leucopenia and the selective action of the toxin on the nervous system. Many who did not complain of pain or soreness in the throat had marked congestion, with white patches, or even ulcerated areas, of the pharyngeal mucous membrane, and the peculiar putrefactive odor observed in cases of epidemic catarrh was characteristic of these cases also.

f that xtremely interesting to carry through
The especially on blood serum and blood-
onnec the blood, enlarged glands and
ormul mplicated cases.

The appended table of urine examinations shows decided increase in phosphates. They often appeared as a heavy cloud in freshly voided specimens. No experiments were made at the time to see if clear urine would have resulted from the previous internal administration of acids. The amount of urine passed in twenty-four hours was decreased. Albumin was hardly more than a trace when present. Two cases in which it appeared were atypical ones in the early part of the epidemic.

The estimation of phosphates, sulphates and chlorids was made by the use of the centrifuge. The urea was measured by the modified Davy's method and is open to criticism, as the low percentages of the first group were probably due to lime employed not being so good as that obtained later.

The urine in 122 cases of dengue gave albumin in six instances, about 4.9 per cent. In 41 cases of malaria it was found five times, or 12.2 per cent.

Our conclusions are as follows:

1. Dengue is one of the few fevers in which a leucopenia persists from the first.
2. Blood examinations are of great value in differentiating between malaria and dengue. Even though no parasites be found, a slight leucocytosis with decided increase in the percentage of large mononuclears and transitionals is indicative of the former, while a leucopenia, with a normal differential leucocytic count or varying degrees of a small mononuclear lymphocytosis and a marked eosinophilia late in the disease, is characteristic of the latter.
3. Albuminuria is seldom seen in an ordinary attack of dengue, and then only in small amounts. The exact opposite is true of yellow fever.
4. The period of convalescence in dengue is almost invariably ushered in by a pronounced small mononuclear lymphocytosis which persists for several days.
5. It is suggested that the causative agent is a small diplococcus or a delicate bipolar staining bacillus closely resembling Pfeiffer's organism. It is probably transmitted by the respiratory tract, and its virulence is much increased by the presence of the essential meteorologic factors and by overcrowding.

CINCINNATI, OHIO.

This case was referred to me by Dr. J. C. Oliver of Cincinnati, with request for examination and opinion.

Patient.—The subject of the conditions here reported was a teacher, 51 years of age, married, and the father of three healthy children, aged, respectively, 20, 18, 11.

I saw him at the Presbyterian Hospital, Cincinnati, in March, 1904. He was about 5 feet 10 inches in height, well developed, fairly nourished, of dark complexion and hair. Not evidently anemic. Family and personal history good.

Present Illness.—His chief complaint was of headache, which was located in the occipital and both mastoid regions; it was dull in character and had persisted since its onset, five weeks before. He also complained of inability to close either eye, which was evident.

The onset of his trouble he attributed to an attack of alleged la grippe, five weeks previous, manifested by sneezing, chilliness and malaise. He kept at his work, however, for two weeks, then took to his bed for about two weeks. There was no facial or other paralysis up to this time. He then went on a journey of 50 miles by rail, and the next day noted that he could not close his right eye. Three days later there was inability to close his left eye.

---

* Read in the Section on Nervous and Mental Diseases of the Medical Association, at the Fifty-fifth Annual Session,

Examination.—Three days after this he came under my observation and presented the following conditions: Patient in bed. Complete paralysis of both facials, upper and lower divisions, inability to close either eyelid. The eyeballs rolled up and outward when he attempted to close the lids. He could not wrinkle forehead, frown or smile. The lower lip drooped and could not be approximated to the upper, giving to the face an idiotic expression strangely at variance with the intelligence of the patient as manifested in his conversation. He could protrude his tongue well and move it in all directions but could not roll it up to form a longitudinal gutter: an interesting confirmation of the supposition that the tongue is supplied in part by the facial as well as largely by the hypoglossal.

His speech was blurred, owing to the defective lip movements, with some difficulty in swallowing, especially liquids.

As regards the other cranial nerves: The ocular movements and pupillary reactions were good. The masseters and temporals acted well. The mouth felt to him unduly dry

Hearing was defective, watch tick heard at one inch (This, he states, is an old defect.) He hears voices well He could open his mouth forcibly against resistance. There was some tenderness on pressure in front of both mastoid processes

Motor power in the trunk and extremities was good Grasp, right, 105; left, 90 (normal). No evident muscular tremor or wasting. Sensation to touch, pain and temperature impressions were good.

Reflexes: The knee-jerk, March 7, was absolutely absent on both sides, even to re-enforcement. Plantar reflexes present and active, flexor in type. Visceral reflexes were normal. Vasomotor and trophic: There was free sweating of both legs from the knees down, without obvious cause.

Subsequent History.—Three days later, March 10, he came for further examination. He walked well but felt weak.

Pulse 72, of fair quality and volume. Heart clear, Grasp, right, 100; left, 95. Legs still sweating excessively

Face still paralyzed, both sides, upper and lower divisions.

Taste absent on right side to salt, sweet and bitter. Present on left side, but dulled and uncertain The knee-jerks had returned and were equal, but considerably reduced.

Four days later, March 14, he walked to my office, nine blocks; said he felt a little confused in his head, but did not indicate it in thought or action. Pulse 72, fair tension.

He could raise the right eyebrow slightly and draw the right angle of mouth slightly upwards. He could not close the eyes completely. Could not taste sweet on right or left sides of tongue. Calls bitter "sour" and salt "sour" on right side. Speech was better and food and liquids were managed with little difficulty.

Treatment.—The first electrical tests were made at this time. To faradism all facial muscles responded, very sluggishly. To galvanism, less sluggishly, but not quickly. Kathodal contraction was greater than the anodal contraction.

The knee-jerks were present, equal, and stronger than four days before, but not fully normal. At this period the patient decided that his interests demanded his return home.

Addendum.—A letter from the patient, dated August 12, 1904, states: "My recovery has been nearly complete, though when very tired can notice my eyes are not fully natural. I took full charge of my business May 1, and have had no interruptions from ill-health."

DISCUSSION.

DR. T. H. WEISENBURG, Philadelphia, emphasized the fact that bilateral facial palsy is rare. He recently saw three such cases in Dr. Spiller's service, in the Polyclinic Hospital. An interesting report of the etiology was made by Sarbo of a case of facial diplegia, where the patient's father, mother and brother had the same disease. Sarbo inclined to the view that in these cases there was a congenital narrowing of the fallopian canal, this acting as a predisposing cause, because of the interference with the blood supply of the facial nerve; the exciting cause was probably an infection, as "taking cold."

DR. HUGH T. PATRICK, Chicago, mentioned the case of a child he saw some months ago with complete double facial paralysis. The electric examination did not show the typical reaction of degeneration, so he was inclined to think it was a tumor, but the subsequent course of the case led him to believe that it could not be a tumor, because the child has not grown worse, being, if anything, a little better. Although he thinks syphilis could be excluded from the case, he put the child on antisyphilitic treatment with no beneficial result. He has come to the belief that the case is probably a very peculiar one of myasthenia gravis. The eye muscles are not involved and the muscles of the extremities are not involved to any great extent. There is simply general weakness, lassitude, ready fatigue and this bilateral facial paralysis. He knows of no other explanation that is adequate, and he does not think that this one is quite adequate.

DR. F. E. COULTER, Omaha, Neb., recently had a unilateral case, of similar origin, occurring in a physician. The knee-jerks became absent, and there was a great deal of sweating. Both plantar reflexes were flexor in type and there was a very marked toxic state with the paralysis that accompanied the infection. When this physician had la grippe he became exhausted, with soreness and aching all over the body. He attempted, as physicians will, to do his work, and one day's driving was quite sufficient to bring on this undesirable result, Bell's paralysis. We can not yet explain why certain nerve trunks are picked out as the seat of infection by certain micro-organisms and others apparently exactly similar in structure, so far as we know, go untouched, but this is certainly the case.

DR. ALBERT E. STERNE, Indianapolis, said that he regretted that Dr. Langdon failed to test the Achilles tap in reference to the patellar reflexes; it would be interesting to know if there was any disturbance of that reflex. Dr. Sterne mentioned two cases; one of them has been referred to in a written article but the other has not been published. The first was the case of a man who had been thrown from a wagon twenty years previously in Portland, Oregon, landing on the back of the head a little to the left side. At that time he was said, erroneously, to have sustained no fracture. However, he lost the hearing in the left ear and became paralyzed on the left half of the face and left external rectus; there was loss of sensation on the right half of the body completely. Twenty years afterward, under systematic, careful treatment, this man recovered to a great degree the use of the facial muscles on the left side; his hearing remained lost and sensations on the right half of the body became almost normal twenty years after the occurrence of the lesion. The other case was unique, and Dr. Sterne has never seen anything of the kind published. A man from Seattle, Washington, had gone to Saratoga to attend a postal convention and was on his way to visit a town in Indiana, when he became stricken with symptoms exactly similar to those we see in poliomyelitis. The question arises whether in this case it was poliomyelitis, or whether it was a peripheral lesion. The man was completely and absolutely paralyzed in every portion of the body; both arms, both legs and both halves of the face completely paralyzed, and all the symptoms seemed to be those of poliomyelitis. Later there was wasting of the muscles, which were absolutely paralyzed, and reaction of degeneration, which still exists in a large part of the trunk muscles and both halves of the face, but he can use his arms somewhat, very much as in cases of regeneration following poliomyelitis. Dr. Sterne has been in doubt as to whether he should make the diagnosis of involvement of the anterior horn. Whether it was due to such involvement or to a peripheral lesion, it was the most widespread paralysis he has ever seen, either in private practice or in the hospital.

PUBLIC CARE OF THE INSANE PENDING COMMITMENT.

Some months ago, in one of the largest cities of the country, a young foreigner became suddenly insane at his boarding-house. He was hurriedly sent to the nearest police station in a patrol wagon, locked up as a prisoner for a day or so, growing constantly more maniacal, then sent in the patrol wagon again to another police station, where the city physician would find it more convenient to examine him. By the time he arrived at the second station he was in a state of intense maniacal excitement. After a struggle with half a dozen policemen, he was finally overpowered and thrust into a restraint chair, where he died within half an hour, without ever having been seen by a physician.

At about the same time in the same city a foreigner, equally obscure, became insane and shot at his roommate. He was taken at once to a police station in a patrol wagon, kept there for two days, then taken to another station more convenient for the city physician to visit, where he was kept another day, and finally was seen by the physician, who then ordered him sent to the detention hospital.

These incidents—illustrating the unmedical treatment which insane suspects frequently undergo—coming to our attention suggested an inquiry into the methods of various cities as regards public care of the insane pending commitment. Accordingly, we addressed inquiries to the mayors of a dozen leading cities as to the method by which insanity is determined in each—whether by jury trial or by medical examination, whether patients are arrested, how and where they are detained pending commitment, if patients are conveyed to the asylum by the sheriff, whether women attendants are required for women patients, and whether nurses are sent from the asylum to convey patients thither.

Accurate answers to these few questions would pretty fairly indicate the degree to which medical authority controls in a community; for we do not hesitate to say that the trial of insane patients by jury, the arrest of patients, their transportation in patrol wagons, their detention in police courts or jails, their conveyance to the asylum by the sheriff or by the police, the failure to furnish nurses from the asylum to escort patients, all indicate archaic conditions and show that in any city where they exist, the intelligent physicians have been unable to influence public affairs as they should. The answers received show all grades of treatment. In one city, our letter was handed to a member of the detective force for reply. His answer would lead one to infer that our inquiry referred to the criminal class. He states that "insane suspects are arrested, detained in the Emergency Hospital, and are held there for observation; then they are tried by a board of physicians appointed by the Superior Court to try the case, and in the event of a verdict of guilty they are committed to an insane asylum. There are women attendants appointed by the sheriff who have the custody of the female patients. The sheriff has charge of all insane cases."

It will be seen that the writer entirely ignores the first step in the commitment process, namely, the manner in which patients reach the emergency hospital. In like manner, from the very city where the incidents occurred which are mentioned at the beginning of this article, we are cheerfully assured that patients are detained in an emergency hospital awaiting inquiry as to insanity. Various cities do not undertake to dodge the question, but frankly state that "suspects" are taken to the jail or police station at first.

In cities where there are detention or emergency hospitals the general public may suppose that patients are immediately taken there. As a matter of fact, patients in these cities also are taken first to the police station or to the jail by policemen, in patrol wagons, in precisely the same manner as a common drunk. In the majority of the replies, the expressions used are those associated with the treatment of criminals—patients are "arrested," held in police stations or jails, "tried" by jury or judge or even by a board of examiners, sent to the asylum in charge of the sheriff or his deputies. All this is so commonplace that it probably does not arouse in any of us the quick sense of shame which it should. Does it shock us that in one city the coroner determines the mental state of the patients, or that in another the probate judge performs the function of the alienist?

It is superfluous to point out again the long-since recognized impropriety of entrusting the diagnosis of a disease to a jury of laymen. Slowly but surely this anachronism will disappear, though it still survives in some of our greatest centers, notably in Chicago. Our purpose is to call attention to the fact that during the first few days, so critical in cases of acute mental disorder, the treatment of the patient is distinctly nonmedical and is precisely that accorded to a felon. The public and the profession at large consider the patient as magically transferred to the asylum, which we now call a hospital, without at all realizing the terrifying experiences often undergone in the comparatively brief period between removal from home and arrival at the hospital. Consider the effect on a delicate, refined woman in the early stage of melancholia, suddenly thrust for a night into a jail or the cell of a police station. Such an experience would infallibly exacerbate the malady, and might even make all the difference between a favorable and unfavorable outcome.

In the small cities and in the country communities the treatment of patients is even more primitive than in the large towns. A patient is often brought many miles in an open wagon to the county seat, and placed in the county jail for varying periods before an examination is held. Jailers or sheriffs with the best will in the world are of course unfitted to give the care which insane patients need. We were lately told by a member of a state board of charities of a visit to a jail where many insane were received. The sheriff felt much aggrieved because he had been threatened with suit by the relatives of a patient who had been placed in the jail in a state of great excitement, and who had seriously injured his hands by beating against the bars of his cell door. When the sheriff's attention was called to good leather muff and wristers hanging in the office, whose use would have prevented the whole trouble, he said contemptuously: "O! them things; they've been there since before I came, but I've never touched 'em."

It is a relief to turn to instances of excellent management in some of the cities from which we have replies. Three cities seem to have nothing of the police method in their manner of dealing with the insane. These are New York, St. Louis and Baltimore. In the city of New York patients may be detained for examination as to their mental condition in but one place, the pavilion at Bellevue Hospital. Three examiners in lunacy are employed by the city of New York. They are physicians, holding their positions under the civil-service law. These examiners are stationed at Bellevue Hospital, and the patients are under their care pending commitment. Following an order for commitment, the state hospital authorities are notified, and they send trained nurses to accompany patients from the pavilion to the institution. Women patients are always accompanied by women nurses.

In Baltimore the procedure is very simple. The hospitals being in the suburbs of the city, the process of commitment need occupy but a few hours. Two physicians visit the patient in his home, and on their recommendation the board of charities makes out the commitment papers and notifies the hospital to send its ambulance, and, if necessary, a female attendant to convey the patient to the institution.

St Louis uses the observation ward at the City Hospital for the detention of patients previous to examination. On the certificate of two physicians, patients may be committed to the asylum. They are conveyed in a city ambulance, and attendants are sent from the hospital to accompany them. Doubtless there are other towns where the treatment of the insane has been divorced from the care of criminals. At any rate, the instances we have cited are cheering. We commend to county and district medical and state societies an inquiry into the actual conditions surrounding the care of the insane pending commitment in their respective communities.

THE PATHOLOGY OF ICTERUS.

In a condition like icterus, which is a symptom of many different diseases, there is always a desire to find a common factor underlying all cases. In the early days of pathology it was assumed that in all instances this common underlying factor was a mechanical obstruction of some sort, but it very soon became evident that in many cases no such mechanical obstruction could be found. In such cases the signs of biliary stasis in the liver itself, dilatation and overfilling of the bile ducts, stasis of bile in the interlobular bile passages and deposition of bile pigment in the liver cells, are entirely lacking. Inability to account for such cases on mechanical grounds led to the conception of hematogenous as opposed to hepatogenous icterus. It was thought that bile could be manufactured not only in the liver, but also in the blood. The latter form of bile formation was thought to occur in toxic and infectious conditions in which a large number of blood corpuscles were broken up in the circulation. As a result of this conception all cases of icterus which could not be classed as obstructive were ranged under hematogenous icterus, or as Naunyn and Minkowski called it, icterus from polycholia. Later it was shown that something more than excessive blood destruction was needed to account for such cases when the liver was acting normally, and in recent years many have held that the second necessary factor was a disturbance in the function of the liver cells themselves. This change in the liver cells has been compared to the disturbance in the kidney cells which produces albuminuria. This hypothesis explained especially well the icterus of infections or intoxications, and that of circulatory or nervous disturbances, because in just such conditions it was easy to imagine that the secretory powers of the liver cells might be affected. Some writers went so far at this time as to almost deny to mechanical factors any importance at all.

The recent work of Eppinger, which was based on painstaking histologic examinations and a method which rendered the walls of the bile capillaries easily visible, has led back once more to a mechanical theory of icterus. He found in various forms of icterus a dilatation of the bile capillaries with elongation, sinuosity, varicose swellings and even rupture of the walls. As a result, the bile was able to gain entrance into the perivascular lymph spaces. The obstruction, though mechanical, was not in the larger bile passages, but in the capillaries, which were either compressed by new-formed connective tissue or blocked by bile thrombi. These observations have been confirmed in the main by Abramow and Samoilowicz. Recently Winckelmann,[1] working at

---

[1] Zeitschrift für klin. Medicin, vol. lv.

Minkowski's suggestion, has gone over the work afresh. The point in which Eppinger's conception differs most radically from the preceding theories of icterus is in the rôle played by the lymph spaces surrounding the bile capillaries. Doubt has been cast on the existence of such spaces, and even Eppinger himself does not describe them as definite vessels, but merely as spaces between the walls of the bile capillaries and the liver cells. According to Minkowski, there is little doubt that such spaces exist. Eppinger seems to think that in icterus the bile must reach the blood by means of the lymph channels, and there is some support to this view in the old observations of Harley and von Frey, who showed that if the thoracic duct be ligated at the same time as the ductus communis choledochus no icterus would occur. This, of course, necessitates the view that while the blood capillaries of the liver are permeable for some substances they are not permeable for bile, an idea which is by no means unthinkable in the light of our present knowledge of cell specificity. Another point in which Eppinger's conception differs from preceding ones is the recognition of the bile-stained plugs in the capillaries as bile thrombi. These are not made up of pure bile, but are bile-stained concrements which form when, as a result of disturbances in the liver cells, abnormal substances are excreted with the bile. These bodies can, perhaps, more reasonably be compared to the urinary casts than to thrombi.

While this work of Eppinger explains the pathology of many cases of icterus, Minkowski points out that all cases examined since its publication have not shown these lesions. This is especially true of cases of infectious icterus. In just such cases it has been shown that the bile is often abnormal, and may contain albumin. Such cases are probably due primarily to the liver cell changes, though the bile thrombi and mechanical stasis may occur as secondary phenomena. Minkowski thinks that though the work of Eppinger has greatly extended our knowledge of the pathology of icterus we must still recognize two forms—the true obstructive icterus, in which mechanical obstruction plays the main part, and the toxic, cyanotic and nervous forms, in which the disturbance in the function of the liver cells is the important factor.

TRUTH AND POETRY CONCERNING URIC ACID.

II.

The history of uric acid dates from a year easily remembered by Americans. In 1776 the substance was discovered by Karl W. Scheele as the constituent of a concrement, and in the same year T. Bergman found it in a stone from the bladder. Soon after it was recognized as a normal ingredient of the urine; it was fated to become the object of a long series of studies. Pure chemists busied themselves with it for a time, Fourcroy (1793) finding urea among its decomposition products, and Wöhler and Liebig (1838), showing that it is closely related to allantoin, urea and alloxan. The majority of the earlier studies on uric acid were undertaken by medical men, and one of the most interesting features of medical research during the past hundred years is the patient but tortuous course followed by those who had as their object the determining of the mode of formation of uric acid in the body. At times the pursuit seemed to be utterly futile, so ignorant were those engaged in it of the direction it should take; more than once it was necessary, to use a sportsman's expression, to "hunt change," to take a fresh scent as it were, and to seek in an entirely new quarter.

The relationship of uric acid to urea naturally suggested a similar origin for the two substances, and the earliest theories took it for granted that uric acid, like urea, is a product of albumin metabolism. Since uric acid yields urea as one of its oxidation products, two hypotheses seemed plausible—either all albumin on oxidation to urea passes, at some time or another, through a uric-acid stage, or albumin is normally oxidized directly to urea, but under certain pathologic conditions to uric acid instead. In case either hypothesis were true, a fault of oxidation would account for the appearance of increased amounts of uric acid.

Thus Lehmann, in his "Physiological Chemistry," published in 1853, advanced the first hypothesis, assuming that uric acid stands a rung higher on the ladder of descending albumin metabolism than does urea. This view was accepted by many, and the idea became prevalent that an increased excretion of uric acid must be due to disturbances of the circulation or respiration leading to interference with the normal oxidizing processes of the body. Feeding experiments (Neubauer, 1856; Meissner, 1868; Weintraud, 1896, and Spiegelberg, 1898) demonstrated that uric acid in dogs or human beings is given off largely as urea in the urine, one study showing that not more than 5 per cent. of the uric acid fed reappears unchanged in the urine. Haig (1894) asserted that, feeding small amounts of uric acid to healthy men, he could demonstrate prompt and complete excretion as such in the urine, but he is alone in this as in so many observations which contradict the work of more accurate investigators. Of course, the fact that uric acid, like other nitrogenous substances, burns in the body to urea, is no proof that all urea goes through a uric-acid forestage, and investigators were soon to learn this.

The first hypothesis received telling support from Bartels[1] (1866), who sought evidence in its favor in clinical experience, or rather, who looked for facts that were not out of harmony with the hypothesis. He laid emphasis on the "relative" amount of oxygen available; if there were "relative" insufficiency of oxygen, uric acid, he thought, instead of urea is formed. Thus in certain fevers, like that in pneumonia or those accompanying circulatory disturbances, there might be increase in uric-acid formation owing to "relatively" insufficient respiration. Excess of uric acid in leukemic urine he cited as evidence of his view. Virchow had called attention to this increase in uric acid in leukemia as early as 1847, and regarded it as due to imperfect oxidation.

---

[1] Bartels: Untersuchungen über die Ursache einer gesteigerten Ausscheidung der Harnsäure in Krankheiten. Deutsches Arch f. klin. Med., vol. 1, 1866, p. 13.

In this connection it is of great interest to note that Scherer,[2] as long ago as 1851, had found hypoxanthin in the spleen and in the blood in leukemia, and had put forward the theory that leukemia is due to a sort of hypersecretion of the spleen. Five years later he found both hypoxanthin and uric acid in the blood in leukemia. The chemical relations of hypoxanthin and uric acid were beginning to be known, and a hypothesis that the spleen is the source of uric acid gained credence for a time, Ranke[3] marshaling as arguments in its favor, (1) the increase of uric-acid excretion with accompanying splenic swelling during digestion; (2) the increase of uric acid in leukemia; (3) the presence of uric acid in the splenic juice; and (4) the action of quinin which reduces the size of the spleen and diminishes uric-acid excretion. The possibility of an origin of uric acid from hypoxanthin—excessively interesting considering our present knowledge of the purin bases—seemed to threaten the view that it is derived from albumin, until some one suggested that hypoxanthin might come also from albumin and be simply a still earlier forestage of urea. Moreover, Bartels' authority was so great that his conception was the dominant one in the minds of medical men for a long time.

Telling blows against Bartels' view were struck later when it began to be shown (1) that conditions which diminish oxidation or interfere with respiration are not necessarily associated with increased uric-acid excretion; and (2) that in leukemia, where uric-acid excretion is sometimes increased, there is no evidence that the oxidizing processes are diminished. Senator (1868) constricted the thorax of dogs and rabbits, and got increased uric-acid excretion in only two out of many cases; Naunyn and Ries (1869) did not find the uric-acid excretion increased in anemia produced experimentally; Pettenkoffer and Voit (1869) showed that nitrogenous and carbon-dioxid equilibrium are maintained in leukemia in spite of uric-acid increase, and finally, in 1891, Kraus and Chwostek, and in 1893, Bohland and Geppert proved that there is absolutely no decrease in the oxygen-intake, nor any decrease in the output of carbon dioxid, in cases of leukemia.

It can be seen, therefore, how it came about that some of the oldest conceptions regarding the formation of uric acid had to be given up. These old views have had a sort of recrudescence, however, from time to time, as will be pointed out further on, when we come to deal with the ideas which supplanted them.

LOEFFLER'S NEW METHOD OF PRODUCING ANTIBODIES.

It is a familiar fact that the injection into the animal body of gradually increasing quantities of many substances gives rise to the production of specific antibodies. Among the most carefully studied substances of this class may be mentioned bacterial toxins, living and dead bacteria, red blood corpuscles, blood serum, organ cells, etc. By heating these substances, or by treatment with various chemicals, they are easily deprived of the power of calling forth antibodies. It often is desirable, however, to kill the bacteria that are used in the process of immunization before they are injected, because some living organisms, as, for instance, the tubercle bacilli, are not well borne by any of the animals that are suited for the production of antiserums. In other instances it may be necessary to sterilize the substance before it is used, because of the great difficulty of obtaining it without accidental contamination.

In these cases it has been difficult to find a convenient and reliable method of killing the bacteria without, at the same time, depriving them, or the substance which is being sterilized, of the power of calling forth antibodies. These difficulties were partly overcome by grinding up the bacteria to such a fine state that the mass no longer contained organisms capable of growth, or by sterilizing the accidentally contaminated substance with chloroform. These methods of sterilization are not perfectly reliable, and it not infrequently happened that the animal under treatment died in consequence of an injection of an imperfectly sterilized substance.

We know that enzymes, when perfectly dry, may be heated to a high temperature without being deprived of their specific properties. This fact led Loeffler[1] to attempt to produce antibodies with bacteria that had been dried and killed by heating to 150 C. for one-half hour. He not only used bacteria that were thus treated, but also blood serum, organ cells and tumor cells, and his labors seem to have been crowned with success. He dried chicken serum at a low temperature and heated the dry residue to 150 C. for one-half an hour. The residue was suspended in salt solution, and several doses were injected into a rabbit. The serum of this rabbit formed a heavy precipitate with normal chicken serum. Other heated sera were injected into various animals, and all gave rise to the formation of a specific precipitin. Loeffler dried and heated bacteria to 150 C. for one-half an hour, and immunized animals by injecting them with suspensions of the heated organisms. In this way he produced agglutinating sera for *B. typhosus*, *B. coli communis*, *B. choleræ*, the bacillus of hog cholera and the tubercle bacillus. He also obtained a serum with high bacteriolytic powers for the bacillus of cholera. Carcinoma cells were dried and heated, and suspensions of the dry powdered cells were injected into a mule. The serum of this mule gave a precipitate with a colloidal solution of carcinoma tissue, and also with such a solution of lymphoid tissue. A woman suffering with carcinoma of the breast was treated with this serum and also with a solution of the heated carcinoma cells. There was local reaction and apparent general improvement, but no arrest of the growth of the tumor.

---

[3] Ranke, H.: Beobachtungen und Versuche über die Ausscheidung der Harnsäure beim Menschen, München, 1858.

[1] Deutsch. med. Woch., Dec. 22, 1904.

Loeffler claims that this method of desiccation, heating and pulverizing will allow the material to be kept for indefinite periods, and will eliminate all danger for those handling it. Just how much can be expected from this discovery can hardly be conjectured at this time, but it seems that it may find wide application in the production of various antiserums.

WARNING AGAINST PANAMA LABOR.

The danger of misconception of the conditions in Panama[1] has led the American Federation of Labor to send circulars over the country calling attention to the real status of affairs at the Panama Isthmus. The federation declares that it is not true that the work will be easy and the wages above the normal, and urges especially that no one should go to the canal zone unless he has a position and knows under what conditions he is to labor. The warning is a timely one. The glamor naturally attendant on this great government enterprise is heightened by the illustrated articles in the papers and magazines, in spite of the frequent mention of the diseases that have been so great a factor in the mortality rate. Many who go to Panama with a little knowledge of conditions there, are liable to desire a speedy return when their knowledge is increased. The great enterprise will not lack for workers, and it will only be hindered by illy prepared adventure-seekers.

THE GROWING IMPORTANCE OF PHYSICS IN MEDICINE.

Coincident with the rapid application of chemical methods to the study of medical problems, there has been a growth of interest in more purely physical phenomena, and especially in the phenomena of that ever-widening domain which we now know as physical chemistry. The publications of Van t'Hoff, Arrhenius and Ostwald have stimulated a whole series of medical and biologic researches, like those of Pauli and Loeb, on the one hand, and those of Koranyi, Hamburger and Höber, on the other. Zikel. in 1902, published a volume on what he calls "Clinical Osmology," which deals with the osmotic states of the body fluids in health and disease. It is surprising how rapidly clinical concepts are being widened as a result of the application of these newer ideas of physical chemistry. Only a beginning has, of course, as yet been made, but the work which has been done is full of promise for the future. On page 184 of this issue Stern discusses the relations of the modern science of osmology to pharmacodynamics. In the latter field also, as will be seen by a perusal of his article, he believes that purely physical influences play an extremely important rôle. Osmotherapy is likely, he thinks, to be one of the coming developments in practical medicine.

NATIONAL INCORPORATION OF THE AMERICAN MEDICAL ASSOCIATION.

On January 9 Congressman Dwight of New York introduced a bill[1] for the national incorporation of the American Medical Association by special act of Congress. This is of special interest to the members of the American Medical Association, and, in fact, to the members of the medical profession of the country. Obtaining recognition by Congress will not only add dignity to the body which represents the medical profession of the United States, but will give it a power and an influence for good which it would not otherwise have. We hope that every physician who has at heart the betterment of sanitary affairs of our country, and the various matters in which the medical profession is interested, will use his influence where it will do the most good. The bill was referred to the Committee on the Judiciary, and at the present time the matter is wholly in its hands. Consequently, all legitimate efforts should be made to convince its members of the value and importance of the measure. The members of the Committee on the Judiciary are: John J. Jenkins, Wisconsin (chairman); R. W. Parker, New Jersey; D. S. Alexander, New York; Vespasian Warner, Illinois; Charles E. Littlefield, Maine; Lot Thomas, Iowa; Samuel L. Powers, Massachusetts; Robert M. Nevin, Ohio; Henry W. Palmer, Pennsylvania; George A. Pearre, Maryland; J. N. Gillett, California; David A. De Armond, Missouri; David K. Smith, Kentucky; Henry D. Clayton, Alabama; Robert L. Henry, Texas; J. S. Little, Arkansas, and William G. Brantley, Georgia.

LONGEVITY OF JEWS.

It is claimed that of all classes of New York City's population, the Jews are the longest lived. Considering the manner in which the majority of the Jewish population of our great cities live, this is a remarkable showing, if true. The poorer Jews, as a rule, are rigid followers of the Mosaic law, and this would indicate to some extent the excellence of the sanitary provisions of that ancient code. Insurance men, however, it is alleged, while recognizing the temperance of the Jews as a factor, are inclined to think that this longevity is a result of natural selection, the weaker elements of the Jewish race having been gradually eliminated during centuries of persecution. There is still another possible factor to be considered. For centuries the Jews have become acclimatized, so to speak, to city life, and therefore may represent the class most resistant to such environment. There are evidences, however, that modern civilization is telling through its stress and strain on the vitality of the Hebrew race. Paresis, which was formerly said to be rare among them, was found by Beadles to be particularly frequent among the London Jews. It would be a matter of much interest if a thorough study were made of this racial peculiarity of the Jews with special reference to its causal factors, and in comparison with special classes of the non-Jewish population and of wider scope than any such study yet made, both as to time and territory. It may take years, however, to reach positive conclusions, and in the meantime evolutionary changes may be taking place that will materially alter the conditions. A hundred years from now, and in even less time in some countries, the present distinctive Jewish element may have become entirely absorbed in the general population.

---

[1] Announcement of the Civil Service Commission concerning conditions of service in Panama was given in The Journal, Dec. 17, 1904, p. 1881.

[1] The bill is printed in the General News columns, page 227.

TOTAL ABSTAINERS AND LIFE INSURANCE.

Jews are not the only long-lived class, according to the New York actuaries. While the well-to-do Hebrew who takes life insurance is said to be 15 per cent. better risk than the average, total abstainers from alcoholic drinks make a still better showing—from 20 to 50 per cent. over the moderate drinkers, including the Jews. The average Jew is probably not a total abstainer, and it would be of interest, if it were possible, to study out by comparison with the teetotalers the reason for the advantage of the latter. From 5 to 35 per cent. is therefore the percentage that can be credited in favor of abstinence. Of course, there are many elements that enter into the solution of the question beside the mere abstinence from alcohol, such as the probable relatively lesser frequency of accidents and exposure. etc. It seems pretty clear, however, that the advantage is with the total abstainers, and that even moderate drinking detracts from the tendency to longevity.

THE NOBEL AWARDS.

It has been a matter of some unfavorable comment that while nearly all of the European countries. except Italy and Austria, have been represented in the awards of the Nobel prizes, thus far America has been left out. It has been suggested that many of our inventors and investigators who have achieved special eminence have worked largely from practical and money-making motives, and have not been inspired sufficiently by the true scientific spirit. While this is true of a number of our great men, it has no reference whatever to a large number who ought to be mentioned as candidates for the Nobel prizes. The public here is inclined to think more of the practical side, to magnify the work of a Morse, rather than that of a Henry, on which it was based. The names of Edison, Tesla, Bell and others are everywhere familiar, while the names of those who established the principles on which the inventions depend are hardly known. In connection with this, it is of interest to note what is perhaps the principal reason—the real reason—why American workers have not been selected for the prizes. Under the conditions of the bequest of Nobel, personal applications are not received; the names of candidates must be presented for consideration by some recognized learned or scientific association or university faculty, thus relieving the awarding committee of the preliminary labor of searching out those who may be considered worthy by their compatriots or associates. When we look over the field of medicine, which is one of those in which the prizes are awarded, it does seem as if some disinterested work and some names worthy of consideration might be suggested to the awarding bodies. There has been no more fruitful or important work in the past few years than the discovery of the cause and means of prevention of yellow fever, and some survivors of that investigation have never received full recognition of their services except among their scientific brethren. The names of others whose work deserves this recognition will at once occur to scientific bodies. The American Medical Association and other organizations should see to it that their lack of activity on the subject no longer leaves an excuse for the committee to ignore America.

THE EFFICIENT JAPANESE ARMY MEDICAL DEPARTMENT.

World's Work for January contains an admirable note on "A New Epoch in Army Mortality," having for its text the effective work of the Japanese army medical corps. The Japanese medical officers are rightly praised for their work in superintending the personal hygiene of the soldier, as well as in superintending the sanitation of trench and camp. Comparing their work with that of our own army medical corps, our contemporary finds the difference in efficiency to lie "in organization and in the obedience of the men." This is a half truth. As we all know, the chief reason for the disgraceful sanitary regulations of the American Army in the Spanish war was the absence of authority in the hands of the medical officers. The Japanese medical officer can order the troops to obey certain hygienic rules. Our Army organization permits the surgeon merely to suggest. When, as at scourged Camp Chickamauga, a line officer, ignorant and self-sufficient, is in command, he can sneer at the medical recommendations which in his wisdom (?) he overrules, and may likewise be too callous to appreciate the disgrace and the personal responsibility for hundreds of needless deaths from preventable fever. The Japanese line officers may be better trained and may have a wide intelligence, but over all stands the fact that Japan provides her army medical corps with a sufficient number of members and with authority to execute those necessary precautions that are within the common knowledge of the medical profession of the world. Every American should feel chagrined that a yellow race should conduct a war with more scientific enlightenment and with greater care for the health of its soldiers than we ourselves are prepared to do. Congress has put our country far to the rear in one of the foremost characteristics of modern civilization. No fear of our soldiers not "obeying" if but an educated man is given command. No soldier is better, and whenever our authorities give the medical corps its due, it will show that the American medical officer, too, can save lives. To the closing question of our contemporary there is but one answer: the "general incredulity born of ignorance" is responsible for American disregard of medical advice. If our esteemed contemporary will for a time follow the medical press, it will readily discover that the medical profession is not to blame for public inattention to its endeavors to prolong life and to promote well-being.

Medical News.

ARKANSAS.

Asylum Report.—The biennial report of the superintendent of the Arkansas State Lunatic Asylum, Little Rock, shows that 3,631 have been admitted into the institution since it was established, and 236 in the last two years.

Smallpox in Pulaski County.—According to a statement issued by the county physician, there are about thirty-five cases of smallpox in the county, outside of the towns of Little Rock and Argenta. These cases were mostly among the negro population in the vicinity of Jacksonville and McAlmont.

CALIFORNIA.

Hospital Open.—Good Samaritan Hospital, Los Angeles, was formally reopened December 29 after improvements and enlargements had been made costing $1,000,000. It now can accommodate 100 patients.

Personal.—Dr. Hubert N. Rowell, Berkeley, has been appointed attending physician at the California State Home for the Adult Blind.——Dr. Jules A. Simion has been made a member of the San Francisco Board of Health, vice Dr. J. Coplin Stinson, resigned.——Dr. Luther M. Powers has been appointed health officer of Los Angeles, Dr. Harris Garcelon, assistant, and Dr. Sumner J. Quint, police surgeon.——Dr. Ferdinand Stabel, Redding, has been appointed physician and health officer of Shasta County.——Dr. John L. White has been made superintendent of the Sacramento County Hospital.

COLORADO.

Fire in Hospital.—Fire in the fifth floor of St. Mary's Hospital, Pueblo, nearly caused $25,000 damage and necessitated the removal of most of the patients, fortunately without casualty.

Sanitarium for La Junta.—The La Junta Sanitarium Company has been incorporated with a capital stock of $25,000, by Drs. James F. Kearns, Edward W. Ragsdale, Frank Finney, Jessie E. B. Stubbs, E. Gard Edwards, Benjamin F. Haskins and others. A hospital will be built, and a cottage sanitarium for tuberculosis will also be erected.

Self-Advertisement.—About a year ago the Otero County Medical Society requested the newspapers of the county to refrain from mentioning in any way the name of any member of the society in news items relative to illness or accident. In La Junta the request has been complied with except in two instances, and the editor has promised not again to offend.

CONNECTICUT.

Personal.—Dr. Joseph E. Root, Hartford, surgeon of the First Company, Governor's Horse Guard. has resigned.——Dr. Charles I. Page, Litchfield, and William J. Ford, Washington, have been appointed by the adjutant general post surgeons for Litchfield County.

Bequests.—An unknown benefactor has given $15,000 to Grace Hospital, New Haven, to be used for enlargement of the nurses' dormitory.——By the will of Miss Maria Terry, who died recently in Venice, Hartford Hospital will receive nearly $500,000.——Mrs. Israel Matson Lyme has bequeathed $5,000 for the use of Memorial Hospital, New Haven.

December Mortality.—During December 1,258 deaths were reported, equivalent to an annual death rate of 15.5 per 1,000. This was 96 more than in November, 89 less than in December, 1903, and 40 less than the December average for the preceding five years. Diseases of the nervous system caused 161 deaths; pneumonia, 153; heart disease, 135; consumption, 102; violence, 64; bronchitis, 33; and la grippe and diphtheria, each 26.

GEORGIA.

Donations for Hospital.—About $11,000 has been raised for the Wesleyan Memorial Hospital, Atlanta, and a prominent Methodist has, it is understood, offered to give $12.500 provided the Methodists of Atlanta would contribute a like sum.

Personal.—Drs. F. M. Ridley, La Grange, and W. Darracott Travis, Covington, have been appointed members of the Board of Medical Examiners for three years, beginning January 7.——Dr. Bernard Wolff has been elected a member of the Atlanta Board of Health.

Kills Vaccinator.—Boss Garrett of Sandersville shot and killed Special Officer Gideon Mathews, December 23, while resisting arrest for refusing to submit to compulsory vaccination. Garrett was shot through the thigh while attempting to escape and is not expected to live.

Society Election.—At the annual meeting of the Chatham County Medical Society of Savannah, January 4, the following officers were elected: Dr. George R. White, president; Drs. Ralph M. Thompson and John L. Farmer, vice-presidents; Dr. J. L. Jackson, recording secretary; Dr. A. L. R. Avant, treasurer; Dr. J. Lawton Hiers, corresponding secretary; Dr. Gustaf H. Johnson, librarian, and Drs. Marion X. Corbin, John W. Daniel and Alpheus B. Simmons, censors.

ILLINOIS.

Bogus Doctor Fined.—"Dr." Black, Rockford, charged with practicing medicine without a license, was fined $100 and costs, January 6. Black claimed that he had a diploma, but that it was in the hands of a saloonkeeper in Janesville, Wis.

Personal.—Dr. James W. Pettit, Ottawa, was thrown from his buggy January 1 while making a late call and sustained a compound fracture of the left arm above the elbow.——Dr. Benjamin L. Euans, Watseka, returned from Europe January 7.——Dr. Denslow Lewis, Chicago, is suffering from typhoid fever.

Hospital Elects Officers.—At the annual meeting of the officers and trustees of Brokaw Hospital, Bloomington, Dr. James B. Taylor was elected president; Dr. J. Whitefield Smith, vice-president; Dr. John W. Fulwiler, secretary and treasurer; Dr. Ernest S. Reedy, medical representative, and Drs. John H. Fenelon, Asa S. Fox and Covey were recommended as members of the staff.

Chicago.

Hospital to Expand.—The Passavant Memorial Hospital has acquired from O. B. Green, property adjacent to its present building, and will erect thereon a dormitory for nurses.

The Death List.—The total deaths reported, 542, were the same in the aggregate as for last week, but there were some curious changes in the individual causes of death. The following among the important show increases: Acute intestinal diseases, 7; apoplexy, 12; consumption, 11; cancer, 5; convulsions, 10; influenza, 12; suicide, 7, and typhoid fever, 3. Important causes showing decreases were: Diphtheria, 3; heart disease, 15; nervous diseases, 9; pneumonia, 27; whooping cough, 3, and measles and scarlet fever, 1 each.

The Dangers of Influenza.—The Health Department in the current issue of its Bulletin, warns strenuously against influenza, and says:

> Influenza is more prevalent and more fatal in Chicago this winter than at any time since the epidemic year 1891; twenty more deaths from this cause were reported during the week. In 1891 influenza was the chief agent in increasing the death rate more than one-fifth over that of 1890 and numbers of the survivors have never since regained their former condition of mental and physical health. This added terror of the disease makes it all the more important that nothing should be neglected which may tend to its restriction, and to this end the commissioner again points out that influenza or the "grip" is a germ disease, and therefore contagious. Hence the obvious thing to do is to follow the advice of the authorities: Keep out of the way of contagion.

The Hospital Staff.—The long-awaited announcement of the appointments to the attending staff of the Cook County Hospital has been made. The regular staff is as follows: Medicine—Drs. Robert H. Babcock, Maurice L. Goodkind, Winfield S. Harpole, James B. Herrick, Charles L. Mix, Joseph L. Miller, Robert B. Preble, Bertram W. Sippy, Samuel R. Slaymaker, Frederick Tice, Camillo Volini and Edward F. Wells. Obstetrics—Drs. Rudolph W. Holmes, Henry F. Lewis, Charles B. Reed and Rachelle Yarros. Children and Contagious Diseases—Drs. William L. Baum, Frank B. Earle, Isaac A. Abt, Frank S. Churchill, Frank X. Walls and George H. Weaver. Nervous and Mental Diseases—Drs. Sidney Kuh, Julius Grinker, L. Harrison Mettler and Harold N. Moyer. Surgery—Drs. E. Wyllys Andrews, Frederic A. Besley, Albert I. Bouffleur, Thomas A. Davis, Charles Davison, William E. Schroeder, C. W. Haywood, Aime P. Heineck, Orville W. Mackellar, B. Brindley Eads, Daniel N. Eisendrath, Malcolm L. Harris, A. E. Halstead, William Hessert, Frederick S. Hartman and Charles E. Humiston. Ophthalmology—Drs. William E. Gamble and Brown Pusey. Ear, Nose and Throat—Drs. Frank Allport and G. Paull Marquis. Skin and Venereal Diseases—Drs. L. Blake Baldwin and William A. Pusey. Pathology—Drs. William A. Evans and Edwin R. Le Count. Orthopedic Surgery—Dr. John L. Porter; and X-Ray, Dr. Edward A. Fischkin. Dr. William L. Baum was elected president of the staff.

INDIANA.

St. Mary's Hospital, Evansville, has recently been enlarged so that it can now accommodate 125 patients. An operating pavilion has also been added and a pathologic laboratory installed. At the annual meeting the following attending staff was appointed: Surgery—Drs. Pitt Y. McCoy, Charles P. Bacon and George W. Varner. Medicine—Drs. Joseph N. Jerome, Sidney J. Eichel, and Clarence Kelsay. Eye and Ear—Dr. Louis D. Brose; and Electrotherapeutics—Dr. William R. Davidson.

Suit Against Physicians Dismissed.—In the $5.000 damage suit brought against Drs. Frederick C. Eckelman and Metius M. Eckelman, Elkhart, for alleged malpractice in the treatment of a broken leg, the case against Dr. Frederick C. Eckelman was dismissed before the trial began on the ground that he was not in partnership with his son and had had nothing whatever to do with the treatment of the plaintiff; and after a three days' trial the jury returned a verdict for the remaining defendant, Dr. Metius M. Eckelman, completely exonerating him.

November Sickness and Death.—The most prevalent malady was bronchitis, which stood third in the preceding month. Typhoid fever dropped from second to fourth place. The order of prevalence was as follows: Bronchitis, tonsillitis, rheumatism, typhoid fever, scarlet fever, influenza, pneumonia, diarrhea, smallpox, pleuritis, diphtheria, inflammation of bowels, whooping cough, puerperal fever, measles, cerebrospinal meningitis. Smallpox was reported in 37 counties, with 335 cases and 12 deaths. Tuberculosis caused 337 deaths, 31 being non-pulmonary; females, 201; males, 136. Of the females 68 were married, between the ages of 18 and 40, and left 140 orphans under 12 years of age. Of the males 19 were married, of the same age period as above, and left 38 orphans. The total number of orphans caused by this disease in this month was 178. More than 300 homes were invaded. Of the 92 counties, 61 reported typhoid fever present, and probably it existed in every one of them. In the month 403 cases were reported, with 141 deaths. The disease was epidemic in Marion, Parke, Shelby, Vanderburg, Wabash, Clark, DeKalb and Grant counties. Pneumonia deaths numbered 229. The total number of deaths reported was 2.566, equivalent to an annual rate of 11.7 per 1.000. In the same month last year there were 2.516 deaths, a rate of 11.3 per 1,000.

MARYLAND.

Insane Hospital Report.—The one hundred and seventh annual report of the Maryland Hospital for the Insane shows the total number of patients under care during the year as 636. The average number of patients under treatment was the greatest in its history and its utmost capacity is reached.

New Staff Members.—The following have been added to the Cambridge Hospital staff: Orthopedic surgery, Dr. William S. Baer, Baltimore; surgery, Drs. Isaac R. Trimble, Baltimore, and William H. Noble, Philadelphia; obstetrics, Dr. Lewis M. Allen, Baltimore. A number of physicians from the Eastern Shore were made consultants.

Consumptive Hospital.—Dr. Henry Barton Jacobs has been re-elected president of the Hospital for Consumptives. The receipts for the year were $7.649, and expenditures $8.145, but of the deficit all has been raised except $500. There were 100 patients treated, 17 of whom remained only two weeks; 6 were discharged apparently cured; 16 died; 26 showed improvement. The average cost per patient for the year was $81.45.

Baltimore.

A Good Record.—There has been no case of smallpox in this city since July 1.

Coroners Busy.—Between May 1 and Dec. 31, 1904, the nine coroners of Baltimore investigated 830 deaths and held inquests in 65 cases, a total of 895.

The Herter Lectures.—Dr. Hans H. Meyer, professor of pharmacology in the University of Vienna, has accepted an invitation to deliver the second course of Herter lectures at the Johns Hopkins Medical School next October.

Disinfection of Library Books.—The Enoch Pratt Free Library has not installed any apparatus for the fumigation of books, as the Health Department provides for it. The department sends lists two or three times a week showing houses in which there are patients suffering from contagious diseases. These are kept for reference and when books are returned from any of them the assistants refuse to accept them unless either a physician's certificate is shown or a Health Department certificate that the volume has been fumigated. There has been no case of infectious disease among the employes in twenty years.

Hospital Reports.—At the Hebrew Hospital the receipts for the year were $20,020, leaving a deficit of $2,243. During the year 229 patients were admitted, of whom 101 were discharged cured, 90 improved, 10 unimproved and 10 died. In the dispensary 6,908 patients were treated and 7,532 prescriptions compounded. Improvements will be made in the operating room at a cost of $3,000. Dr. Samuel L. Frank was re-elected president of the association.——At the Presbyterian Eye, Ear and Throat Hospital last year 11,000 patients were treated. The visits to the out-patient department averaged 102 per day, and operations were performed as follows: Eye, 1,782; ear, 168; throat, 770.

Personal.—Dr. Howard A. Kelly has returned from a two weeks' hunting trip in the wilds of Florida.——Dr. George Y. Everhart, speaker of the last House of Delegates, has been appointed clerk in the state treasurer's office.——At the one hundred and fourth annual meeting of the managers of the Baltimore General Dispensary, held January 12, Drs. Haughton A. Baxley, Edward E. Mackenzie and Leonard E. Beach were elected attending physicians.——Dr. Curtis R. Burnam, resident gynecologist at the Johns Hopkins Hospital, has resigned and will go to St. Paul, Minn., to practice. Dr. G. R. Holden succeeds him.——Dr. Frank W. German fell on the ice January 7 and sustained a fracture of the left fibula.——Dr. William H. Baltzell is spending the winter in Egypt.

MICHIGAN.

Scarlet Fever Epidemic.—In East Tawas there are 18 cases and the disease is spreading rapidly. The public schools have been closed. One death has occurred.

Declines Appointment.—Dr. Thomas B. Cooley, Ann Arbor, who was selected by the Washtenaw County board of supervisors as consulting physician in cases of contagious disease, with a maximum fee of $15 and expenses for each case, has declined the appointment on account of the fixed fee and expenses.

The Most Dangerous Communicable Diseases.—Meningitis was reported during December at 5 places, whooping cough at 19 places, measles at 51 places, pneumonia at 82 places, diphtheria at 91 places, smallpox at 101 places, typhoid fever at 105 places, scarlet fever at 126 places, and consumption at 241 places. Meningitis was reported present at 1 place less, whooping cough at 1 place more, measles at 16 places more, pneumonia at 23 places more, diphtheria at 4 places more, smallpox at 2 places more, typhoid fever at 56 places less, scarlet fever at 21 places more and consumption at 6 places less, in the month of December, 1904, when compared with the preceding month.

Comparative Prevalence of Disease.—For December, 1904, compared with the average for December in the last 10 years, smallpox, dysentery and inflammation of brain were more than usually prevalent; and pleuritis, pneumonia, intermittent fever, erysipelas, diphtheria, whooping cough, remittent fever, cholera morbus, puerperal fever and meningitis were less than usually prevalent. In every month of 1904 six of the diseases which were less prevalent than usual in December—pneumonia, intermittent fever, erysipelas, whooping cough, remittent fever and cholera morbus—caused considerably less sickness than the average of corresponding months in preceding years. Also, excepting July and August, this was true of pleuritis. Ten diseases caused less sickness in December, 1904, than the average for the ten preceding Decembers.

Mortality of Michigan During December, 1904.—The total number of deaths reported to the department of state for the month of December was 2,782, corresponding to a death rate of 13.0 per 1.000 population. This rate is higher than that for the preceding month, which was 11.6 per 1,000, but lower than the rate for December, 1903, which was 14.1 per 1,000. By ages there were 519 deaths of infants under 1 year of age, 133 deaths of children aged 1 to 4 years, and 922 deaths of persons aged 65 years and over. A considerable increase is shown for the rate of mortality of infants and the aged as compared with November. Important causes of death were as follows: Tuberculosis of lungs, 176: other forms of tuberculosis, 26; typhoid fever, 51; diphtheria and croup, 50; scarlet fever, 12; measles, 5; whooping cough, 10; pneumonia, 234; diarrheal diseases of infants, 42; meningitis, 35; influenza, 34; cancer, 148; accidents and violence, 181. There were two deaths from smallpox.

NEW JERSEY.

Board of Health Election.—At the annual meeting of the Atlanta City Board of Health Dr. John R. Fleming was elected president; Dr. M. Le Roy Somers, vice-president, and Dr. Edward Guion, secretary.

Deaths Exceed Births.—The report of the Bureau of Vital Statistics of Camden shows that during the year just closed there were 1,869 marriages, 1,497 births and 1,532 deaths, thus showing 35 more deaths for the year than births, provided all births were reported.

Personal.—Dr. Henry W. Elmer of Bridgeton sailed January 12 for Port Antonio, Jamaica.——Dr. Emery Marvel, Atlantic City, had a septic wound of the finger from the puncture of a *needle while operating, but is now rapidly recovering.*——Dr. Leslie L. Hand, Millville, is seriously ill with diphtheria contracted from repeated exposures to the infection in his practice.

A Useful Circular.—The Atlantic City Board of Health has issued a leaflet of information for the *family in case of contagious* diseases, which takes up plainly and concisely the general precautions to be observed, and then gives special recommendations regarding typhoid fever, scarlet fever, diphtheria, measles, whooping cough, mumps, chickenpox and disinfection. This is intended "not to supplant but to supplement the advice of the family physician."

Cooper Hospital Report.—The annual report of the Cooper Hospital, Camden, for 1904 shows that 1,040 patients were treated in the wards; 772 were discharged cured, 85 improved, 85 not improved, and 17 left without permission. There were 115 deaths, and of these 46 occurred within forty-eight hours from the time of admission to the hospital. The average stay of each patient was 17 days. In the dispensaries 4,593 patients were treated, and 13,571 revisits were made, making a total of 18,164.

Medical Inspector's Report.—The report of Dr. Henry H. Davis, medical inspector of the Camden public schools, showed the following communicable diseases reported for investigation during December: Diphtheria, 13; scarlet fever, 16; chickenpox, 11; measles, 9; tonsillitis, 19; ophthalmia, 5, and variola, 1. The report further shows that there was a decided increase in the cases of scarlet fever and diphtheria over the corresponding month of last year. He attributes the spread of the disease to its mild form, as it was not recognized and not treated.

Society Elections.—At the annual meeting of the Atlantic County Medical Society, January 13, Dr. Emery Marvel, Atlantic City, was elected president; Dr. Edward H. Madden, Absecon, vice-president; Dr. Edward Guion, Atlantic City, secretary and treasurer, and Dr. A. Burton Shimer, Atlantic City, reporter.——At the regular meeting of the Atlantic City Academy of Medicine, January 13, the following officers were elected: President, Dr. William E. Darnall; vice-president, Dr. Edwin H. Harvey; secretary, Dr. Walt. P. Conaway, and treasurer, Dr. J. Addison Joy. A committee on ways and means was appointed, consisting of Drs. Philip Marvel, William E. Darnall and W. Blair Stewart, to take steps toward the establishment of a first-class medical library.——At the annual meeting of the Burlington County Medical Society, held January 12, the following officers were elected: President, Dr. J. Howard Pugh, Burlington; vice-president, Dr. Frank G. Stroud, Moorestown; secretary, Dr. George T. Tracy, Beverly; treasurer, Dr. Enoch Hollingshead, Pemberton, and censors, Drs. Alexander Marcy, Jr., Riverton; Elmer D. Prickitt, Mount Holly, and Alexander H. Small, Riverside.

NEW YORK.

Many Insane.—While the *certified* capacity of the New York State hospitals for the insane is 22,000, the number of patients is 25,019. The most serious condition is on Ward's Island, where, with a capacity of 3,100, there are over 4,100.

Ithaca Water Supply.—A commission has been appointed by Justice Lyon of Binghamton to determine the value of the property of the Ithaca Water Works Company, lately condemned by the city of Ithaca, for the purpose of installing an artesian water supply.

State Charities.—The State Charities Aid Association held its annual meeting January 10. The annual report called especial attention to the overcrowding of the hospitals for the insane. A bill passed by the last legislature through the influence of this association provides for the establishment of a psychopathic hospital for the reception and examination of the alleged insane in New York City. It is hoped that this will, in a very large degree, obviate the stigma which now attaches to a commitment to an insane asylum, and that by *securing earlier treatment* of incipient cases of mental disease permanent commitment in a certain number of cases will be unnecessary.

New York City.

Fewer Street Accidents.—A decrease of 23 per cent. in the number of street accidents from those of last year is shown. This is attributed to the new scheme of traffic regulation and to the work of the mounted squad.

Increase in Pneumonia.—There were more pneumonia cases reported at the hospitals January 14 than on any previous day this winter. The number of cases now reported is above the average of normal years, though not so high as last winter, when 12,366 persons died of the disease.

Pneumonia.—Bellevue Hospital is crowded to overflowing with cases of pneumonia, bronchitis and influenza. At Roosevelt Hospital *there has been no such run of pneumonia cases.* This hospital, however, has had more applications than it could accommodate. One medical ward, accommodating 28 patients, has been closed for lack of funds.

Contagious Diseases.—There were reported to the sanitary bureau for the week ending January 7, 300 cases of diphtheria and croup, with 45 deaths; 282 cases of tuberculosis, with 168 deaths; 227 cases of scarlet fever, with 22 deaths; 122 cases of measles, with 11 deaths; 47 cases of typhoid fever, with 11 deaths; 138 cases of varicella, and 24 deaths from cerebrospinal meningitis.

To Prohibit Fireworks.—The chief of the fire department recommends that the sale of fireworks in this city be prohibited on July Fourth, because of the danger of numerous fires and because of loss of life and maiming of children. During the week of July 4, last year, 846 persons were taken *to the various hospitals suffering from injuries from fireworks.* This has been referred to the Municipal Explosive Commission.

Medical Society's Rights Questioned.—An application of importance has been made to Judge Leventritt, in the special term of the Supreme Court. It asserts that the law which gives the county medical society the fines imposed on persons prosecuted by its agents is unconstitutional. It is proposed to carry this case to the Court of Appeals. It has been asserted that benefits such as these conferred on the county medical society have already been pronounced unconstitutional. It *is held that the fines are the property of the state.*

New Red Cross Hospital.—This society is to have a new hospital which is to rival in completeness every other hospital in the city. William T. Wardwell has given $100,000 for the purchase of a site. John S. Huyler has donated all the brick necessary to construct the building, and an endowment fund has been started with a subscription of $3,000. Dr. A. Monae Lesser, who was surgeon-in-chief to the Red Cross Hospital during the Spanish-American War, will be surgeon-in-chief of the hospital. One of the objects of this institution will be to keep both physicians and nurses in readiness for government calls.

New York Water Supply.—James K. Apgar has a bill before the legislature excluding New York from tapping any of its streams in Westchester County for additional water supplies and also for repealing the Webster act, which enabled the city to secure land by condemnation for extension of its water-supply system. The passage of the Smith bill last year barred New York from seeking a water supply in Dutchess County, and it is stated that the representatives of Columbia and Ulster counties contemplate bringing in similar bills. These steps *seem to complicate* the difficulties of securing an adequate water supply for the city, but it is *hoped that* Governor Higgin's suggestion of appointing a state commission for the conservation of the waters of the Adirondacks and having also for its object the supply of water to the cities may hold the solution of this problem.

Buffalo.

Measles Epidemic.—There is no diminution in the number of measles cases in Buffalo. It is especially prevalent in the tenement districts among the Italians and Poles where exposure is almost a necessity because of overcrowding.

Personal.—Dr. H. Y. Grant has returned from Palm Beach.——Dr. Lawrence J. Hanley has been appointed obstetrician to the Maternity Hospital.——Dr. James Gallagher has been appointed visiting physician to the Emergency Hospital.——Dr

Charles S. Jewett has been elected president of the medical staff of the Sisters of Charity Hospital.——Dr. Benjamin Grove has been elected president of the Emergency Hospital staff.——Dr. Thomas Crowe has been elected chairman of the Board of Civil Service Examiners.

OHIO.

The Academy of Medicine of Toledo and Lucas County elected officers January 13 as follows: President. Dr. Thomas Hubbard; vice-president. Dr. Dice; secretary, Dr. Levison; financial secretary, Dr. Duncan; treasurer, Dr. John Keller; board of censors. Dr. Hasencamp; delegate to state society, Dr. Myers.

Personal.—Dr. Dwight B. Taylor, Madison, has been appointed surgeon to the Marion (Ind.) Branch, National Home for Disabled Volunteer Soldiers.——Dr. James W. Miller, Cincinnati, has been appointed district physician in place of Dr. William Muhlberg, resigned.——Dr. Louis Ransohoff, interne in the Cincinnati Hospital, sustained a fracture of the patella.

Consolidation of Medical Schools.—Dr. Charles Dabney, president of the University of Cincinnati, as the guest of the Cincinnati Academy of Medicine, January 9, delivered an address on "Medical Education," in which he expressed the hope that there would shortly be a consolidation of all the medical schools of the city, and the establishment of a medical college which could compete with the larger institutions in the East.

Danger of Contamination of Cincinnati's Water Supply.—The movement to dam the Ohio river at Cullom's Ripple has met with opposition from some, who claim that such a structure would cause contamination of Cincinnati's water supply. Dr. Byron Stanton, member of the Ohio State Board of Health, believes, on the contrary, and in this belief was sustained by other experts, that a uniform stage of water would greatly improve the drinking water.

Cincinnati's Sources of Tuberculosis.—At the regular meeting of the Cincinnati Society for Medical Research Dr. B. F. Lyle, in a paper on "The Sources of Tubercular Infection in Cincinnati," declared that infection of infants by way of the intestines and through the medium of cow's milk is seemingly rare; that the death rate from tuberculosis among school children is small, and that death certificates are not a true index of the frequency of deaths from tuberculosis.

PENNSYLVANIA.

Philadelphia.

New Surgeon for Howard Hospital.—Dr. Francis D. Patterson was elected surgeon to the Howard Hospital, vice Dr. Charles H. Frazier, resigned.

Osler's Portrait for the University.—The graduates of the Medical Department of the University of Pennsylvania who studied under Dr. Osler have taken steps to have a life-size portrait of their teacher painted and placed in the university. Graduates of the classes from 1885 to 1892 will assist in securing the painting.

Hospital Reports.—During December 4,670 patients were treated in the Medico-Chirurgical Hospital——Eighty-three patients were admitted to the Jewish Hospital in December, which, with 52 under treatment at the beginning of the month, made a total of 135; 68 were discharged cured, 13 improved and 1 died.——At the Mathilde Adler Loeb Dispensary 1,014 patients were treated.—At the Jewish Maternity Hospital 19 patients were admitted and 13 infants born.

Cancer Annex Opened.—The new cancer annex of the Home for Incurables was opened for the treatment of patients January 11. It is a three-story brick structure. The floors are of tile, the walls of cement, covered with enamel paint. There are 16 rooms for patients, 4 for nurses, a smoking room, 2 dining rooms, diet kitchen on each floor and separate lavatories for patients and attendants. At one end are verandas 12 feet wide and 40 feet long.

Personal.—Dr. Alexander C. Abbott was the guest at the annual meeting of the Kansas City Alumni Association of the University of Pennsylvania, January 6.——Dr. Albert P. Francine, under the auspices of the Henry Phipps Institute, spoke in Carnegie Hall, Pittsburg, January 12, on "To-Day's Crusade Against Consumption."—Dr. Milton J. Greenman was elected director of the Wistar Institute of Anatomy and Biology to succeed Dr. Horace Jayne, resigned.

Medical Club Elects Officers.—The Medical Club of Philadelphia held its annual meeting January 13 and elected the following officers: President, Dr. Roland G. Curtin; vice-presidents, Drs. Wharton Sinkler and Thomas G. Potter; secretary, Dr. J. Gurney Taylor; treasurer, Dr. L. H. Adler, Jr.; governor, for five years, Dr. James Van Buskirk, and executive committee, Drs. Ernest Laplace, Ernest Whitcome, Edward E. Montgomery, Walter L. Pyle and Alexander McAllister.

Bequests.—By the will of James Beckman, Doylestown, the Methodist Hospital receives $1,000.——A legacy of $2,000 was left by the will of Hannah Adler to the Jewish Hospital Association for the Mathilde Adler Loeb Dispensary.——By the will of William S. Bunting $500 was left toward the establishment of a free bed in the Episcopal Hospital as a memorial to his mother, and $500 to the Home for Incurables.——A check for $5,000 has been given to the Jewish Hospital Association by Samuel M. Fridenberg and children to endow a room in the hospital in memory of Mrs. Fridenberg.——By the will of Henry Norris $5,000 each was bequeathed to the Hospital of the University of Pennsylvania, the Pennsylvania and the Children's Hospital.

Health Report.—Pneumonia continues present in a highly malignant type, 80 deaths being due to that disease during the week. This is an increase of 18 over those of last week, and an increase of 11 over those of the week before. The total death rate was also somewhat increased, the total reaching 500, as compared with 478 last week and 736 for the corresponding period of last year. The principal causes of death were as follows: Diphtheria, 10; pulmonary tuberculosis, 52; cancer, 15; apoplexy, 25; heart disease, 54; pneumonia, 95; enteritis, 22; Bright's disease, 43, and accidents, 12. The total number of contagious diseases reported was 222, with 24 deaths, as compared with 236 and 25 deaths for the preceding week. There were no cases of smallpox reported.

GENERAL.

Biologic Station in the Bermudas.—Harvard and New York universities have agreed to conduct a biologic station in the Bermuda Islands for ten years.

The Charities of 1904.—The record for the past year shows that $62,000,000 has been given to charities in the United States. Of this sum it is estimated that hospitals have received $2,543,000. These figures are only approximate, being a compilation of published announcements.

Beri-Beri in America.—Two cases of beri-beri were discovered at the quarantine station at Marcus Hook January 8. The vessel came from Koanapali, Hawaiian Islands. The men were placed in the quarantine hospital and the crew in the detention wards and the ship was fumigated. This is the second time within a year that beri-beri has been discovered at the Philadelphia quarantine station.

Army Appropriation Bill.—January 7 the House Committee on Military Affairs practically completed the Army Appropriation bill. It carries, in round numbers, $69,000,000, which is about $3,000,000 less than the estimates and $5,500,000 less than the appropriations for the current year. For the construction and repair of hospitals, $315,000 was appropriated, a reduction of $75,000 from the previous year; for the medical and hospital department, $600,000 was appropriated, an increase of $40,000.

Yellow Fever Suspects.—The Panama Railroad steamship which arrived from the isthmus had on board Mr. Seager, secretary to Chief Engineer Wallace of the Panama Canal Commission, who was bringing the body of his wife, who died of yellow fever, home for interment. Mr. Seager is also supposed to have the disease and has been sent to Hoffman Island for observation.——The purser of the Ward line steamship *Vigilancia*, arrived from Havana, is supposed to be a victim of yellow fever and has been removed to Swinburne Island for observation.

Want to Release Lepers.—An attempt has been made in Hawaii to secure the release of certain lepers from the settlement at Molokai, the basis of the attempt being the contention that a person can not be deprived of liberty without due judicial process. Objection is made to imprisonment by administrative process. This refers to the custom of simply having a suspect inspected by the government physician, then sending the suspect to the receiving hospital where a board appointed by the Board of Health decides whether or not the case is one of leprosy and deals accordingly.

Bill to Incorporate American Medical Association.—The bill to incorporate the American Medical Association (H. R. 17335), was introduced in the House of Representatives, Jan. 9, 1905, by Mr. Dwight. The bill was referred to the committee on the judiciary and was ordered to be printed. It is as follows: A Bill to incorporate the American Medical Association. Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That Robert M. O'Reilly, doctor of medicine, Washington, D. C.; Presley M. Rixey, doctor of medicine, Washington, D. C.; Walter Wyman, doctor of medicine, Washington, D. C.; E. H. Gregory, doctor of medicine, St. Louis, Mo.; Henry O. Marcy, doctor of medicine, Boston, Mass.; Nicholas Senn, doctor of medicine, Chicago, Ill.; George M. Sternberg, doctor of medicine, Washington, D. C.: J. M. Mathews, doctor of medicine, Louisville, Ky.; W. W. Keen, doctor of medicine, Philadelphia, Pa.; Charles A. L. Reed, doctor of medicine, Cincinnati, Ohio: J. A. Wyeth, doctor of medicine, New York, N. Y.; Frank Billings, doctor of medicine, Chicago, Ill.; J. H. Musser, doctor of medicine, Philadelphia, Pa.; T. J. Happel, doctor of medicine, Trenton, Tenn.; Miles F. Porter, doctor of medicine, Ft. Wayne, Ind.; E. E. Montgomery, doctor of medicine, Philadelphia, Pa.; W. W. Grant, doctor of medicine, Denver, Colo.; H. L. E. Johnson, doctor of medicine, Washington, D. C.; A. L. Wright, doctor of medicine, Carroll, Iowa; William H. Welch, doctor of medicine, Baltimore, Md.; M. L. Harris, doctor of medicine, Chicago, Ill.; Philip Marvel, doctor of medicine, Atlantic City, N. J., and Lewis S. McMurtry, doctor of medicine, Louisville, Ky., and their successors, and those who may be associated with them, are hereby made and constituted a body politic and corporate by the name American Medical Association, with perpetual succession and power to take, for the purposes of its incorporation, by devise, bequest, grant, gift, purchase or otherwise, and hold or convey, both real and personal property and transact business anywhere within the United States. Sec. 2. That the object and purpose of such corporation shall be to promote the science and art of medicine and the public health throughout the United States. Sec. 3. That such corporation shall have power to make by-laws, rules and regulations, and choose officers for its government and the attainment of its purposes.

CANADA.

The Thunder Bay Medical Association was recently formed at Port Arthur, Ontario. The president is Dr. George W. Brown, Port Arthur; vice-president, Dr. W. W. Birdsall; secretary, Dr. H. E. Paul; treasurer, Dr. J. M. McGrady.

Fire in Royal Victoria Hospital, Montreal, January 14, did $40,000 damage. There were no fatalities. Lord Strathcona has cabled from London that he will bear the total cost of rebuilding the damaged portion. The number of patients admitted to the wards of this institution numbered during November 245; 229 were discharged and 11 died. In the outdoor departments there were 2,088 cases.

FOREIGN.

The Garcia Centennial.—The famous singing master, Manuel Garcia of London, who invented the laryngoscope fifty years ago, will be 100 years old March 17, 1905. The London Laryngological Society is collecting subscriptions for a present to be given to the venerable patriarch on that occasion.

German Congress for Amelioration of the Condition of Wage Earners.—The principal subject for discussion will be the protection of the workingman against industrial poisoning by enlightening him in regard to its dangers. The discussion will be opened with an address by L. Lewin. The congress will convene at Hagen June 6, 1905, and a number of the most prominent hygienists and medical authorities, as well as representatives of various industries, are actively engaged in its inception and promotion.

Plague in India.—The *Public Health Reports* state that with the advance of the cold weather, plague is again growing worse in Upper India. For the week ending December 3 the United Provinces had 4,425 deaths, an increase of 1,000 on the total of the previous week; the Punjaub, 2,446, an increase of 400; Mysore, 1,157, an increase of nearly 600; Hyderabad State, 768, an increase of 200. In the Bombay Presidency there were 6,770 deaths, an increase of 300. Elsewhere throughout India the disease remains about as before.

Fifth International Congress of Obstetrics and Gynecology.—The committee in charge of this congress has selected the following subjects for discussion: 1, Accouchement Forcé; 2, Operative Treatment of Fibromyomata of the Uterus; 3, The Vaginal Route in Obstetrics and Gynecology; 4, Critical Judgment of Operative Interventions in Case of Retrodisplacements of the Uterus, and 5. Chorio-epithelioma. The congress is expected to meet at St. Petersburg, Sept. 11-18, 1905. The chairman of the committee on organization is Prof. D. von Ott, Wassily-Ostow, University line 3, St. Petersburg. The committee has sent out a cordial appeal to all interested in obstetrics and gynecology to aid in making this congress a successful and memorable one.

Cure of Trachoma with Radium.—Herman Cohn, the well-known ophthalmologist of Breslau, writes to the *Berliner klin. Wochenschrift* of January 2 to report the rapid disappearance of the granulations in 3 cases of trachoma treated by exposure to radium. He used 1 mg. of radium bromid in a glass tube, 3 cm. long by 2 mm. in diameter, with daily exposures of ten to fifteen minutes. The granulations had been treated before with various measures by himself and others, without effect, while they were rapidly and painlessly banished by the radium, without a perceptible trace of any injurious consequences for the lid or the sight. These results confirm those obtained by R. Pardo of Turin in 2 cases of this hitherto intractable affection. His report was mentioned in The Journal of Sept. 17, 1904, page 850.

Ophthalmologist's Seal from Ancient Roman Colony.—Professor Ghirardini exhibited at a recent meeting of a Padua scientific society a seal which had been discovered in an ancient tomb at Este, the old Roman colony of Ateste. It is a fourfold seal, being square, with a different inscription on each side, signed with the name of the owner, Escagato, a physician of Greek origin. Each one of the inscriptions is the formula for some specific for eye affections. Two are for conjunctivitis and one for affections of the eye in general. The inscription was designed to be stamped on the collyrium made according to the directions of the formula, shaped, dried and hardened. Two fragments of these collyrium sticks were found with the seal, still bearing the imprint of the stamp and accompanied by some surgical instruments.

German Congress for Internal Medicine.—The twenty-second German Congress for Internal Medicine will convene at Wiesbaden, April 12-15, 1905. Professor Erb of Heidelberg will preside. The first day will be devoted to a discussion of "Heredity," with addresses by Ziegler of Jena on "The Present Status of the Question of Hereditary Transmission in Biology," and by Martius of Rostock on "The Importance of Heredity, Especially in Pathology and in Tuberculosis." Several communications have been announced on the treatment of leukemia with the Röntgen rays; by Schütz of Wiesbaden on "The Mucous Secretion of the Intestines;" by Matthes of Jena on "Autolysis," and by Clemm of Darmstadt on "Adhesive Plaster Supports in Treatment of Abdominal Viscera." Dr. E. Pfeiffer of Wiesbaden, Parkstr. 13, is secretary of the congress, which will be accompanied by an exhibition of instruments and appliances of interest to internal medicine.

New Poisons Law Wanted in New South Wales.—The Pharmacy Board of New South Wales has asked the government to provide a new poisons law. The old poisons act is now about 30 years old, and is said to be utterly inadequate for the requirements of the community. It does not prevent any person giving poisons away. Abortifacients may be given free of charge. Any person may sell any poison he likes, stating that he deals wholesale, and the law may not interfere, because the old law exempts wholesale dealing without stating what that shall mean. The *Australasian Medical Gazette* states that the proposed new act provides that no person shall be allowed to sell or give or supply poison of any kind unless he is licensed to do so. Ample provision has been made to issue licenses to dealers in poisons necessary for pastoral, agricultural and industrial purposes. A small fee has been provided to enable the board to carry out the provisions of the act. All licenses are to be renewed annually.

Successful Radiotherapy.—Lassar of Berlin presented an array of patients cured of cancer by modern methods of treatment which aroused great interest at the meeting of the German Cancer Research Committee on December 13. He exhibited a number of patients who had been cured for years of small, recent cutaneous cancer by arsenic internally. He says that this has never failed him under such conditions during twelve years' experience with it. He then marshaled 4 patients completely cured by Röntgen or radium treatment, some of them for years. Large cancroids vanish without exception under the *x*-rays, even those of long standing. Smaller ones, especially such growths on the lips, subside permanently under radium. He demonstrated a number of inoculation cancers which had been invariably cured. He also exhibited a number of patients cured of mycosis fungoides and fibrolipoma by the same measures, and also a large number of patients with sarcoma recurring after treatment by various other measures, the lack of permanent cure in these cases contrasting forcibly with the permanence of the results obtained with radiotherapy. A recent article by Lassar on the subject was reviewed in these columns on page 79. Béclère has been studying the radium rays in Curie's laboratory and announces a number of interesting points which he has learned in respect to dosage, etc. A report of his communication first comes to hand in the *Bull. Soc. Med. des Hop.*, December 22, No. 38. He finds the chromoradiometer a convenient means of determining the activity of radium, although the cutaneous reaction differs materially from that observed with the same dosage of Röntgen rays. He distinguishes between the true reaction, which sometimes does not appear until several weeks after the exposure, and the prereaction. He calls attention to the advantages of applying radioactive substances spread out in a thin, even layer between a square sheet of aluminum and one of platinum pivoting on a handle. By using a rectangular box of this kind it is possible to apply the rays evenly over a surface, none of the exposures overlapping or leaving gaps between them. He styles the radium salts "the pocket edition of the Röntgen tube," adding that they represent at the same time an extremely small and an extraordinarily soft tube. They are indicated chiefly for lesions of no great extent, either on the surface or in the depths, located at points difficult of access to the Röntgen rays. Danlos is convinced that the lack of penetration noted is due to the minute amounts of the radium salts employed. He has obtained effects on the screen through a silver dollar (five-franc piece), through a book with 1,000 pages, through a plank more than 2 cm. thick, and through his hand.

LONDON LETTER.

False Imprisonment (of Lepers) on a Large Scale.

Under the title of "False Imprisonment on a Large Scale," Mr. Jonathan Hutchinson protests in the *Times* against the detention of the lepers of Cape Colony in Robben Island, a rock-bound, sandy and treeless island near Capetown, as a blunder of pseudo-science and of a too credulous legislative authority. He compares this case with that of Mr. Beck, whose false imprisonment twice on a charge for which he has been shown to be innocent has created a great sensation in this country. It may be remembered that in his recent journey for the investigation of leprosy in South Africa Mr. Hutchinson visited Robben Island. Speaking from observation he says that the suffering which the lepers undergo in consequence of their detention is enough to make them wish for death. They sink into a condition of dull, hopeless apathy which knows no relief. Once a prisoner on the island a person is there for life. The leprosy law of Cape Colony consigns to that prison every one, without regard to sex, age or social position, who shows symptoms of leprosy in any stage or form. Release is only possible under a medical certificate of absolute cure. Until the last few years such certificates have scarcely ever been given and they are still very infrequent. Mr. Hutchinson points out that the creed that leprosy is contagious, which is held to justify this compulsory isolation, is with a certain definite exception refuted by a thousand facts. This exception is what he calls "commensal contagion"—taking food from a leper who has sores on the hands—a contingency which can easily be avoided.

Epidemic and Epizootic Plague.

An official report on plague by Dr. William Hunter, government bacteriologist in Hongkong, argues that the current views as to the etiology and pathology of the disease are erroneous. It is believed that the bacillus appears in the peripheral blood a few days before the fatal termination, that the bubonic is the typical variety of plague, that the bubo is an early manifestation of infection, and that gastrointestinal symptoms are of secondary importance. These views, it is urged, must be modified or discarded. The bacillus has been shown by Mr. J. Bell of the Government Civil Hospital, Hongkong, to be present in the peripheral blood from the initial stage of the disease. The application to plague of Ross' method of examining the blood in malaria shows that during the first or second day the bacillus can be found in numbers in the peripheral blood, in fact, before the bubo develops. This observation is confirmed by Dr. Hunter. This is opposed to the prevalent view that the bubo is an early if not an initial manifestation and an effort of the gland to arrest the bacillus. According to Dr. Hunter, plague is primarily a septicemia and the assumption of the bubonic, pneumonic or septicemic form is a secondary matter. Mr. Bell has found that by examination of the blood plague can be as easily diagnosed as malaria on the first or second day. The channel by which plague is conveyed to the human body, according to Dr. Hunter, is the gastrointestinal tract, and his evidence is very strong. If cases were seen at the earliest stage, before feverish symptoms have developed, in the vast majority diarrhea and vomiting would be noticed. Dr. Hunter also contends that pneumonic plague may be primary, i. e., that the bacillus may be inhaled. The importance of infection by the alimentary canal is great, for almost all domestic animals contract plague, birds are subject to it and, as proved by Dr. Hunter, flies, cockroaches and other non-suctorial insects harbor plague bacilli both on and within their bodies, rendering contamination of food easy. Dr. Hunter finds that epizootic plague always precedes epidemic plague, that the time between the initial cases of plague in the rat and in man is from 10 to 14 days, and that the disappearance of epizootic is followed in a week or two by the subsidence of the epidemic. Writing on the "Bridging of Epidemics," Dr. Hunter shows that plague in rats is present throughout the whole year, but that the disease becomes widespread at certain times of the year; in Hongkong during the first quarter of the year, and within a week or fortnight it becomes almost epidemic. Throughout the epizootic period the type of plague among rats is acute, but subsequent to the epizootic and epidemic periods and between the epidemics plague in rats occurs only in a chronic form. This explains the obstinate clinging of the disease to particular areas and its periodical recrudescence. About 75 per cent. of the rats caught alive are infected with chronic plague and the recrudescence of plague in rats in an acute form appears to depend on the infection of fresh generations of rats, the young animals being highly susceptible. Human plague is epidemic only during acute exacerbations of the epizootic and disappears or diminishes while chronic plague is present among rats.

Preservatives in Milk.

An important report on this subject has been presented to the Essex County Council by Mr. Dymond, lecturer on chemistry, Dr. Dyer, district agricultural analyst and joint public analyst, and Dr. Thresh, county health officer. The points considered by them were the effect of wet and dry weather on milk and the use of preservatives in dairy produce. With regard to the first question, they examined over 1,000 specimens and found that, although the richness of milk showed considerable variations, the average results were much above the limits of the Board of Agriculture and that there was no evidence that very dry weather or very wet weather produced any influence such as to render the board's limits unfair or onerous to the farmer. They were unanimous that it was to the interests of the farmer, as well as the consumer, that the board's regulations should be uniformly enforced. The use of preservatives was found to be unnecessary under the conditions of modern dairying with proper cooling appliances and due regard to cleanliness. The practice was further condemned as objectionable where infants are concerned. All the experts were of opinion that the use of preservatives in milk, including boracic acid and formalin, should be prohibited and that the quantities admissible in other dairy products should not exceed those permitted in the recommendations of the departmental committee.

Reformatories for Inebriates.

Dr. Branthwaite, inspector under the "inebriates act," has issued an instructive report for 1903 on the inmates of the reformatories provided under the act. The numbers have greatly increased in recent years as the working of the system is becoming appreciated. The number under detention at the end of 1903 was 1,012, against 88 five years before. Among these habitual drunkards there is a remarkable absence of the disease due to alcoholism. There has been one clear case of chronic Bright's disease. Many were suffering from symptoms of hepatic congestion, enlargement of the liver, slightly jaundiced conjunctiva and habitual constipation. But the symptoms disappeared under treatment. There was not one typical case of cirrhosis of the liver among these 1,000 worst drunkards in the country and no instance of ascites. Their mental condition was not so satisfactory. The majority were "feeble-minded," not amenable to jurisdiction as lunatics, but to a certain degree irresponsible. It would be difficult to find more than a third capable of passing muster as quite sane as compared with persons of average mental capacity.

Ice and Cold Storage.

The London County Council has issued a report on the fitness for consumption of ice sold in this country and conditions under which the cold storage business is conducted. Most of the ice used in London comes from small lakes and ponds in Norway, which are said to be situated in such secluded sites as to render contamination highly improbable. But it is by no means certain that the sanitary conditions at the harvesting grounds or the means of transfer and storage are satisfactory from the hygienic standpoint. The council, therefore, recommends that ice required for consumption or brought into contact with food should be that made artificially from pure and preferably from distilled water.

Correspondence.

Medical Society for the Study of Alcohol and Narcotics.

HARTFORD, CONN., Jan. 9, 1905.

To the Editor:—The American Medical Society for the Study of Alcohol and Narcotics will hold its annual meeting at Portland, Oregon, July 12, 1905. This society is composed of members of the American Medical Association who are especially interested in the study of the alcoholic problem and the diseases which follow. The purpose of the society is to study medically the clinical, etiologic, therapeutic and medicolegal aspects of this subject. Every year the increasing prominence of the diseases and the injuries due directly to alcohol make it more and more imperative for medical men to become familiar with the general principles of these neuroses and to be able to advise wisely the best means of prevention and cure. This society is trying to build up a new and broader interest in the subject among physicians to enable them to become teachers rather than followers of the public opinion of to-day. Several excellent papers have been promised for this annual meeting, and an earnest appeal is made to all medical men to take up this subject from a scientific point of view and to assist by their contributions or presence at the coming meeting. T. D. CROTHERS, M.D., Secretary.

Preparation of the Parturient Patient.

FORT STANTON, N. M., Jan. 9, 1905.

To the Editor:—Why is it that the great majority of obstetricians are so neglectful of surgical cleanliness as applied to the external genitals of women in labor? The gynecologist shaves and scrubs the external genitals for every minor operation, and the surgeon does the same even when his field is in the abdomen six inches from the nearest of the pubic hair But in a disgracefully large proportion of all deliveries no attempt whatever is made by the obstetrician to clean his field of operation, with the result of thousands of unnecessary deaths every year and an incalculable amount of chronic invalidism and sterility.

Location, anatomic conformation and functions of the vulva all combine to favor the accumulation there of a large and varied assortment of putrescible materials and pathogenic bacteria. Yet many an obstetrician allows his sterilized hand to come in contact with it at frequent intervals during labor, and so rubs bacteria into the stretching and splitting cervix. The full bath before labor is, of course, of some effect in reducing the possibilities of infection; but those familiar with surgical asepsis know that nothing but orthodox shaving and scrubbing can be relied on to prevent contamination of the birth canal during the examinations. It is not proposed to attempt to clean the vagina in ordinary cases. Theory and experience both show that the vagina can take good care of itself.

The passing of the finger through a septic vulva during labor is responsible for thousands of deaths and tens of thousands of cases of prolonged ill-health. That this state of affairs is still tolerated in obstetrics while it no longer is in surgery is due to a number of causes, not one of which is a real justification. In the first place surgery is practically a new art by reason of the revolutionary changes resulting from anesthesia and antisepsis; hence, patients expect surgeons to do things incomprehensible to the lay mind. But obstetrics, as many practice it, has changed little or none in the last fifty years. Every old woman considers herself a competent critic in the art, and frowns on all innovations, especially on those she can not understand or that make for her extra work. Thus, in contrast to the surgeon, whose patients come to him in a state of absolute helplessness, the obstetrician is often the most henpecked creature alive.

Fifty years ago the profession took a long step toward eradicating sepsis as a noteworthy cause of death after labor, and ever since has balked at the second and final one. Thanks to Holmes and Semmelweis, we no longer go from autopsies to deliveries without washing our hands. To remove the other constant source of infection, and so still further to reduce the mortality, it is necessary to scrub and to shave the vulva before labor, as the gynecologists do before an operation.

But it is easy to scrub one's own hands, while it requires more than ordinary tact and courage to succeed in inducing a frightened woman to submit to a disagreeable procedure which all her female friends assure her is unnecessary. Only by gradually and persistently educating the public and by arousing the conscience of the profession can this important reform be carried out. It is hoped that another Holmes with an inspired pen and another Semmelweis with an array of convincing statistics will come forward to do the work of awakening. In the meantime the rank and file of the profession will slumber on in the comfortable delusion that hand-scrubbing is the alpha and omega of obstetric asepsis and that the thousands of deaths and tens of thousands of cases of chronic invalidism from sepsis every year are an "irreducible minimum" and a necessary part of the curse of Eve.

NORMAN ROBERTS.

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed.

ALBUMINURIA.

BATH, ME., Jan. 2, 1905.

To the Editor:—In your answer, Dec. 31, 1904, to my query concerning the Spiegler-Jolles reaction, you say to filter the urine through asbestos. Do you mean asbestos paper? What is the character of this asbestos, and where can it be obtained?

HORACE FOX.

ANSWER.—Asbestos fiber comes in masses like cotton and should be readily obtained of any dealer in chemical supplies. The long fibers are best. Place a small, perforated porcelain disc in a funnel; suspend the asbestos in water and pour on the suspension until an even layer of asbestos is formed on the disc. The layer should be thick enough to yield a clear filtrate.

INJECTION TREATMENT OF HERNIA.

———, MINN., Jan. 4, 1905.

To the Editor:—Kindly give me the titles of about two good articles on the injection method for cure of inguinal hernia. Is this method used to any extent by reputable physicians?

MINNESOTA.

ANSWER.—Feid: "Treatment of Hernia by Injection," *Cincinnati Lancet-Clinic,* 1897, n. s., vol. xxxix, p, 182, Griffen: "Treatment of Inguinal Hernia by Injection," *International Journal of Surgery,* N. Y., 1897, vol. x, p. 355. Guim: "Injection Treatment of Hernia," *Texas Medical Journal,* 1900, vol. xvi, p. 71. These three are comparatively recent articles in English. A more elaborate article in German, "Treatment of Hernia with Alcohol Injections," by Steffen, may be found in *Samml. klin. Vortrage,* n. f., 1904, No. 369. The results of the injection treatment are so poor when compared with those of the modern operative procedures that the injection method finds little to recommend it.

SEQUELS OF GONORRHEA.

BROOKLYN, N. Y., Jan. 11, 1905.

To the Editor—In THE JOURNAL January 7, page 51, under the above heading, you answer the query in a way that gives an erroneous idea of the capabilities of the disease, inasmuch as you fail to mention any other than the acute—local—after-effects, and make no mention of the general life-long constitutional after-effects that most frequently result. These last are usually overlooked in the "years after," the physician usually ascribing same to other causes, when a careful study of the life history of a series of such cases would force a careful observer, if put on the right track, to conclude that gonorrhea is a constitutional disease with secondary and tertiary as well as hereditary manifestations, and that it is a frequent etiologic factor in a large percentage of chronic conditions. Some few of the chronic after-effects that may be most frequently noted are the following: Chronic catarrhal states, nasal, bronchial, gastrointestinal, and genitourinary; chronic rheumatic and neuralgic tendencies and states; morbid mental conditions of all kinds and degrees; passive congestions due to sluggishness of the venous system and producing first catarrhal states, to be followed secondarily by hyperplasia, and still later by fibrosis of structures involved; tendency to new growths both benign and malignant—anything from warts to cancer; marasmus and gastrointestinal diseases of infants, most frequently seen in the offspring of a gonorrheal parent. Many infants, when old enough to do so, will persist in "lying on face with knees drawn up under belly," and in every such case you may be positive that one of the ancestors has had gonorrhea.

W. H. FREEMAN.

ANSWER.—Our correspondent does well to realize as fully as he does the immense and protracted evil consequences of gonorrheal infection. He is not correct, however, in stating that we failed "to mention any other than the acute—local—after-effects." We mentioned several that are either not local or not acute. We purposely confined our answer to "the diseases and conditions usually included" because that was the question asked.

Marriages.

John W. Carico, M.D., to Miss Effie Hill, both of Cloverdale, Cal., December 30.

Asa N. De Vault, M.D., to Miss Mary Anderson, both of Chicago, December 21.

Guy A. Grafton, M.D., Hayward, Wis., to Miss Josephine Heyer of Superior, Wis.

Maurice Packard, M.D., to Miss Blanche Vogel, both of New York City, January 1.

Eugene F. Holland, M.D., to Miss Pearl Ingram, both of Mulberry, Tenn., January 4.

Eugene H. Smith, M.D., Ogden, Utah, to Miss Edith Burns of Omaha, Neb., January 4.

Walter M. Ely, M.D., to Miss Nora Ingle, both of Walla Walla, Wash., December 31.

D. D. Talcott, M.D., Crofton, Neb., to Miss Ethel Milner of Belvidere, Ill., December 27.

Edward C. Ledman, M.D., to Miss Zella N. Buchanan, both of Norwich, Ohio, December 28.

J. Maggard, M.D., Wichita, Kan., to Miss Erna Barteldes of Lawrence, Kan., December 31.

Joseph R. Anderson, M.D., to Miss Georgia Lewis, both of Owensboro, Ky., December 27.

Lee Wallace Dean, M.D., to Miss Ella M. Bailey, both of Iowa City, Iowa, December 29.

Roland H. Shippey, M.D., Rock, Kan., to Miss Angie Cecilia Gray of Denver, Colo., December 28.

Arville W. Bitting, M.D., Lafayette, Ind., to Miss Katherine Eliza Golden of Wollaston, Mass.

Robert W. O'Donnell, M.D., Monroe, La., to Miss Amelia Hardel of New Orleans, January 4.

Alfred R. Seebass, M.D., to Miss Herta Thies, both of Denver, at Cheyenne, Wyo., December 19.

L. Rollin Hudelson, M.D., Milroy, Ind., to Miss Maude Ellis of New Castle, Ind., January 4.

Edward Jenner Barrett, M.D., Chicago, to Miss Julia Dennett of Sheboygan, Wis., January 11.

Capt. Thomas Henry Mathews Clarke, R.A.M.C., to Miss Susan Morrell Chapin of Pennsylvania.

Lynn Moore Barnes, M.D., to Miss Donna Ullery Buckingham, both of Decatur, Ill., January 10.

Thomas M. Meriwether, M.D., Elberton, Ga., to Miss Nita Kendrick of Dawson, Ga., December 29.

Harry S. Prentiss, M.D., De Soto, Mo., to Miss Edith Garsides of Little Rock, Ark., December 27.

W. V. Stanfield, M.D., West Point, Ind., to Miss Edith Closson of Newtown, Ind., December 28.

Charles F. McComb, M.D., to Miss Helen Jensen, both of Duluth, at Stillwater, Minn., January 17.

Homer Sylvester, M.D., Milwaukee, Wis., to Miss Janette Atwood, at Edgerton, Wis., December 21.

E. Van Camp, M.D., Butler, Mich., to Miss Bessie May Gates of Red Wing, Minn., December 29.

Charles Bernstein, M.D., Rome, N. Y., to Miss Lillian Watson Stebbins of Warsaw, N. Y., January 3.

George B. M. Bower, M.D., Fort Wayne, Ind., to Miss Lillie Weld of Guthrie Center, Iowa, December 26.

Thomas A. Buchanan, M.D., Oklahoma City, Okla., to Miss Winifred Brown of Virginia, Ill., January 3.

Clyde Van Osdol, M.D., Milan, Ind., to Florence M. Olmstead, M.D., of Versailles, Ind., December 29.

Louis Fuldner, M.D., Milwaukee, to Miss Carolyn Elizabeth Blanchard of Lake Geneva, Wis., December 28.

John Randolph Jordan, M.D., Ellaville, Ga., to Miss Elizabeth Williams of Buena Vista, Ga., December 31.

Edward Thomas Lawler, M.D., Cedar Rapids, Iowa, to Miss Laura Mae Green of West Union, Iowa, January 17.

Christian Waldkoenig, M.D., Baltimore, Md., to Miss Florence Aurora Mills of Douglasville, Ga., December 29.

William Charles Schroeder, M.D., Portsmouth, Va., to Miss Margaret V. Hill of Raleigh, N. C., December 29.

William Wallace Ralston, M.D., Houston, Texas, to Miss Ella Kate McCollum of Lockport, N. Y., December 28.

Leander Armistead Riley, M.D., Oklahoma City, Okla., to Miss Gertrude Darrall of Galveston, Texas, January 11.

Joseph B. Hardy, M.D., St. Louis, Mo., to Miss Minnie B. Withers of Topeka, Kan., in Kansas City, Mo., January 3.

Deaths.

Churchill Carmalt, M.D. College of Physicians and Surgeons in the City of New York, 1891, a member of the American Medical Association, New York State Medical Association, Association of American Anatomists, and New York Academy of Medicine; assistant surgeon at the Woman's Hospital; one of the founders of the Hudson Street Hospital; demonstrator of anatomy in the College of Physicians and Surgeons; formerly assistant to the late Dr. T. Gaillard Thomas; a gynecologist of repute, died at his home in New York City, January 8, from pneumonia, after an illness of three days, aged 39.

William H. Prioleau, M.D. Medical College of the State of South Carolina, Charleston, 1893, a member of the American Medical Association; formerly acting assistant surgeon in the United States Public Health and Marine-Hospital Service; a member of the Mississippi Valley Medical Association, Medical Society of the State of North Carolina, and Buncombe County Medical Society, formerly of Asheville, N. C., died at his home in Charleston, S. C., January 4, after a long illness, aged 35.

James Walter Hervey, M.D. Indiana Central Medical College, Indianapolis, 1850, surgeon of the Fiftieth Indiana Volunteer Infantry in the Civil War; one of the oldest members of the Indiana State and Marion County medical societies; a member of the legislature in 1854; delegate to the International Medical Congress in 1892, died at his home in Indianapolis, January 5, from a severe cold, after an illness of three days, aged 85.

Henry Mallery, M.D. Medical Department of Western Reserve University, Cleveland, 1850, president of the Board of Health of Hamilton, Ohio, and one of the oldest practicing physicians in the state, died at his home, December 21, from pneumonia, after an illness of two days, aged 82. He served as surgeon to the Fourth Kentucky Infantry and afterward as division surgeon during the Civil War.

Warren Hunter, M.D. Medical School of Maine at Bowdoin College, Brunswick, 1860, physician of Rock Island County for six years, assistant surgeon of the One Hundred and Sixteenth Maine Volunteer Infantry during the Civil War, died at his home in Oneida, Ill., January 6, from uremia, aged 72.

Joanis Orlando Harris, M.D. Geneva (N. Y.) Medical College, 1851, assistant surgeon of the Fifty-third and One Hundred and Thirty-eighth Illinois Volunteer Infantry in the Civil War, died at his home in Ottawa, Ill., January 10, from pneumonia, after an illness of only one day, aged 76.

George V. Convery, M.D. Long Island College Hospit Brooklyn, N. Y., 1880, for many years surgeon in the marine and later inspector of the Brooklyn Depart

Health, died at his home in South Brooklyn, N. Y., January 7, after an illness of four months, aged 44.

Richard Kidder Taylor, M.D. Medical College of Virginia, Richmond, 1846, medical purveyor in the Confederate service during the Civil War, died at his home in Keokuk, Iowa, January 6, from heart disease, after an illness of two months, aged 78.

D. Albert Barnum, M.D. Albany (N. Y.) Medical College, 1865, assistant surgeon in the Sixteenth New York Heavy Artillery during the Civil War, died at his home in Cassville, N. Y., from gastritis, January 1, after an illness of a few hours, aged 59.

Frank Chambers, M.D. University of Louisville Medical Department, 1875, a member of the American Medical Association and one of the best-known physicians of Hancock County, Ky., died at his country home near Chambers, January 5, from dropsy.

Harry D. Quarry, M.D. Trinity Medical College, Toronto, Ont., 1889, some-time secretary of the North Dakota State Board of Health, a specialist on the eye and ear, died at Mentone, Cal., December 27, from tuberculosis, after a long illness.

William A. Norred, M.D. College of Medicine and Surgery of the University of Minnesota, Minneapolis, 1902, committed suicide in his rooms in Minneapolis, January 12, by shooting himself through the heart while despondent, aged 34.

E. B. Freeman, M.D. Jefferson Medical College, Philadelphia, surgeon in the Confederate service during the Civil War, died at his home in East Rome, Ga., January 6, from the effects of carbolic acid accidentally administered, aged 74.

Edmund C. Purcell, M.D. Missouri Medical College, St. Louis, 1887, a member of the American Medical Association, died at his home in Elyria, Denver, Colo., from pneumonia, after a short illness, January 3, aged 49.

Frank L. Connerly, M.D. Tulane University of Louisiana Medical Department, New Orleans, 1894, of Lake Village, Ark., was accidentally shot and killed while hunting near McGehee, Ark., December 20, aged 48.

Carl V. Scheuermann, M.D. Western Pennsylvania Medical College, Pittsburg, 1894, clergyman and physician, died at his home in Pittsburg, January 4, from pneumonia, after an illness of five days, aged 42.

John Hill, M.D., assistant surgeon of the Forty-first Ohio Volunteer Infantry in the Civil War, died at Vincennes, Ind., December 27, from cerebral hemorrhage, after an illness of two months, aged 62.

Noble C. McMorris, M.D. Department of Medicine of the University of Pennsylvania, Philadelphia, 1856, died at his home in Duncannon, Pa., December 27, from pneumonia, after a short illness, aged 68.

George P. Dobson, M.D., one of the oldest practitioners of Dickson County, Tenn., died at his home in White Bluff, December 31, from paralysis, after an illness of three days, aged 70.

James Edward Kempf, M.D. University of Louisville Medical Department, 1878, of Jasper, Ind., died at St. Anthony's Hospital, Louisville, January 8, after on operation for appendicitis, aged 48.

Achille Chouinard, M.D. Laval University Medical Department, Quebec, 1902, recently returned from studying in France, died at his father's home in Quebec, October 11, from tuberculosis.

Alfred Tygesson, M.D. University of Lund, Sweden, 1891, a morphin habitué, committed suicide at his home in Hartford, Conn., January 6, by taking 25 grains of morphin, aged 48.

Roosevelt H. Davis, M.D. University of Michigan Department of Medicine and Surgery, Ann Arbor, 1852, died at his home in Eaton Rapids, Mich., January 7, aged about 80.

Charles A. McNulty, M.D. The College of Physicians and Surgeons of Chicago, 1887, committed suicide by shooting himself in his room at Harlem, Mont., Oct. 6, 1904.

John Reynolds Pomeroy, M.D. Toronto University Medical Faculty, 1878, died at his home in St. Louis, December 30, from septicemia following mastoid abscess, aged 55.

Joseph L. Hillmantel, M.D. Northwestern University Medical School, Chicago, 1887, formerly of Milwaukee, but more recently of Missoula, Mont., died December 21.

William de la Fletcher Ward, M.D. San Francisco, 1894, died from ptomain poisoning at his home in Santa Rosa, Cal., January 6, after an illness of two days, aged 53.

James W. Agee, M.D. St. Louis Medical College, for forty years a practitioner of Valley, Neb., died at his home in that place from pneumonia, January 8, aged 71.

Cyrus McCormick, M.D. University of Maryland School of Medicine, Baltimore, 1868, died at his home in Berryville, Va., January 3, after a long illness, aged 59.

Charles W. Goodale, M.D. Rush Medical College, Chicago, 1869, died at his home in Metz, Ind., from kidney disease, after a long illness, January 5, aged 60.

Jennie Brooks Hildebrand, M.D. Woman's Medical College of Pennsylvania, Philadelphia, 1870, died from pneumonia at her home in San Francisco, January 7.

David S. Minton, M.D. New York University, New York City, 1878, died at his home in New York City, January 2, from cerebral hemorrhage, aged 65.

W. P. Hough, M.D. Tulane University of Louisiana, New Orleans, 1883, of Columbia, La., died in Monroe, La., January 3, after an illness of several months.

William C. Cox, M.D. Cincinnati, 1848, died at his home in East Nashville, Tenn., January 6, from senile debility, after an illness of seven months, aged 88.

Peter Reid McMonagle, M.D. University of Vermont Medical Department, Burlington, 1859, died at his home in Prescott, Ont., December 20, aged 71.

George H. Cagle, M.D. St. Louis Medical College, 1875, of Mandeville, Ark., was shot and killed while hunting near Texarkana, January 8, aged 60.

Peter J. McCormick, M.D. New York University, New York City, 1858, died at his home in Yazoo City, Miss., January 3, from cerebral hemorrhage.

Henry Martyn Wells, M.D., medical director United States Navy from 1861 to 1897, died at his home in New York City, January 12, aged 70.

Andrew J. Brewer, M.D. University of Louisville Medical Department, 1879, of Muskogee, I. T., died December 30, at San Diego, Cal., aged 58.

George W. Gillette, M.D. University of Buffalo (N. Y.) 1888, died suddenly at his home in Buffalo from heart disease, December 17, aged 55.

Samuel B. Shaw, M.D. Beaumont Hospital Medical College, St. Louis, 1901, of Bowesmont, N. D., died recently in a hospital in Minnesota.

James J. Kerr, M.D. Cincinnati, 1878, died at his home in Cincinnati, Iowa, December 29, after an illness of several months, aged 84.

Jerome H. Hardcastle, M.D. Medical College of Virginia, Richmond, 1865, died at his home in Middletown, Del., December 31, aged 64.

M. W. Coffman, M.D. Colorado School of Medicine, Boulder, 1900, of Boulder, Colo., died in Denver from tuberculosis, June 9, 1904.

Hugh L. Ray, M.D. Years of Practice, Kentucky, 1894, of Vaughan's Mills, Ky., died suddenly in Bellevue, Ky., January 10, aged 68.

Axel M. Anderson, M.D. Cincinnati, 1899, of Erie, Pa., died recently in Chicago, and was buried in Jamestown, N. Y., December 28.

Monroe Wilkinson, M.D., formerly of New Haven, Ky., died at his home in Louisville, Ky., December 31, from pneumonia, aged 67.

J. L. Vowell, M.D. Missouri Medical College, St. Louis, 1878, formerly of Sunset, Texas, died at Bowie, Texas, December 28, aged 70.

James D. Landrum, Years of Practice, Kentucky, 1894, died at his home in Mayfield, Ky., January 9, from senile debility, aged 82.

Isaac Nock, M.D. Pennsylvania, 1867, died at the Canton (Ohio) County Infirmary, December 27, from pneumonia, aged 77.

James I. Ferron, M.D. Keokuk (Iowa) Medical College, died at his home in Council Bluffs, Iowa, December 28, from pneumonia.

William Harper Davis, M.D. New York City, 1896, died at his home in Brooklyn, January 8, after a long illness, aged 33.

John Lucas Meriwether, M.D., of Mathews Station, Ala., died at a private sanitarium in Atlanta, Ga., January 2, aged 55.

W. D. Young, M.D. College of Physicians and Surgeons, Baltimore, 1889, of East Durham, N. C., died Sept. 25, 1904.

John H. Crawford, M.D. St. Louis, 1879, died at his home in Santa Monica, Cal., after a long illness, Nov. 1, 1904.

John Greenbank, M.D. Pennsylvania, 1853, died at his home in Ocean Grove, N. J., December 29, aged 75.

R. Frank Eagon, M.D. Louisville Medical College, 1889, died at his home in Crawford, W. Va., January 2.

George L. Freeman, M.D. Ohio, 1852, of Glen Head, Long Island, N. Y., died December 27, aged 75.

Joseph A. Moke, M.D. Pennsylvania, 1870, died at his home in Crosswicks, N. J., January 1, aged 65.

William F. Stewart, M.D. Illinois, 1890, of Wabash, Ind., died January 8, in Indianapolis.

Book Notice.

DISEASES OF THE LIVER, GALL BLADDER AND BILE DUCTS. By H. D. Rolleston, A.M., M.D. (Cantab.), F.R.C.P., Physician to St. George's Hospital, London. Fully Illustrated. Including Seven Colored Insert Plates. Cloth. Pp. 794. Price, $6.00 net. Philadelphia, New York, London: W. B. Saunders & Co. 1904.

One is prepared to welcome a good book, especially one in English, on diseases of the liver. Budd, Harley and Murchison are out of date; the more recent work of Quincke and Hoppe-Seyler in Nothnagel's series is not entirely satisfactory. Probably books on this subject are not more numerous because there is still so much that is vague and misty in the physiology, pathology, and pathologic chemistry of the liver, and so much that is unsatisfactory in the matter of treatment. But disease of the liver is a something that is real and that has to be reckoned with by every practitioner, and a reliable guide is a necessity; such a guide will be found in Rolleston's work. The book is eminently practical; it is not overbalanced with theory, in fact we may question whether the author has acted wisely in some instances in omitting certain theories. Rolleston's contributions to the subject of the pathology and clinical course of diseases of the liver during the last decade have been numerous and he is known as a careful observer and a clear writer. These characteristics are seen in this book. A due sense of proportion prevails, not only in the space devoted to different diseases but in that devoted to the subheads under the various diseases. He lets no hobby run away with him; he does not fill pages with the exploiting of some pet notion. The case histories that are inserted, and there are many of them, are truly illustrative, concisely given and never obtrusive. The book is up to date. Such conditions as pericarditic pseudocirrhosis, hemachromatosis, Bante's disease, etc., are fully discussed. The author appreciates the difficulties of satisfactorily classifying the cirrhoses; he states the case fairly, including the modern views, gives various classifications, such as those of Adami and the elaborate one of Chauffard, as well as his own, and then sensibly comes back to the old clinical classification of the portal and biliary types of the disease, not by any means exact, but still workable. It is a pleasure to note the recognition of American and French writers. English writers are, of course, freely cited. We have become so accustomed to see in the bibliographies such a long string of German titles that it is a pleasant surprise, almost a shock, to read a list of ten or fifteen names that includes, perhaps, but one or two German ones. We trust our author has not gone too far in this respect. For while our German confrères are extremely aggravating and shortsighted, too, in the way in which they largely ignore work done elsewhere than in Germany, we do not gain by ignoring them; rather do we injure ourselves.

Miscellany.

The Army Medical Service.—The bill to increase the efficiency of the Medical Department of the United States Army has passed the Senate and is now before the House of Representatives. On January 9 the President of the United States sent the following message to Congress:

To the Senate and House of Representatives:

I have, in a former message, stated to the Congress my belief that our Army need not be large, but that it should in every part be brought to the highest point of efficiency. The Secretary of War has called to my attention the fact that the act approved Feb. 2, 1901, which accomplished so much to promote this result, failed to meet the needs of one staff department, in which all of our people are peculiarly interested and of which they have a right to demand a high degree of excellence. I refer to the Medical Department. Not only does a competent medical service by safeguarding the health of the Army contribute greatly to its power, but it gives to the families of the nation a guaranty that their fathers, brothers and sons who are wounded in battle or sicken in the camp shall have not only skilled medical aid, but also that prompt and well ordered attention to all their wants which can come only by an adequate and trained personnel.

I am satisfied that the Medical Corps is much too small for the needs of the present Army and therefore very much too small for its successful expansion in time of war to meet the needs of an enlarged Army, and, in addition, to furnish the volunteer service a certain number of officers trained in medical administration. A bill which, in the opinion of the Secretary of War, of the late Secretary of War, and of the General Staff of the Army, supplies these deficiencies was introduced at the last session of Congress and is now before you. I am also advised that it meets the cordial approval of the medical profession of the country. It provides an organization which, when compared with that of other nations, does not seem to err on the side of excessive liberality, but which is believed to be sufficient. I earnestly recommend its passage by the present Congress. If the Medical Department is left as it is, no amount of wisdom or efficiency in its administration would prevent a complete breakdown in the event of a serious war.

I transmit herewith a memorandum which has been prepared for me by the Surgeon General of the Army, and also the remarks of the former and of the present Secretary of War with reference to this bill.

It is reported to me that the Ordnance Corps is in a position of disadvantage; that its personnel is inadequate to the performance of the duties with which it is charged, and that under existing conditions it is unable to recruit its numbers with officers of the class necessary for the conduct of its very technical work. It is unnecessary for me to lay stress on the desirability of having the design and manufacture of the material with which we are to fight in competent and sufficient hands, as there is no difference of opinion as to the intention of all concerned to have provided a proper supply of weapons, munitions, engines of war, equal in conception and construction to any in the world, and superior in any respects in which by skill and attention we may be able to compass such superiority.

The greatly increased utilization of the exact sciences in ordnance construction requires a larger personnel for their application, and the process of its selection should be severely and continuously discriminating, under conditions offering stimulus sufficient to cause officers of proper capacity, of whom it appears there are plenty, to wish to subject themselves to it A bill embodying the necessary provisions and involving no radical departure from existing methods has been prepared by the War Department. I think it should be passed.

THEODORE ROOSEVELT.

The following is Surgeon-General O'Reilly's memorandum sent to the President Dec. 7, 1904:

The fact that mortality from disease in armies in war time greatly exceeds that from losses in battle is well known. The noneffective rate from sickness is even more greatly in excess of that from wounds. The British army in the Peninsula, in spite of the many bloody battles, lost three times as many men from disease as from wounds. The infant French Republic was saved at Valmy more by the paralysis of Prussian efficiency by ravage of disease than by that rather bloodless victory. General Scott in the Mexican war lost by disease one-third of his effective strength. The loss from disease in the civil war was more than double that from the casualties of battle. The military efficiency of newly raised armies is specially liable to be gravely compromised or even destroyed from this cause.

The three primary duties of the Medical Department are:

1. To preserve the effective strength of armies (military sanitation).
2. To care for the sick and wounded.
3. To conduct the administrative work of the department.

To carry out these objects requires a highly specialized and complex organization and a numerous trained personnel. Military sanitation is now recognized to be a well-marked specialty in medicine of which the average [illegible] ittle more than he does of the methods of [illegible] ministration. The second duty is that for whic [illegible] can be used to advantage, while the first and third must in the main be in the hands of trained medical officers in order to secure efficiency. The standard of what is regarded as a satisfactory degree of efficiency in all of these directions has been greatly raised in late years.

In the Spanish war the country was scandalized by a monthly death rate from disease which rose from 2.15 per thousand in July to 4.08 in August, but fell again to 2.45 in September. During the civil war a higher death rate from disease than the highest maximum above mentioned persisted for many months, reaching in the spring of 1862 a maximum more than double it, without creating half as much popular clamor.

Nor would such occurrences be possible now in civilized warfare as for 600 wounded to lie for more than ten days on the battlefield, as happened after the second battle of Bull Run, on Aug. 30, 1862, when many of the wounded died of starvation. That this was not one of the unavoidable horrors of war, but was, as stated by the Surgeon General in reporting these facts, due to defective medical organization is evidenced by the fact that after the organization of the ambulance service of Letterman such occurrences ceased in the Army of the Potomac. After the great battles of Fredericksburg, Dec. 13, 1862, and Chancellorsville, May 2, 1863, for instance, although the Army was defeated, the field was cleared of wounded without confusion or delay.

The public sentiment of the civilized world therefore demands better organization and higher efficiency for the medical department of armies than at any time heretofore. Other nations, including even so poor a nation as the Japanese, are willing to pay the cost of increased efficiency in the shape of a large and well organized medical service, and it is not to be believed that Congress or the American people will refuse for our Army what is demonstrated to be essential to avoid future failure and insure efficiency. For medical efficiency a certain number of trained medical officers is necessary to direct matters of military sanitation, and, in the words of Mr. Root, "to conduct the administration of the great and complicated medical service." The measure of this number is given by the Secretary of War in his report for this year as follows (p. 25):

"It is evident that a staff department which has a personnel insufficient to perform the duties required of it in time of peace can not be successfully expanded to meet the increased responsibilities of war. The commissioned personnel of the Medical Department is nearly 200 short of the number required to perform its work at present, and the deficiency has to be made good by the employment of civilian physicians under contract. This is an expensive and unsatisfactory expedient in time of peace, while in time of war it heavily handicaps the efficiency of the department."

This principle was not recognized in the reorganization of the Army in 1901. The increase in the Medical Department at that time was so inadequate that the proportion of medical officers to the Army at large was not increased, but greatly diminished and was made considerably less than the proportion existing at the beginning of the Spanish war or the civil war—this in spite of the recommendation of the Dodge Commission that the regular corps be increased.

Instead of giving an advocate's discussion of the bill now before Congress I prefer to refer the President to the impartial opinion of the experts of the Third Division of the General Staff as given in their report on it made to the Chief of Staff, which is to be found on pages 6, 7 and 8 of the report of the Senate Military Committee. (Report No. 2420.)

The attention of the President is especially asked to the following points:

The Army is to-day officered for a strength of 100,000 men except the medical departments, which is only sufficient for 42,000.

An adequate increase in the Medical Corps was recommended by the Dodge Commission.

This bill offers, in the words of Secretary Taft, "a complete workable system."

With a less number than asked for, the Medical Department can not perform the duties with which it is charged by Army Regulations in time of peace, or be successfully expanded to meet the increased labors and responsibilities of war.

With a less proportion in the higher grades it can not attract properly qualified candidates to fill the vacancies created.

The Reserve Corps constitutes an eligible list of competent civil physicians who will reinforce the regular Medical Corps in time of war or other emergency.

The increase of cost is, when the enlargement is completed four years hence, only a little over 4 per cent. above the present cost of the Medical Corps, while next year it will be actually diminished under this act.

The increase of efficiency is as 320 is to 450, or about 40 per cent.

The bill has received the rigid scrutiny of the General Staff and the approval of Secretary Root, of Secretary Taft, of the Military Committee of the Senate, and of the American Medical Association.

Respectfully submitted, R. M. O'Reilly,
Surgeon General.

Mr. Bassett of New York, in discussing this subject, said that some attention should be given to the life-saving departments of the Army as well as to the life-destroying departments. He stated that in the civil war 80 per cent. of those who died succumbed to preventable disease. In the Spanish-American war, on the American side, thirteen men died from preventable disease for every one who died in battle or from wounds received in battle. He then compared this with the illustration furnished by the Japanese army and quoted Major Seaman, who studied the Japanese methods in the field, as follows:

> Too much praise can not be bestowed on the medical departments of the army and navy for their splendid preparatory work in this war. The Japanese are the first to recognize the true value of an army medical corps. Care of the sick and wounded consumes but a small part of the time. The solution of the greater problem, preserving the health and fighting value of the army in the field—by preventing disease, by careful supervision of the smallest details of subsisting, clothing, and sheltering the units—is their first and most important duty. Their capacity for detail is something phenomenal; nothing seems too small to escape their vigilance or too tedious to weary their patience, and everywhere—in the field with the scouts or in the base hospitals at home—the one great prevailing idea is the prevention of disease. The medical officer is omnipresent. You will find him in countless places where in an American or British army he has no place. He is as much at the front as in the rear. He is with the first screen of scouts with his microscope and chemicals, testing and labeling wells so the army to follow shall drink no contaminated water.

Mr. Bassett went on to say that in the American Army not only is the Medical Corps insufficient, but they lack authority. A great many physicians who enter the Army, especially in time of war, are on temporary contract. They are called "contract doctors," and it has been held in a court-martial that they do not have authority, not being commissioned officers, and yet those who are regularly commissioned in the Army are so few in number that they can not do the sanitary work in advance that is done in the Japanese army; they can not do the chemical and biologic work that would save thousands of lives, and the result is that preventable diseases have wiped out a far greater number than the bullets of the enemy.

Mr. Bassett believes that the Medical Corps must have sufficient numbers and sufficient authority to enforce their orders in regard to sanitary regulations.

THE CHRISTIAN HOSPITAL FRAUD.

Report by the Medicolegal Committee of the Chicago Medical Society.

Decision Against the Christian Hospital and N. News Wood for Contempt of Court.

On May 17, 1903, Dr. J. B. Murphy came to the office of the Medicolegal Committee with a package of letters received from physicians of the West and Southwest. The writers of these letters had received announcements from the Christian Hospital, bearing Dr. Murphy's name and picture. They were indignant that Dr. Murphy should be a party to this scheme and they so wrote—sometimes in kindness and sometimes in hot, abusing anger. In the lot was a letter on the hospital paper bearing Murphy's picture and his name, asking him to join the staff; this was dated May 12. It was apparent that many of the circulars had been issued prior to May 12, since many replies were written Murphy under date of May 12, or earlier. Dr. Murphy asked the help of the Committee. We began an investigation. The following is a synopsis of the main points covered:

The plan of procedure of the Christian Hospital originated with A. C. Probert. Its details were executed by N. News Wood. Probert spent his earlier life in New Jersey. His first operations in the West were in northern Wisconsin. He did not then claim to be a physician. He had business careers in Ashland and vicinity, and finally landed in the Wisconsin penitentiary at Waupun. On his release he came to Chicago. We have no certain knowledge of his business until he appeared as Dr. Probert of St. Luke's Hospital of Niles, Michigan. That institution placed Dr. Senn's name on its literature. Dr. Senn publicly disclaimed the relation. Use was then made of the name of Dr. Kinsman of Boston, who published an affidavit setting forth that the use of his name was without authority. There were some complications as to women, notice of which appeared in the Chicago daily papers, and Chas. W. H. B. Granville left for the Southwest. Public sentiment and the Michigan authorities were too much for St. Luke's of Niles, under the Probert-Granville management. Probert went a few miles over the line to Bourbon, Ind. He carried a letter from a Niles citizen since then arrested. He opened a bank at Bourbon. In a short time the bank failed. In 1903 indictments against Probert were still in existence in that county. A former editor of a Bourbon paper gave us the above facts. Probert told our informant that he intended coming to Chicago to work the physicians with a scheme similar to that of St. Luke's of Niles. He came to Chicago and went in with Wood on the Christian Hospital proposition. In June, 1903, he was arrested by the postal authorities for using the mails to defraud. His picture in prison garb, with a sketch of his career, was in the Chicago papers. In the same month he opened a bank at Eau Claire, Michigan, a small town near Chicago, supplied by the Chicago papers. In October, 1903 the Chicago papers contained an account of the suspension of this bank. In November, the United States courts found him guilty and fined him $500. He then went to New Mexico. In the spring of 1904 the Chicago papers announced the failure of his bank in New Mexico. He is said to be in Michigan now. Dr. Wood we first hear of as having a lying-in hospital at Des Moines, Iowa. Later he had another institution at Omaha. We were given a list of people, three of whom lived in Chicago, and the remainder in Iowa and Nebraska, who could tell us of the conduct of these institutions. None of these people responded to inquiries. Dr. Wood came to Chicago about 1892. He opened a hospital on La Salle avenue. The steps in the evolution of the Christian Hospital are set forth clearly in Judge Holdom's decision.

On Monday, May 18, Dr. Murphy and this committee conferred with State's Attorney Deneen. It was agreed that the

United States could get evidence more easily than could the State. We then conferred with United States Inspector Stewart. His men went to work at once. Evidence was gathered until June 1, when Wood and Probert were arrested. On June 2, Inspector Ketcham told us that the government had enough evidence. On June 3, Judge Holdom enjoined the institution and its officers from alleging that Dr. Murphy was, or ever had been, connected with the Christian Hospital, also from selling any more certificates bearing his name or picture, or from sending out advertisements similar to those formerly used. In March, 1904, Dr. Murphy received a large number of complaints that the Christian Hospital was again using his name. Especially kind letters were written by Drs. Crysler of Yazoo City, Miss., Murphy of Enterprise, Miss., and Persons of Montgomery, Ala. These letters came principally from the South. It was apparent, then, to all of us, that denials such as those of Drs. Senn, Kinsman, Delafield, Deaver, and Bernays, and even the more active course of Dr. Murphy and our committee during 1903, were ineffective. Mr. Dacy, the very able attorney of the Society, who had handled the case originally, was ill, so Dr. Murphy called in his attorney, Judge Geo. W. Brown. Again we started gathering information. We got track of some fifty men, more or less, who had secured certificates since the issuing of the injunction. These were distributed as follows: Pennsylvania, 8; Indian Territory, 1; Florida, 1; Bermuda, 1; West Virginia, 3; Ohio, 6; Alabama, 2; Indiana, 2; Michigan, 1; Tennessee, 1; California, 1; Missouri, 4; New York, 2; Kansas, 3; Kentucky, 2; Oklahoma, 1; Oregon, 1; Maine, 1; North Dakota, 1; Iowa, 1; Louisiana, 3; South Carolina, 1; Maryland, 1; California, 1; Texas, 2.

Men were sent out gathering affidavits from these purchasers. On the strength of these affidavits and accompanying certificates, Wood was brought into court.

The main defense centered around two points. The first was that Dr. Murphy's proper action was for libel, and that this court could not enjoin a libel. If you know that a man has been and still is libeling you, you can sue him for damages. but you can not enjoin him. The distinction made by Judge Holdom between a libel and a libelous action that is resulting in fraud is made clear to any layman.

The second was that no man can be restrained from using an uncopyrighted picture. Around most schools and hospitals pictures of physicians, clinics, etc., are usually on sale. If not copyrighted, any of these can be used to embellish anything, with this limitation, says Judge Holdom, that such use is improper if this use can be interpreted as meaning that anybody therein is endorsing or is in any way responsible for the institution making use of the picture.

As to the question of willfulness, Judge Holdom cited their use of the golden rule—the claim to effect Christian and humanitarian cure through the use of all means known to skilled physicians and surgeons, aided by magnetic and mental healers, etc., and their lack of consistency therewith; the misstatements embodied in a letter sent out after the injunction issued—but this is better read at first hand.

DECISION OF JUDGE HOLDOM.—(ORALLY.)

Murphy vs. Christian Hospital, N. News Wood, et al.

Proceeding for contempt for violation of injunctional order.

The environment of this case is somewhat peculiar. An institution known as the "Chicago Store" was first incorporated with a quarter of a million dollars of capital stock, upon its face, quite a business enterprise. Thereafter the corporate name was changed to "The Christian Medical Dispensary and Humane Hospital;" and then, on June 23, 1902, the latter name was changed to the "Christian Hospital."

We find that the "Christian Hospital," according to its designation in its literature, adopted as its beacon light the golden rule, "Do unto others as you would have others do unto you;" but from the nature of its peculiar methods, and the inducements held out to the unsophisticated and confiding doctors in the rural districts, it appeared in fact to conduct its affairs by the "David Harum" golden rule: "To do others before they have a chance to do you."

It is not necessary for me to pass upon the professional ethical condition which environed Dr. Wood and the "Christian Hospital," or his assistants, but the evidence shows that an eminent surgeon of this community, Dr. John B. Murphy, without his knowledge or consent, was subjected to the mortification of having his name, in facsimile of his signature, with his degrees following his name, together with a photograph of himself apparently about to engage in the performance of a surgical operation in a clinic, attached to the so-called certificate of membership in the "Christian Hospital."

Some criticism has been made of Dr. Murphy because he did not at once repudiate the action of Dr. Wood in connecting him, without warrant, with the "Christian Hospital." The letter of May 12, 1903, was the first intimation Dr. Murphy had of the liberties which had been taken with his name and professional standing. At the same time, Dr. Murphy received a very scathing letter from a Dallas, Texas, physician, which was inspired by the receipt of Dr. Wood's "Christian Hospital" literature. It was a very just and righteous expression of that doctor's indignation at Dr. Murphy for having, as it appeared to him from the literature received, deserted that high pedestal which he had theretofore occupied among his brethren in the medical profession, and stooped to connect himself in that way with this "Christian Hospital," which made propositions so unethical in its literature in an attempt to induce these rural doctors to become members of the hospital staff and receive the certificates which it offered for sale on a rising scale of from $5 to $25. When Dr. Murphy was confronted with what Dr. Wood had so audaciously done, and the unheard-of liberties he had taken with his name, it is not doing any violence to presume that Dr. Murphy was impressed with the utter futility of any attempt to do anything with a person of Wood's character, to head off further evil consequences to himself flowing from that which Dr. Wood had so unwarrantably done; and it is not at all surprising that instead of approaching Dr. Wood, he appealed at once to his lawyer to appeal to the courts to prevent further trouble for himself and his good name, and to prevent the sick and physically infirm from being further deceived through the alluring literature of Dr. Wood, or to entrust themselves to the so-called "Christian Hospital." It is apparent and self-evident from the facts in evidence that Dr. Wood had not connected with him or the Christian Hospital surgeons or physicians of the standing of Dr. Murphy, or any of the other gentlemen, whose names are so well known in medicine and whose pictures appear with Dr. Murphy in the clinic portrayed upon the certificates in evidence. It follows, therefore, that Dr. Murphy is excused and exonerated from any obligation to appeal to Dr. Wood before he filed this bill. The law requires no one to do a useless act before appealing to the law to right a wrong. I have no doubt that in the circumstances of this case, this court can give the relief that is prayed here, so far as to prevent the issuing of certificates with the name of Dr. Murphy, and in connection with it the picture of him about to engage in an operation in a clinic. However, the picture not being copyrighted, and having been given to the world free, any one may use it, but no one may, however, use it in connection with Dr. Murphy's name, so that the public may be deceived, defrauded or misled, and it is part of the province of a court of equity to prevent such frauds from being perpetuated.

Even assuming that this bill may not be sufficiently verified under the statute, still that would not make void the injunctional order, notwithstanding this court might, on proper application, dissolve the injunction. The court having jurisdiction of the parties and the subject matter, it is immaterial, howsoever erroneous the injunctional order may be; while it is in force, it must be obeyed, and he who willfully disregards it must pay the penalty of such rash and unlawful conduct.

What I may now say in relation to the evidential facts of this case is simply for the purpose of seeing where credence should be given, and who and what statements, if any, should be discredited, and in ascertaining the truth.

It is admitted that the first time Dr. Murphy knew of the unlawful use of his name was through the letter of Dr. Wood of May 12, 1903; that prior thereto Wood had no personal communication whatever with Dr. Murphy, nor was there any relationship between them, medically or otherwise. There is no evidence tending to show that Dr. Wood had any business, in any way, with Dr. Murphy, or that they operated together surgically at any time or place; or that Dr. Murphy was ever at the Christian Hospital, or even had a speaking acquaintance with Dr. Wood; so that no relationship existed between them which could, by the most liberal construction, lead Dr. Wood to the conclusion that he was at liberty, or might reasonably presume to take the liberty, to use Dr. Murphy's name and reputation in connection with the Christian Hospital as he did.

Now, Dr. Wood claims that the only authority for his actions rests on the statement of one Dr. Arthur C. Probert that Dr. Murphy had told him that his name might be so used. Probert appears as the vice-president of the Christian Hospital. Is such statement alleged to have been made by Probert borne out by the proofs? In that letter of May 12, Wood did not say anything about any arrangement or understanding with Dr. Probert. Wood simply told him in this letter to Murphy, that the Board of Directors had elected him, Murphy, to that position, and wanted him to accept of it in writing. There was not anything said in that letter, or at any other time, except upon this hearing, about Dr. Probert.

Now, Dr. Probert seems to be a mythical personage. He appears as vice-president of the Christian Hospital, and if he does exist——about which there is room for much doubt—he certainly must be, if he is entitled to the long string of degrees appearing after his name from regular collegiate institutions, a very learned gentleman; and a gentleman of so much learning as these degrees tend to indicate, would naturally be known, not only to many institutions, but to men of scholarly attainments and of high professional standing in this community, and he certainly could not be lost without creating considerable public notoriety. If Dr. Probert is not a myth, it is strange indeed that he has not been heard from; that his affidavit has not been tendered here, or that he has not come into court in person and by his testimony justify Dr. Wood in the use at least of Dr. Murphy's name. We do not hear from Dr. Probert at all, and now Dr. Wood disclaims any knowledge as to his whereabouts; neither does he vouchsafe any information as to the time or place where he last knew of him, or on what pretense he left this jurisdiction. The position of Dr. Wood is untenable; his representations in relation thereto glaringly false; his contentions are bald and shallow pretenses, which lack even the semblance of verity.

Has Dr. Wood or the Christian Hospital violated, willfully, the injunction of this court? Has Dr. Wood done any act in an endeavor to disclaim the right to do what he has done? To disclaim the verity of that which he has held out to these unsuspecting and confiding physicians all over this country? Not at all. Did he, by one word or insinuation, intimate to those gentlemen that Dr. John B. Murphy had never been connected with the Christian Hospital, or with him, and that the use of Murphy's name was absolutely and entirely unwarranted, and that he had presumed, without authority from Murphy, that he would be glad to be connected with the Christian Hospital, and therefore assumed to use his name? Not a word of truthful exposition escaped him. The only interpretation of which Wood's correspondence is susceptible, is, that through some disagreement between himself and Dr. Murphy, some disagreement that had arisen after and during the time of his assumed connection with the Christian Hospital, their relationship had been discontinued, and that in the future Dr. Murphy would cease to be what he had been to the Christian Hospital in the past.

I am unable to discover from these letters any willingness or desire on the part of Dr. Wood to either right the wrong he had done or to obey the injunction of this court. It does not appear from his actions that he was endeavoring to comply with or obey the injunction of the court, but that he was in fact endeavoring, in his own way, to evade the effect of that injunction, to evade the effect of it upon the persons to whom he wrote, by concealing from them the fact that this court had enjoined him from using the name of Dr. Murphy because he had assumed so to do, without warrant, and against law and right. I thoroughly agree with what Judge Brown has in effect said, viz.: that if there was no evidence in this record other than the letters which Wood wrote to Haynes and Clifford and those various other country medical men, that they would be sufficient in themselves to at least show the intentional and willful endeavor to evade the effect of this injunction. Dr. Wood was, by these letters, trying to induce the rural physicians to say that Dr. Murphy's name was not the magnet which drew them to his institution. It is self evident they were induced to join the Christian Hospital staff by the false representations and inducements held out by Dr. Wood, for it is self-evident the Christian Hospital, being very young, it had a reputation to establish, and nobody realized that probably more than Dr. Wood did, and it may well be, that such knowledge was one of the influences affecting his actions, and which prompted him to make this unwarranted use of Dr. Murphy's name; and there is abundant evidence here that certificates have been issued since the service of this injunction of June 3, 1903, upon Wood and the hospital, with the name of Dr. Murphy and with his picture in the surgical clinic, and I am of the opinion that the correspondence with Clifford and others was in effect a reissue of the certificates then in their hands. I am free to say that what appears to have been an attempt to obliterate the name of Dr. Murphy was simply a subterfuge, and it is too plain to admit of denial that the name of Dr. Murphy was more apparent after the attempted obliteration than it really was before, because the mark being so lightly drawn through it, instead of obliterating it, simply accentuated and attracted more particular attention to Dr. Murphy's name than if the mark had not been placed there, and Dr. Wood can not be excused because he claims to have delegated the task of erasing Dr. Murphys name to another.

Aside from Dr. Murphy, the public have a right to be protected, and if these things can be done, it seems to me that the law would be lacking in one of its great attributes if it was impotent to remedy so great a wrong. Can a man's professional reputation be slandered and outraged and the law afford no adequate relief? If there be a remedy—and surely there is—and the injury be irreparable at common law, is a court of equity without power to grant relief? I doubt not its beneficent arm will be outstretched to stay the hand that smites and shield the object of the assault from further harm. I base this conclusion on the law on broader grounds than taken by counsel for respondents—that is aside from the invasion of the rights of Dr. Murphy—on the broad humanitarian ground that the sick and afflicted will be protected from being deceived and misled, and perchance be lured to their death by the false representations that at the Christian Hospital they will find, not Dr. Wood, but Dr. Murphy, and other men of his caliber to minister to their diseased and afflicted bodies. Such charlatans as Dr. Wood, and such conglomerate affiliation of quackery and baser schools of medicine to be found in practice at the Christian Hospital, will not only be condemned, but restrained by law from pirating on the public when fraud and deceit are the alluring factors—and the court is asked to do so.

Now, Dr. Wood had no business to ignore this injunction. He had no business to go on in his own way and do just as he might see fit. The least he could have done after he was served with this injunctional order, if he desired to proceed further in the matter with the business in which he had started, was to have consulted a lawyer, and it is not to his credit that he neither saw a lawyer nor came to the court asking to have this injunction dissolved. But without the advice of counsel, he went his own way and kept along in the same illegal path, with only a subterfuge of a pretense to comply with the mandate of this court, and inserted the name of Dr. Somers as a pretended substitute for that of Dr. Murphy, while so far as can be seen, Somer's name appeared to be added, not Murphy's taken out.

I am more embarrassed in relation to the punishment which should be meted out to Dr. Wood and the Christian Hospital than I am about the other branch of the case. I am inclined to think, from what appears on this record, Dr. Wood is a dangerous man to any community. He is not free from suspicion, and a grave one, that the manner in which the name of Dr. Murphy appears is in law a forgery. A criminal act. It purports to be Dr. Murphy's signature, but I am not here to punish him for forging Dr. Murphy's name, but I may take *into consideration* the moral turpitude of Dr. Wood in determining the degree of punishment which should be meted out to him for his willful violation of the injunctional order.

I will fine the Christian Hospital two hundred and fifty ($250) dollars, and I will fine Dr. Wood one hundred ($100) dollars, and sentence him to ten days' imprisonment in the county jail, and it is so ordered.

We will not close without some personal references. Dr. Murphy has expended a large sum of money in accumulating evidence needed to rid himself, the profession, and the people from this menace. Our thanks are also due to Drs. Deaver and Taylor of Philadelphia, Wiggins of New York, McCormack and Wathen of Kentucky, Dinnen and Bruggeman of Indiana, Blanchard of Wisconsin, Sheldon of Iowa, beside a large number of others to whom we are just as grateful. Signed, W. A. Evans, H. A. Moyer, C. S. Bacon, Medicolegal Committee, Chicago Medical Society.

Treatment of Hernia.—Dr. J. M. Banister of the First Reserve Hospital, Manila, P. I., calls our attention to two errors which occurred in his manuscript and which also appeared in the publication of the article, "The Radical Treatment of Nonstrangulated Inguinal Hernia from the Standpoint of the Modern Surgeon," in The Journal, Oct. 22, 1904. On page 1226, in the remarks on Kocher's operation, the sentence should read: " . . . owing to the proximity of such important structures as the *external*" (not internal, as printed) "iliac vessels . . . ." In the last paragraph on the same page the name of Dr. Dawbarn of New York is erroneously given as "Dr. Newbern."

The Books of the Year 1904.—Those who were *interested* in the summary of the new books published during the year 1904 which we gave in The Journal, January 7, page 53, will be further interested in the following from the *Medical Book News*. Its summary, unlike our own, includes new editions and republications. "Were any reader of this magazine, possessing $1,489.58, desirous of expending it in the purchase of new books for his library, every standard American and English work on medicine in each of its various branches, and on dentistry, pharmacy, chemistry and the allied sciences, published during the current year, could be included. This would mean the acquisition of 575 titles, containing 193,094 pages, with 40,689 illustrations, many in colors. Reducing the different values to a like basis, the cost of each octavo book of 335 pages and 70 illustrations would cost an even $2.59." In this connection we may remark that the list which we published was so nearly complete that our attention has been called to only one book as having been omitted from our list. That one is "Semeiology and Diagnosis of Diseases of Children." N. Filatov and Frank B. Earle, 2 vol., $7, Cleveland Press, Ogden avenue and Lincoln street, Chicago.

State Boards of Registration.

COMING EXAMINATIONS.

New Hampshire State Boards, University Club, Concord, February 1-2. Regent, Henry C. Morrison, Concord.

Board of Medical Registration for Vermont, Burlington, February 7, 8 and 9. W. Scott Nay, M.D., secretary, Underhill.

Nebraska State Board of Health, State House, Lincoln, February 8-9. George H. Brash, M.D., secretary, Beatrice.

Kansas State Board of Medical Registration and Examination, Topeka, February 14-15. Secretary, G. F. Johnston, M.D., Lakin.

Officers of Ohio Board.—The Ohio State Board of Medical Registration and Examination organized January 3 for the year by the election of the following officers: President, S. B. McGarvan, Cadiz; vice-president, H. H. Baxter, Cleveland; secretary, Frank Winders, Columbus; treasurer, S. M. Sherman, Columbus.

West Virginia 1904 Reports.—Dr. H. A. Barber, secretary of the State Board of Health of West Virginia, reports the examinations held at Clarksburg, Charleston and Wheeling, in April, July and November, respectively. At the oral and written examination, held at Charleston, April 12-14, the number of subjects examined in at each *examination* was 9; total number of questions asked, 120, and percentage required to pass, 75. The total number examined was 63, 33 of whom were undergraduates. Of the graduates 28 passed and 2 failed, and of the undergraduates 28 passed and 5 failed.

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U. S. Army, week ending Jan. 14, 1905:

Stiles, Henry R., asst.-surgeon, ordered to report to Major William H. Arthur, surgeon, president examining board, Jan. 17, 1905, Washington, D. C., for examination for promotion.

Reilly, John J., asst.-surgeon, left Jackson Barracks, Louisiana, en route to Army and Navy General Hospital, Hot Springs, Ark., for treatment.

Ebert, R. G., surgeon, left Vancouver Barracks, Washington, with artillery en route to Fort D. A. Russell, Wyoming.

Morse, A. W., asst.-surgeon, ordered to accompany field artillery to San Francisco and then return to post.

Chidester, W. C., asst.-surgeon, left Fort Lawton, Washington, on ten days' leave of absence.

Coffey, Albion McD., contract surgeon, ordered from Joplin, Mo., to Fort Warden, Washington, for duty.

Porter, Elias H., contract surgeon, granted an extension of his leave of absence to Jan. 29, 1905

Casaday, George H., dental surgeon, granted leave of absence for three months, with permission to visit the United States.

Freeman, Charles E., contract surgeon, granted leave of absence to include Jan. 31, 1905.

Foulkes, Bruce, contract surgeon, arrived at San Francisco January 2 for one month's leave of absence.

Truax, Jesse P., contract surgeon, left Fort Ward, Washington, January 5 for temporary duty at Fort Lawton, Washington.

Sparremberger, Frederick H., contract surgeon, left Fort Mott, New Jersey, January 7 on leave of absence for ten days.

Treuholtz, Clarence A., contract surgeon, returned to duty at the Army General Hospital, Fort Bayard, New Mexico, January 5 from leave of absence.

Wall, Francis M., contract surgeon, returned to duty at Fort Oglethorp, Georgia, January 9 from leave of absence.

McCall, James H., contract surgeon, left Fort Moultrie, South Carolina, January 10 for temporary duty at Key West Barracks, Florida.

Burr, Rollin T., contract surgeon, returned to duty January 10 at Fort Rodman, Mass., from leave of absence.

Hayes, Melville A., contract surgeon, left Washington, D. C., January 11 for duty at Vancouver Barracks, Washington.

Lemmon, Robert, contract surgeon, arrived, January 11, at Fort Terry, N. Y., for temporary duty.

Oliver, Robert T., examining and supervising dental surgeon, arrived at West Point, N. Y., January 14 for duty.

Navy Changes.

Changes in the medical corps, U. S. Navy, for the week ending Jan. 14, 1905:

Young, R. M., asst.-surgeon, resignation accepted to take effect Jan. 31, 1905.

Taylor, J. S., P. A. surgeon, detached from the *Relief* and ordered to the *Ohio*.

Public Health and Marine-Hospital Service.

List of changes of station and duties of commissioned and non-commissioned officers of the Public Health and Marine-Hospital Service for the seven days ending Jan. 11, 1905:

White, J. H., surgeon, granted leave of absence for six days from January 17.

Wertenbaker, C. F., surgeon, to report at Washington, D. C., for special temporary duty.

Blue, Rupert, P. A. surgeon, detailed as inspector of unserviceable property at the Marine Hospital, San Francisco.

Fricks, L. D., P. A. surgeon, relieved from duty at LaGuayra, Venezuela, and directed to proceed to New York and report arrival by wire.

Korn, W. A., P. A., surgeon, Bureau letter of Dec. 27, 1904, granting leave of absence for seven days, amended so that said leave shall be for four days only.

Atiles, Pedro del Vallo, A. A. surgeon, granted leave of absence for seven days from Dec. 26, 1904, under Paragraph 210 of the Regulations.

Edwards, J. W., A. A. surgeon, granted leave of absence for twelve days from Dec. 20, 1904, and three days from Jan. 1, 1905.

Jackson, J. M., Jr., A. A. surgeon, Department letter of Dec. 8, 1904, amended so as to grant leave of absence for nineteen days instead of thirty days from Nov. 26, 1904.

Tuttle, Jay, A. A. surgeon, granted leave of absence for thirty days from January 9.

Wetmore, W. O., A. A. surgeon, granted leave of absence for ten days from January 4.

Stearns, W. L., pharmacist, to proceed to Washington, D. C., for special temporary duty.

Gibson, F. L., pharmacist, leave of absence granted for thirty days from Jan. 1, 1905, amended to read ten days from Jan. 1, 1905. Relieved from duty at Honolulu, T. H., and directed to proceed to San Francisco and report to medical officer in command for duty and assignment to quarters, relieving Pharmacist Chas. Slough.

Slough, Chas., pharmacist, on being relieved from duty at San Francisco by Pharmacist F. L. Gibson, to proceed to Honolulu, T. H., and report to chief quarantine officer for assignment to duty.

CASUALTY

Hanrath, F. R., pharmacist, died at Cleveland, Ohio, Jan. 7, 1905.

Health Reports.

The following cases of smallpox, yellow fever, cholera and plague have been reported to the Surgeon General, Public Health and Marine-Hospital Service, during the week ended Jan. 13, 1905:

SMALLPOX—UNITED STATES.

District of Columbia: Washington, Jan. 1-7, 2 cases.

Illinois: Chicago, Jan. 1-7, 16 cases; Peoria, Dec. 1-31, 7 cases.

Louisiana: New Orleans, Jan. 1-7, 5 cases, 3 imported.

Massachusetts: Jan. 1-7, Everett, 2 cases; Hyde Park, 1 case.

Missouri: St. Louis, Dec. 25-Jan. 7, 35 cases, 6 deaths.

New Jersey: Camden, Jan. 1-7, 1 case.

Ohio: Cincinnati, Jan. 1-7, 7 cases.

South Carolina: Jan. 1-7, Charleston, 3 cases; Greenville, 6 cases, 1 death.

Tennessee: Nashville, Jan. 1-7, 6 cases.

Wisconsin: Milwaukee, Jan. 1-7, 3 cases.

SMALLPOX—FOREIGN.

Austria-Hungary: Prague, Dec. 11-24, 24 cases.

Brazil: Bahia, Nov. 29-Dec. 10, 27 cases, 1 death; Rio de Janeiro, Nov. 28-Dec. 4, 296 cases, 108 deaths.

Belgium: Brussels, Dec. 18-24, 1 death.

China: Shanghai, Nov. 13-26, 71 deaths.

France: Paris, Dec. 18 24, 17 cases.

Great Britain: Dec. 18-24, London, 9 cases; Newcastle-on-Tyne, 7 cases; Nottingham, 3 cases; South Shields, 3 cases.

India: Bombay, Dec. 7-13, 19 deaths.

Panama: Dec. 26-Jan. 1, Colon, 1 case; Panama, 1 case.

Russia: Moscow, Dec. 11-17, 7 cases; St. Petersburg, Dec. 18-24, 6 cases, 5 deaths.

Turkey: Constantinople, Dec. 19-25, 8 deaths.

YELLOW FEVER—UNITED STATES.

Texas: Galveston, Dec. 31, 2 cases from S. S. *Horatio* from Para, via Barbados.

YELLOW FEVER—FOREIGN.

Brazil: Rio de Janeiro, Nov. 28-Dec. 11, 2 cases, 1 death.

Cuba: Habana, Jan. 6, 3 cases, 2 from Austrian vessel *Dora*, from La Guaira and Colon.

Mexico: Dec. 25-31, Coatzacoalcos, 1 case; Juchitan, 1 case; Vera Cruz, 1 case, 1 death.

Panama: Panama, Dec. 25-31, 2 cases.

CHOLERA.

India: Bombay, Dec. 7-13, 2 deaths; Calcutta, Dec. 4-10, 72 deaths.

Russian Empire: Nov. 23-29, Astrachan District, 6 cases; Samara District, 162 cases; Saratov, 40 cases, 19 deaths; Trans-Caspian Territory and Central Asia, Serachs, 27 cases, 20 deaths; Jelisavetpol District, Nov. 22-26, 32 cases · .. Caucasia, Baku, Nov. 14-23, 29 cases, 10 deaths; Batum, Dec. 1-7, 3 cases; Erivan, Nov. 23-29, 1,933 cases, 661 deaths.

PLAGUE.

Arabia: Dec. 1-16, Crater, 47 cases, 47 deaths; Maalla, 2 cases, 2 deaths; Hedjuff (hospitals), 2 cases, 2 deaths; Tawahi, 1 case, 1 death; Shaikh Othman, 3 cases, 4 deaths.

Egypt: Port Said, Dec. 3-10, 1 case, 1 death; Tukh District, Nov. 27-Dec. 10, 3 cases, 3 deaths.

Great Britain: London, Nov. 30, 1 case, from S. S. *Weybridge* from the Rio de la Plata.

India: Bombay, Dec. 7-13, 72 deaths; Calcutta, Dec. 4-10, 12 deaths; Karachi, Dec. 5-11, 27 cases, 22 deaths.

Straits Settlements: Singapore, Dec. 20-26, 1 case, 1 death.

Society Proceedings.

WESTERN SURGICAL AND GYNECOLOGICAL ASSOCIATION.

Fourteenth Annual Meeting, held in Milwaukee, Wis., Dec. 28-29, 1904.

(Concluded from page 153.)

The Manufacture and Use of Tin Splints.

Dr. Arthur T. Mann, Minneapolis, made a plea for the general utility of tin splints. He pointed out the simple equipment necessary to make them; also the ease of making the splints and patterns for them. He described several tin appliances which are useful, among them a device for regaining flexion and extension of the elbow joint after fractures and dislocations. This article will be published in The Journal later.

Syncytioma Malignum.

Dr. H. C. Crowell, Kansas City, Mo., reported a case and gave a detailed pathologic report of the specimen.

Dr. Archibald MacLaren reported a case of what he had supposed to be a soft edematous fibroid, but after operation the case proved to be one of syncytioma malignum.

Fractures of the Tarsal Bones.

Dr. Daniel N. Eisendrath, Chicago, called attention to the surgical anatomy of these bones and to the mechanism of fractures. He reported six cases on which he had operated, and presented the following conclusions:

(1) The astragalus and os calcis bear the entire weight of the body. (2) They are most frequently broken in falls from a height directly on the feet (compression variety), or by tearing off of a portion of one of the bones, either when the heel is fixed or sudden supination or pronation, or in forcible dorsal flexion of the foot. (3) Early diagnosis, on account of the danger of sepsis from secondary skin necrosis, is of great importance. (4) If there is no displacement of fragments, treat the case by a cast for six weeks, with early massage. If displacement should threaten necrosis of skin, convert into an open fracture, and either remove the fragment or suture it.

Ptosis of the Abdominal and Pelvic Organs.

Dr. R. C. Coffee, Portland, Ore., drew the following conclusions:

(1) The peritoneum is attached firmly not only to the diaphragm, but loosely by all its outer surface to the abdominal and pelvic walls by means of loose connective tissue, which allows it to move freely, but holds it always in contact. This connective tissue is much increased around the attachment of the supports of each organ. The irritation underneath and back of the peritoneum is followed by an exudate which fixes it immovably to the abdominal wall. This exudate is soon displaced by an increase of normal connective tissue sufficient to meet the demands. The peritoneum itself is but slightly elastic, its seeming elasticity being due to the elasticity of the subperitoneal connective tissue. (2) Two peritoneal surfaces brought together and held firmly in an aseptic state blend and become one membrane. If suppuration or other disturbance occurs, blending does not take place, but inflammatory adhesions are formed. The former is permanent, while the latter is transitory and will be absorbed generally. This differentiation is all-important. (3) The uterus is suspended entirely by its peritoneum and connective tissue. (4) The so-called true ligaments are not such, but muscles, and therefore perform the same function as all other muscular fibers in the animal organism, which is intermittent contraction, but never constant action. Their function is to sustain the normal poise or balance of the uterus during the changing positions of the body. (5) Whatever may be the cause, the condition existing is a stretching of either or both the peritoneum and connective tissue. The condition may be local or general, and may involve the support of one, more than one, or all the abdominal and pelvic organs. (6) Treatment in a general way will be the shortening of the peritoneum at the points at fault by some method of plication and blending, or by bringing the peritoneum back to its normal contact with the abdominal wall. (7) The method (he described) for suspending the liver is, I believe, almost ideal theoretically, and so far in my experience clinically and experimentally, in that it shortens the normal suspensory ligament, and supplements it by extending the ligament to one or both lobes by blending of peritoneum. (8) None of the operations for gastroptosis so far is theoretically or practically ideal for all cases. The hammock operation, stitching the omentum to the abdominal wall, is best suited to those cases due to adhesions holding the stomach out of place by its omentum, in which the condition accompanies operations on the lower abdomen or pelvis only. No discomfort has been observed by any of my patients. Posterior gastroenterostomy is the best operation for those cases due to dilation or pyloric obstruction of any kind, and is all that is necessary, as it is held by its attachment high up and well back to the transverse meso-colon.

Appendicitis in Women.

Dr. Archibald MacLaren, St. Paul, Minn., stated that the only safe advice to both the patient and the physician is that the appendix should be removed in the early hours of every acute attack, and especially in the first attacks, when the symptoms last six hours. On the other hand, he does not believe that every case of appendicitis should be operated on as soon as the diagnosis is made, because the surgeon frequently does not see these cases until from the third to the sixth day. The favorable time has now passed, and some of these cases are in such a bad condition that the operation itself may be enough to take away the only remaining chance of recovery. He has done 422 appendectomies. In the first 241 there were 72 suppurative cases. Of these 42 were men and 30 were women. During the same time he removed appendices showing chronic inflammatory changes 153 times in women, and only 17 times in men. He does not believe that chronic appendicitis is as frequent in the male as in the female, but it probably is not twice as frequent in the latter sex. It is, he believes, only a curious accident that he has seen proportionately so many acute cases and so very few chronic cases in men.

Management of Hospitals in Large Cities.

Dr. D. S. Fairchild, Des Moines, Iowa, said that the problems involved in the management of hospitals in the smaller cities are difficult and complicated, growing out of two important facts: (1) The supposed self-interest of individual members of the medical profession; (2) the lack of experience and knowledge on the part of boards of management. Public hospitals are generally of three kinds, as determined by the auspices under which they are organized and in part supported: (a) Hospitals under the auspices of some church; (b) hospitals under the auspices of some society, and (c) city hospitals supported by public taxation. The method of appointment of physicians to hospitals is liable to abuse only when piety or church zeal is mistaken for competency. Dr. Fairchild discussed the management of hospitals at great length.

Arthrotomy.

Dr. E. Wyllys Andrews, Chicago, described a new method for treating old dislocations of the shoulder joint, and after mentioning the steps of the procedure at some length, he presented the following conclusions:

(1) It must be considered established that great force is never justifiable in old shoulder dislocations. (2) Few cases can be left unreduced, on account of pain and pressure symptoms, on the brachial plexus. (3) Resection is satisfactory, but not ideal or wholly safe. (4) Arthrotomy by the old incisions is tedious, and has never been widely practiced. (5) Arthrotomy by the author's method is simplified and made quicker and safe. It would possibly be as safe as resection, and much more ideal in results.

Curettage and Puerperal Sepsis.

Dr. C. E. Ruth, Keokuk, Iowa, discussed the etiology of puerperal sepsis, the kinds of infection, prevention and dangers, and then spoke of curettage, drainage and hysterectomy in such cases.

Our Duty to the United States Army and to Its Medical Corps.

Dr. Donald Macrae, Jr., Council Bluffs, Iowa, pointed out the importance of having a more efficient medical corps in the United States Army.

A resolution was introduced and unanimously adopted, respectfully petitioning President Roosevelt to direct the military authorities to provide a field medical organization for our army at least equal in all respects to the best that exists in any army, and which will meet the approval of military sanitarians generally, to the end that the sick and wounded in future wars may receive adequate care and attention.

The secretary was instructed to forward a copy of this resolution to President Roosevelt at once.

Dr. G. G. Eitel, Minneapolis, read a paper on "Removal of the Covering of the Ovaries in Ovarian Dysmenorrhea," which is abstracted in The Journal, page 247.

The Diagnosis of Early Tubal Pregnancy.

Dr. William E. Ground, Superior, Wis., bases his deductions on the histories and the gross appearance of the uterus and appendages at the time of operation in 28 cases. He is firmly convinced that ample pathology was present to cause the arrest of the fecundated ovum in the tube. Five of his cases were in primiparæ, who gave a history of painful menstruation and leucorrhea. Thirteen cases gave a history of sterility of three or more years' duration. The remaining 12 cases occurred in parous women, who had borne children or had been pregnant in less than three years. Many of these women gave unmistakable evidence of pre-existing pelvic disease. One primipara had been married three years, one five and another eleven years before tubal conception occurred. Two cases occurred in unmarried women, one of whom had had a criminal abortion. Complications arose necessitating abdominal section. An unruptured tube containing a six weeks' fetus was found. Another case, known to have had chronic appendicitis, was taken with sudden, severe pain in the right lower abdomen, followed by considerable shock, but she soon rallied. Menstrual irregularities were denied. Tenderness was present rather low in the iliac fossa. The uterus was enlarged, and a slight bloody discharge came from the vagina. There was an ill-defined tumor to the right of the uterus. The abdomen was opened and found to contain blood clots and bloody serum. The right tube was ruptured on its dorsum at about the middle, but the fetus was still in the tube. Chronic appendicitis was also present, and the appendix was removed. Two cases had small fibroids, and one had an ovarian cyst as large as an orange on the opposite side.

CLEVELAND ACADEMY OF MEDICINE.

Meeting of the Clinical and Pathologic Section, held Dec. 2, 1904.

Dr. C. A. Hamann in the Chair.

Hereditary Muscular Dystrophy.

Dr. Walter G. Stern presented cases of muscular dystrophy of the hereditary type occurring in the same family, girls of 15 and 12. They showed marked shortening of the tendo Achilles, causing them to walk on their tiptoes. The great-grandmother walked on her toes, the grandmother had spasms of the calf, and the grand aunt had contractions of the trunk and extremities. Two uncles were also affected, one so badly that he had to walk on his hands and knees. The father of the children had severe pes equinus. The muscles of the calf were wasted and contracted, and the muscles of the trunk so affected that when he picked up objects he was obliged to crawl up his thighs to regain his equilibrium. The family consists of three daughters and two sons. One of the sons died and before death was so afflicted that he had to crawl. The other son is only 7 and shows, as yet, no signs of the disease. The oldest of the girls was very much wasted, the contractions being almost general, the younger ones showing lesser grades. The pes equinus was so marked in the second daughter that tenotomy had been resorted to, with improvement in her condition.

Suppurative Pericarditis and Chylous Ascites.

Dr. C. F. Hoover cited a case in which the triangular area of dullness in the back was absent and discussed the differential diagnosis of such cases from pneumonia and other conditions. He also presented the notes of a case of true chylous ascites, in which chemical analysis showed the presence of actual chyle, thus distinguishing it from the many cases of ascites in which the fluid is chyliform, but contains no chyle, being due rather to other conditions, such as malignant growths not involving the lacteals. The two kinds of fluid may closely resemble each other, but the chemical analysis will always differentiate. The patient is still alive and has a mass centrally placed in the abdominal cavity, but so far no diagnosis of the lesion has been made.

Typhoid Necrosis of Pharynx.

Dr. F. C. Herrick described a case in which a large area of necrosis with extensive sloughing followed a case of typhoid, the ulceration being so deep as to expose the bone. The case recovered under appropriate treatment.

BOSTON MEDICAL LIBRARY ASSOCIATION.

Meeting of the Surgical Section, held Nov. 30, 1904.

Dr. F. B. Harrington in the Chair.

Enteroptosis and Nephroptosis.

Dr. M. P. Smithwick emphasized the importance of considering ptosis of the viscera in nephroptosis. In 68 cases studied there was ptosis of the right kidney in all, and in 20 per cent. of the left as well. In 62 per cent. the stomach was depressed; in 7 per cent. the liver, and in 80 per cent. of the 34 cases examined for it there was displacement of the uterus, usually extreme retroversion. Nearly all had neuropathic tendencies, and he believes that this chances to be the point of least resistance. Many of these showed no symptoms whatever of the ptosis. In no case was there a disturbance of the renal function, and in only one case was there any dragging sensation.

Dr. W. H. Smith gave his experience in treatment with abdominal supporters. Unpadded abdominal bands proved failures except in cases associated with gastroptosis. But an accurately fitted corset-like belt, applied while the patient is lying down, will hold the intestines up against the liver and prevent the kidney from falling. Intelligent co-operation on the part of the patient and a proper fit are indispensable.

Dr. F. G. Balch reported the actual results at the Massachusetts General Hospital following operative treatment from 1890 to 1904. Of 92 cases treated 86 were females, 6 males; 61 married, 25 single; in 33 pregnancy was assigned by the patients as the starting point of her trouble and in 10 trauma. The patients remained in the hospital from 15 to 45 days, an average of 28 days. Seventeen had other operations done at the same time. Eight cases were found septic. Twenty-two had urinary symptoms before operation. Final results were ascertained in 41 cases. Twenty-eight were relieved, 13 not relieved. Balch considered operations of doubtful value in nervous cases and would try supporters first. Long rest and proper care are necessary for the success of the operation.

Dr. J. H. Crandon presented the records of the Boston City Hospital. During the last 10 years 17 cases were operated on. Their ages varied from 20 to 59 years. All were women. The trouble had lasted from five months to 13 years. Five patients reported themselves as cured, 1 better but not well, 2 have had a recurrence, and 2 were cured only after a subsequent operation for gallstones. No record was obtained in 7.

Dr. H. D. Chadwick said that two symptoms call for operation: first, a burning sensation along the ileo-hypogastric nerve, and second, distress and restlessness after going to bed. Apparatus adds to the discomfort. He has operated on 20 cases with but three failures. In two of these the symptoms continued, and the third did not stay fixed.

Dr. A. T. Cabot suggested that, perhaps, the vein of the right kidney being shorter than the artery is why it is occluded more quickly. This suggestion appeared to be borne out by three cases of profuse hematuria seen by him. Early operation is important; late cases are often not benefited. He advised fixation with an insoluble suture, such as silk, putting the stitches only through the capsule. He did not approve of Edebohls' method which, he believes, causes pain. The kidney must be fixed so that the liver can not press on it.

Dr. Paul Thorndike examined 272 women, selected at random, for floating kidney, and found it present in 112 cases. None of these women had any symptoms attributable to the ptosis. He advised care in choosing operative cases, but preferred operation to wearing a belt.

Dr. A. K. Stone said that some cases seem to have inherited the trouble. He has noted a great variety of symptoms. Even though a kidney can be felt it may not be the cause of the trouble. He operates only when the displacement is the cause of all the symptoms. He has had good results from the use of apparatus, but it must be fitted accurately.

Dr. W. B. Conant makes a lateral incision and uses absorbable sutures, but does not split the capsule. He enters the peritoneal cavity and explores all other organs, treating them, if necessary. He fastens the kidney on a shelf between the muscles. A truss may be useful if pressure is rightly directed.

Dr. R. C. Larrabee thought that these cases are usually neurasthenics and that they suffer from crises of pain. Ptosis of the kidney, he said, is a very common anomaly and rarely productive of any harm. A corset-like bandage may tide over an attack and thus obviate the necessity of an operation.

Dr. G. W. Gay approved of Osler's dictum, "If the patient does not know of the ptosis, do nothing."

Dr. F. B. Lund said ptosis of the kidney is usually a part of a general visceral ptosis. Operation is safe, but any abdominal support will give relief.

Dr. D. H. Craig said that a belt acts like a splint and that massage is necessary if the abdominal muscles are to fulfill their function.

Dr. C. P. Putnam has obtained good results from manual manipulation, the patient standing upright. Congestion is relieved and the pain ceases.

Travel Notes.

FOUR THOUSAND MILES THROUGH INDIA BY RAIL IN MIDSUMMER.

NICHOLAS SENN, M.D.

CHICAGO.

(Continued from page 65.)

INDIAN SUMMER CLIMATE.

The hot season in India begins with the month of April and is expected to end with the month of October. It is said that April and May are the hottest and that November, December and January are the coolest months of the year. On the way from Tuticorin to Madras the shade and night temperature rose to 98 F. and the temperature in the sun to 119 F. Soon after leaving Madras rain set in and continued without interruption until we reached Calcutta and during the first day I remained in that city. The atmosphere was saturated with humidity and added greatly to the discomforts and actual suffering from heat, although the temperature at night and in the shade did not exceed 98 F. The air was not disturbed by the slightest breeze, it was motionless, paralyzed, stifling. Breathing required an effort and the sweat poured from the surface even when at rest.

> " 'Heat, ma'am,' I said; 'it was so dreadful here that I found there was nothing left for it but to take off my flesh and sit in my bones.' "—Sydney Smith.

How often did I envy those natives, with their lithe, slender, fatless bodies and their long arms and legs and flexible joints. In squatting, the easiest resting position for these natives, the legs fold on themselves like a jackknife. The agony I experienced from a combination of humidity, heat, and the lazy, sleeping air during the two nights and days I spent in Calcutta would be difficult, yes, impossible, to describe; bathed in sweat, panting for breath, with only partial relief from ice and soda and from vigorous pulling of the bedroom punkah throughout the night, by men employed for that purpose.

A word concerning the punkah puller. Two men or two women, or one man and one woman are hired for the night, and they receive 8 cents each for their easy work and loss of sleep. One night I had two men at the ropes; about midnight the to and fro motions of the punkah became less and less and finally almost came to a standstill. I went to the door and found one of them sound asleep and the other barely awake. The slight jerks were directed by the spinal cord exclusively; the brain was sleeping. A few sharp words brought life to men and punkah.

I was made to comprehend by a trying experience the meaning of

> "A dem'd, damp, moist, unpleasant body."—Dickens.

I spent a whole forenoon in visiting the Calcutta Medical College and large government hospital connected with it, under the guidance of Major Drury, I.M.S., principal of the school. We inspected the laboratories, walked from ward to ward, climbed stairs innumerable and, although an attendant with an enormous fan accompanied us and gave us the full benefit of the useful article, I soon felt the sweat running in streams down my legs and into my shoes and, in spite of frequent wiping of face and neck, the collar soon wilted into a shapeless rag. It was then it occurred to me:

> "Ay, now am I in Arden; the more fool I.
> When I was at home I was in a good place, but
> travelers must be content."—Shakespeare.

For once I was glad when the visit was at an end and the courteous major took me to his private apartments, where a most luxurious breakfast was served and where my torturing thirst was quenched with ice and claret. As soon as we arrived in the room, the major suggested that I should make myself more comfortable by removing the coat. I did so most willingly and then discovered to what extent the clothing had become saturated by the profuse sweating. Judged by the clothing, and found near the Ganges, the suspicion would have been well founded that I had been rescued a few moments ago from drowning in the sacred river. Without rain and sweating the clothing would become moist from the excessive humidity of the atmosphere. What discomfort and annoyance this creates. Try under such circumstances to fetch in a hurry from the wet trousers pocket with a sweating hand a coin for a tip and you will find that the pocket becomes a veritable trap for the hand, which is with difficulty extricated without everting the pocket and scattering the coins.

It seemed to me strange that the temperature increased as I traveled north, but in leaving the coast the humidity gradually diminished, and in the interior the air was comparatively dry. The thermometer I carried with me registered 132 F.; on several occasions the mercury reached the maximum limit in the sun and would undoubtedly have gone higher had there been additional space. This high temperature was registered at Agra, Delhi and Jaipur. The night and shade temperature on the whole trip from Calcutta to Bombay ranged between 92 to 105 F. The Bombay weather was very much like that of Calcutta, rain and humidity, but the temperature was a little lower and occasional breezes diminished the sweating and relieved the intense sense of heat.

All through India the absence of a breeze made the heat distressing. Some days about 4 o'clock in the afternoon a slight agitation of the atmosphere would begin; enough to shake slightly the leaves of the omnipresent nim trees and would bring with it a decided relief, but even this slight attempt on the part of the atmosphere to counteract the effect of the burning sun was always of short duration. It was interesting to observe how the animals, wild and domestic, behaved during the hottest part of the day. The water buffalo is a great bather and he is not particular about the nature of the bath; if he has any preference, it is for the mud bath. In passing the many water and mud holes along the line of the railroad, I have often seen through the car window two long, flat, reclining horns and a pair of sleepy or closed eyes just above the level of the mud or water, and in looking closer might distinguish back of them the ridge of the spine, the balance of the body being completely immersed. The buffalo has three objects in view when he goes bathing:

To rid himself for the time being of pestering insects, to obtain relief from the intense heat and to obtain a soothing rest after his liberation from the hard, primitive yoke. Sometimes we saw a herd of these animals closely packed in a small pool or mud hole. It is a peaceable, tolerant animal, so that even when standing space is scarce, these animals of burden make room for each other without the slightest indication of selfishness. I fancy that the water buffalo prefers mud to water for his bath, for it leaves a thick layer of mud on the surface of his body, which soon dries into a crust, a further protection against flies and mosquitoes. The bullock, sheep and goats seek the shade of trees during the hottest part of the day, and if the trees are few and the animals numerous, every inch of it is made useful, and, as the shade moves, the family of animals shifts in the same direction to protect themselves against the scorching rays of the sun.

The proud peacock, so numerous all through India, but more especially in the eastern part, forgets for a time his vanity when the sun is in a position to send down on poor India its most scorching rays. He folds and hangs his gaudy tail and sneaks away into the shade of a clump of shrubs or cactus hedge and lowers his microcephalic head with half closed eyes in obedience to his majesty of the day. India swarms with turtle doves and the telegraph wires are their favorite perch. In many stretches of the country from one to a dozen of these tidy, innocent birds can be seen perched on a wire between two telegraph posts as the train rushes by. When the temperature rises to 130 F. and more, the wires become too hot for their tiny red feet and they are driven by the heat to find protection in the shade.

Man appears to possess the greatest resisting power against heat. The coolie, bareheaded or with a few pads of cotton cloth wrapped about his head in the form of a turban, can be seen at work any time of the day, no matter what the thermometer may say. From early morning until late at night he toils in the fields, plowing, sowing, harvesting, or dipping water, as the case may be, to earn his scanty livelihood. In many parts of India the month of September is the most trying one. My guide at Delhi called it the "sickness month," and informed me that during the month few escaped fever, which would last from one to several days. I presume a mild form of malaria.

The insects were not so troublesome as I expected At Jaipur the flies were numerous and aggressive. In the hotel at Calcutta I found my bed screened with mosquito bar. As the evening was extremely sultry and as I heard no mosquito music, I removed it. Next morning I found the uncovered part of my body checkered with ugly mosquito bites, the noiseless minute had deceived me and wrought the mischief during the few snatches of sleep that came to me that awful night. I am glad that I have seen India at its worst, so far as the climate is concerned, and that I have escaped with my life and my health unimpaired, but I will never advise any of my friends to go through a similar experience, as it involves great suffering and is attended by no inconsiderable immediate and remote risk to life.

THE PEOPLE.

India has, approximately, 300,000,000 inhabitants, four to one of the United States. The population is a very mixed one, composed of Hindus, Afghans, Mohammedans, Parsees, Thibetans, and other Asiatic races, Europeans and a mixture of Europeans and Asiatics, called here Eurasians, in Ceylon half-castes. The original East Indians were an Aryan race, which came from Central Asia by way of the Cabul river. The present Hindu race represents Aryan and non-Aryan elements. The typical Hindu is above average size, fine, erect, slender physique, long, very thin legs and arms, straight black hair, beard of the same color, light or heavy. The color of the skin varies from yellow to coal black. Many of the men are handsome; others, especially the common coolies, are often not only ugly but absolutely hideous, their faces approaching the appearance of a monkey rather than that of a man. The women are homely almost without exception; much smaller than the men and very spare even during old age.

The handsomest men and women are found among the Parsees, the fire worshipers, who came from Persia to India centuries ago. They are a thrifty people, fond of dress. The men wear a very strange head covering, which does not answer to the description of either a hat or cap. Imagine a black piece of stovepipe a foot in length, speckled with minute yellow dots, and turn in the top obliquely and you have as complete a description of the headdress of the Parsee as can be given. The women are dressed in flowing silk of vivid colors, and display a wealth of jewels attached to ears, neck, fingers and wrists. Bombay is the center of the Parsee population, about 100,000 in number. Their principal temple and ghastly graveyard are located here.

Social distinction is drawn in India in more definite lines than in any other country. It is a land of castes. There are more than 1,000 of these castes, which have very little in common with each other. The Brahmins or priests take the first rank, the warriors the second, and the merchants the third; then follow the different professions and trades. The caste of warriors is the only one which is permitted to hunt and to eat meat. There is never an intermarriage between a high caste man or woman with a lower caste woman or man, but in exceptional cases a promotion from a lower to a higher caste with all privileges belonging to such advancement may take place. The lower castes make themselves known by stripes and dots of all colors and designs on the forehead or face. A study of these distinctive marks would prove a very thankless task to the foreigner owing to the endless number of castes.

The religious life in India is as mixed as its population. In 1891 there were 207,731,727 Brahma followers, 7,131,361 Buddhists, 57,321,164 Mohammedans, and only 2,284,380 Christians, a rather discouraging showing for the millions and millions of dollars that have been spent in efforts to christianize the people. The slow progress of christianity in India is due, at least in part, to the character of the people. The complicated class distinction is one of the greatest obstacles. The high caste Hindu prides himself on the antiquity of his religion. He is firmly convinced that:

> "Antiquity, the nearer it was to its divine origin, perhaps perceived more clearly what things were true."—Cicero.

A high-caste Hindu, a very learned man, a magistrate in one of the eastern districts of India, expressed himself to me on this subject about as follows: "My religion is the oldest in the world. It was old before the religion of the Christians was known. I spent five years in England. I made careful observations and in consequence came to the conclusion that my people are better people than the people I observed in England. Crime is more common in England than in India. Why should I change my religion? The essence of our religion consists in leading a useful, pure life. We believe in progression in spiritual as well as in worldly affairs. As the muscle is strengthened by exercise, so constant efforts to reach a higher spiritual existence will improve progressively the spiritual part of men until perfection is reached. We do not believe in perpetual punishment after death, but in a gradual elevation until nirvana, a state of perfection, is reached. Missionaries can not change the religious views of high caste Hindus. Then, too, the manner of living and the way in which the missionaries approach the low caste Hindus are not calculated to excite their interest or to gain their confidence." This is what the Hindu said.

In conversation with me a Roman Catholic priest who came to India 26 years ago said: "We can do nothing with the adults in the way of converting them. The people appreciate our works of charity and our efforts to educate their children. We must plant the seed of true religion in the hearts of the children, where it will grow, but their parents are out of our reach. The high caste, educated Hindus have their fixed religious ideas from which they can not be diverted, and the low castes are in the firm grasp of the Brahmin and the Buddhist priests."

The natives are suspicious of the Europeans and are naturally proud and not easily approached. The poorest of the poor possess an inborn pride and manifest a spirit of reserve entirely unknown among the South Sea Islanders. There is no "Alloha" or "Talofa" greeting for the stranger in India. The faces are stern, the look shy, the bearing defiant and smiles few unless they are provoked by a liberal tip. The converted natives may conform on the surface with the teachings of the church to which they belong, but in their inner life they retain much of what they have been taught, and what they practiced before they changed their religious views; we can say of them as well as of their heathen brethren:

> "Some are good, some are middling, the greater part are bad."—Martialis.

And

> "Habit has produced the custom."—Ovidius.

Missionary work has done more good in supplying the starving with food, the sick with nursing and with medical treatment, the poor with clothing and in the education of children than in the christianization of the people. The door to the heart of the Hindu is charity.

The greatest virtue of the coolie is his willingness to work. It is the coolie who cultivates the fields, loads and unloads vessels and cars, cleans the streets, empties the cesspools and performs all other menial work, for wages which range from 8 to 32 cents a day. He has held his place in the competition for cheap labor against Chinese and Japanese, and against cheap workmen from other parts of the world. He meets the demand for labor in India and the low wages with which he is content has so far effectually prevented outside competition, and owing to the dense population and the severe struggle for existence which are in evidence everywhere, precludes the idea of a possible betterment of the condition of the laboring classes. The coolie has no desire to accumulate wealth; he is satisfied if by hard toil he is able to keep the wolf from the door. His needs are few, and what many a Chicago family spends every day for newspapers will support himself, his wife and children. From experience he can say:

> "Ye immortal gods, men know not how great a revenue economy is."—Cicero.

INDIAN ART.

India is a great art museum (Fig. 1, page 207). The ancient palaces, temples and tombs are the silent witnesses of the exquisite workmanship of native artists, who lived and worked here centuries before Solomon's temple was built. The masonry of many of these remnants of ancient architecture is the wonder of the leaders of the craft to-day (Fig. 2, page 208). The size of the stones, the cutting, placing them in positions, the fitting them together with such accuracy that cement of any kind was superfluous, in other instances the fitting together with metallic substances, are lost arts. The designs of the mosaics, the sculpturing and the wood carvings, the inlaid work are marvels of skill, patience and perseverance. The ancient artist and artisan made use of noble material on which to stamp indelibly the proofs of his skill. In short, nature supplies the material, art works on it.

> "Art can effect nothing without material, yet there is an inherent value in material, though untouched by the art of man. Perfection of art is superior to the best material."—Quintilianus.

Symmetry was above everything else the object of the ancient architect, mosaics, columns and arches were the details in carrying out his designs. The two pieces of architecture and design that impressed me most were the royal tomb,
Th ing air during th nares and the Cave Temple in Elephanta
would be difficult, y the former noted for its exquisite beauty,
panting for breath, at age and wonderful mural statues, cut
soda and from vigo to which allusion will again be made
throughout the night, regret that the influential and rich

of sleep. One night I had t s are now being built in imita-
night the to and fro motions road. Painters from Italy and France do the decorating. Plush and silk covered furniture is brought from Europe, and the old beautifully carved chairs, tables and other articles of furniture are stored away, sold for a song or given away to make room for things that are not adapted to the climate and that can make no pretention to art. It is very fortunate that Lord Curzon has taken the necessary steps to preserve Indian art by the erection of a great museum of art in Calcutta, in blessed memory of the late Empress Victoria, where the most valuable and interesting specimens will find a permanent resting place for the benefit of future generations of natives and visitors.

It is high time that in the three great cities of Calcutta, Bombay and Madras, associations of Indian art should be founded for the purpose of collecting and preserving specimens of ancient Indian art, and with the object of encouraging the native artists of to-day by patronizing them instead of importing furniture from foreign countries and imitating the artless style of the buildings of the Europeans. For the benefit of natives as well as of travelers, India should remain specifically Indian in dress, customs, agriculture, and especially in art.

(To be continued.)

Therapeutics.

[It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in every-day practice. Proper inquiries concerning general formulae and outlines of treatment are answered in these columns.]

Treatment of a "Cold."

In speaking of the treatment of a "common cold" Dr. Leonard Williams, in the *Clinical Journal*, London, uses this expression for a catarrhal condition affecting the nasopharynx, larynx or the larger bronchial tubes, in that cold or chill is supposed to be the principal factor in the causation. However, the author thinks that cold has nothing to do with the causation of the condition, but that it is due to irritation of the air passages from bacterial invasion.

The therapeutics of this condition consists in aborting it by washing the microbes out of the nasopharynx by douching and gargling. After filling the nasal douche with an antiseptic solution, the patient should be directed to introduce the solution into one nostril and at the same time keep the mouth open. In this way the solution will flow out of the other nostril instead of into the mouth. If the mouth is kept closed it will find its way into the larynx and esophagus. Therefore, the patient should always be directed to keep the mouth open when using the nasal douche. The author recommends that the solution should be warm and of a temperature not below 98 F. He prefers zinc sulphocarbolate in weak solution as *follows:*

℞. Zinci sulphocarbolatis	gr. vi	40
Aquæ dest. q. s. ad	℥iii	90

M. Sig.: To be used, warm, in the nasal douche.

A nasal catarrh, as suggested by the author, may be the beginning of whooping cough, and in this treatment the best measures are to be carried out to cut short the attack and to prevent grave sequelæ. So important is this form of treatment in the early stage of whooping cough that it is grave neglect when it is even delayed until the whoop has begun.

The following combination is recommended as a very efficient antiseptic used as a nasal douche:

℞. Acidi boracici	ʒii	8
Or		
Acidi carbolici	gr. x	65
Glycerini	℥ss	15
Infusi rosæ acidi q. s. ad	℥viii	240

M. Sig.: To be used as a nasal douche.

[Infusum rosæ acidum is composed of acid infusion of roses (red rose petals), ʒvi (25.) and dilute sulphuric acid ʒiii (12.): aqua destilata Oii (1,000).]

When the irritation is lower down in the air passages, in the larynx, the treatment can not be carried out so successfully. The most successful treatment here consists in the use of antiseptic oils such as eucalyptus, vaporized and inhaled frequently. In addition to this local treatment, mild purgatives should be given to keep the bowels well open, and a hot bath or hot wet pack given to increase the elimination from the skin. If headache is present, with a slight rise in temperature, a moderate dose of opium at bedtime is the best remedy. When administered early in influenza, the author regards opium as almost specific, and in ordinary colds its effect on the inflamed mucous membrane and irritated nervous system assists greatly in relieving the symptoms.

As a tonic after a cold no preparation is more beneficial than quinin, and it is recommended prescribed in the liquid form, as the powder is not so reliable in its action and has a greater tendency to disturb the stomach. When once there is failure in aborting the attack and active inflammation of the mucous membrane has set in, with a feeling of constriction, accompanied by a dry, hard cough, the proper treatment then consists in the administration of sedative or depressing expectorants and not stimulating expectorants. For this purpose the following combination is recommended:

℞.	Vini antimonii			
	Vini ipecacuanhæ, āā	m.x		65
	Spts. etheris nitrosi	m. xxx	2	
	Liq. ammon. acetatis	ʒii	8	
	Syr. limonis	ʒi	4	
	Mist. amygdalæ q. s. ad	℥i	30	

M. Sig.: To be taken at one dose and repeated in four hours, or half the quantity every two hours.

The foregoing combination should not be given when a valvular disease of the heart is present, as ipecacuanha and antimony are both very powerful heart depressants. After the congestion of the mucous membrane has subsided, stimulating expectorants are indicated, and for this purpose the following is recommended:

℞.	Ammon. carb	gr. v		30
	Tinct. camph. co. (B. P.)	m. xx	1	30
	Syr. scillæ	m. xxx	2	
	Syr. tolutani	ʒi	4	
	Infusi senegæ	℥i	30	

M. Sig.: To be taken at one dose and repeated every four hours.

Opium is one of the best remedies in aborting a cold, according to Yeo in *Clinical Ther.*, and it acts best when combined with other diaphoretics. Its effects on the capillary circulation of the respiratory passages is very beneficial in the initial stage of the attack.

In those patients who are inclined to disturbances of liver function opium preparations should be avoided and other diaphoretics substituted as follows:

℞.	Spts. etheris nitrosi	ʒiv	15	
	Liq. ammon. acetatis	℥ii	60	
	Salicini	gr. xl	2	65
	Vini ipecacuanhæ	m. xl	2	65
	Aquæ camphoræ q. s. ad	℥viii	240	

M. Fiat mistura. Sig.: One tablespoonful every four hours.

After the first twenty-four hours quinin is recommended, given in the form of the following effervescing mixture:

℞.	Potass. bicarb.		
	Sodii bicarb., āā	ʒi	4
	Ammonii carb.	ʒss	2
	Syr. aurantii	℥ss	15
	Aquæ q. s. ad	℥viii	240

M. Fiat mistura.

℞.	Quininæ sulph	gr. xii		75
	Pulv. acidi citrici	ʒii	8	
	Sacchari lactis	ʒi	4	

M. et divide in pulv. No. vi. Sig:: One powder dissolved in water and mixed with one-sixth part of the mixture and taken three times a day.

As to local remedies to cut short an attack of coryza the following is recommended in the form of an inhalation:

℞.	Liq. ammon. fortis	ʒi	4
	Spts. vini rectif	ʒii	8
	Acidi carbolici	ʒi	4
	Aquæ	ʒii	8

M. Sig.: A few drops of the mixture to be dropped on absorbent cotton and the vapor inhaled. Or:

℞.	Olei pini	ʒii	8	
	Camphoræ	gr. xl	2	65
	Liq. ammon. fortis	ʒi	4	
	Spts. rectif.	℥i	30	

M. Sig.: To be used in the form of an inhalation.

As an anodyne spray, Shurley recommends the following:

℞.	Mentholi	gr. i		06
	Alcoholis	m. v		30
	Calc. phos. precip	gr. v		30
	Aquæ q. s. ad	℥ii	60	

M. Sig.: To be used as a spray.

As a sedative and astringent the following is of service:

℞.	Cocainæ	gr. v		30
	Alumini	gr. x		65
	Aquæ mentholi	℥i	30	

M. Sig.: To be used locally as a spray.

Kyle recommends in some cases the following oil spray:

℞.	Camphoræ	gr. i		06
	Mentholi	gr. iii		20
	Acidi carbolici	m. ii		12
	Liq. albolene	℥i	30	

M. Sig.: As a spray.

As an inhalant the ordinary tincture benzoini comp. is very efficient; one teaspoonful is floated on a pint of hot water and the vapors inhaled.

Creosote may be used in the same manner, using from ten to fifteen drops (.65-1.00) to a pint of hot water.

Bartholow recommends the following combination:

℞.	Acidi carbolici	ʒi	4
	Tincturæ iodi	℥ss	15

M. Sig.: From ten to fifteen drops in a pint of hot water as an inhalation.

As an abortive remedy the following is of service, but must be prescribed with care:

℞.	Cocainæ hydrochlor.	gr. viii		50
	Mentholi	gr. iv		25
	Salol	gr. lxxv	5	
	Acidi boracici	ʒiv	15	

M. Sig.: A small amount to be insufflated into the nares three or four times daily.

As a spray the following is recommended:

℞.	Mentholi	gr. viii		50
	Camphoræ	gr. v		30
	Liq. petrolati	℥i	30	

M. Sig.: To be used in the atomizer as a spray after thoroughly washing the affected areas. As a vapor to be inhaled the following is recommended:

℞.	Mentholi	ʒiss	6
	Eucalyptol	ʒi	4
	Liq. albolene	℥i	30

M. Sig.: A few drops to be floated on a small amount of water, placed over a spirit lamp and inhaled.

Medicolegal.

Privilege Extends to All Proceedings of Judicial Nature.—The Supreme Court of Michigan says, in the case of Dick vs. Supreme Body of International Congress, that the by-laws of the defendant order provide that its decisions shall be final and binding on every member and his beneficiaries, and that no suit shall be commenced by either against it. In this case use was made, over objection, of an affidavit of a physician, consulted by the insured, to the effect that the latter had been sick prior to a certain date. Did the defendant violate a law which was prescribed for its guidance when it admitted in evidence the affidavit in question? The legislature has said: "No person duly authorized to practice physic or surgery shall be allowed to disclose any information which he may acquire in attending any patient."

Section 10,181, Compiled Laws of Michigan of 1897. The proceedings were in their nature judicial, and there can be no doubt that the legislature had power to prescribe rules which it was the defendant's duty to observe. The statute is one passed for the sole purpose of enabling persons to secure medical aid without betrayal of confidence. Did the legislature, in passing the statute, which prescribes a rule of evidence to be observed in judicial proceedings, intend to permit this confidence to be betrayed in any judicial proceedings which it had the power to regulate? To impute any such intention to the legislature was to assume that it designed to defeat its manifest purpose. There is nothing in the statute to limit its operation to any particular judicial tribunal or to any particular class of judicial proceedings. We must therefore assume that it was intended to extend to all proceedings of a judicial character which the legislature had the power to regulate. This statute was, therefore, violated when the physician's affidavit was used as testimony. When the defendant rejected the plaintiff's claim because of testimony admitted against objection, and which the law in positive terms forbade it to consider, there was a denial of the hearing to which the plaintiff was lawfully entitled. It was the defendant's duty to observe the law. prohibiting the use of this testimony. It was the plaintiff's right to have that law observed. This right and this duty were just as clear and obvious as if they had been expressly stated in the by-law which provided for the hearing of the plaintiff's claim. If such by-law had in express terms provided that this law excluding the physician's affidavit should be observed, no one would for a moment maintain that a determination by the defendant in violation of such provision was binding on the plaintiff. The only distinction between the supposed case and the actual one was this: In the supposed case the provision for the observance of the law was expressed; in the actual case that provision was necessarily implied. This distinction afforded no ground for the application of a different legal principle. The court thinks it may also be said that the statute in question not only forbade the use of the physician's affidavit as testimony, but by necessary implication forbade all judicial tribunals (including the judicial tribunal of the defendant) from determining controversies (at least without the consent of the parties) on such testimony, and that the law would not permit the defendant to retain the unlawful advantage obtained by violating its prohibitions.

Liability for Attendance on Employe and Assistance.—The Supreme Court of Montana says that in the case of Bond vs. Hurd an action brought by a physician, the physician was called to attend a man who had been sent by the party sued to receive some of the latter's horses gathered in a certain county, and was injured in moving the horses by being thrown from one of them, and the plaintiff, finding him seriously injured, called in another physician to assist him. The cause of action included, besides the plaintiff's own account for medical services, an account for medical services rendered by the assistant physician, which had been assigned to him. The only evidence in the record on which agency could possibly rest was that of two telegrams passing between another party and the defendant—a telegram of such other party to the defendant announcing that the man had been hurt, and asking if he would pay the "doctor's bill," and the defendant's telegram in reply, announcing that he would do so. The plaintiff saw this telegraphic answer of the defendant, accepted the offer therein contained, and acted on it. No direct authority was given this other party to employ a physician, so that any agency on his part was implied from the telegrams. However, the court says, no agency could be implied from these telegrams which would authorize this party to delegate to the plaintiff the right to engage the assistance of other physicians, and bind the defendant to liquidate their charges. The agent's power to delegate authority is statutory, in Montana; and the testimony did not disclose that this party referred to lawfully delegated to the plaintiff authority to employ an assistant, within any of the provisions of the statute. The court below took the ground that an emergency arose which justified the employment of the other physician. But, in the opinion of the Supreme Court, neither substituted agency nor emergency was sufficient to hold the defendant liable for the charges of the assistant physician. Presumptively, it says, the plaintiff, when he was employed, assumed that he was a competent physician and capable of taking care of the case for which he was employed without assistance. If he concluded that assistance was required, before procuring the same it was his duty, if he desired to hold the defendant liable for the payment of the bills of an assistant, to communicate with him and obtain his consent to the employment. If he had the right to employ the other physician and make the defendant liable for his services, he would have a like right to employ as many other physicians as he might have deemed necessary and compelled the defendant to have paid them all. Continuing, the court says that there would be very grave doubt as to the liability of the defendant to furnish to the injured man medical assistance on the facts disclosed in the record, aside from the above telegrams. The accident by which the man was injured may have arisen from his own personal negligence, or from a direct violation of the instructions given him by the defendant. The law is by no means settled that an employer is liable to furnish an employe with medical aid under all circumstances. Many courts of last resort have held that even a railroad company is not liable to furnish an employe with medical assistance in case of accident. There the work of the employe is at all time dangerous in its character, and the reason for holding the railroad company liable to furnish such medical assistance in case of accident is much stronger than it is when an individual employs another to perform a service which is not dangerous in itself. After an investigation of authorities, the court is of the opinion that the holding of the Supreme Court of Indiana in matters of this character is the correct one, and should be followed. That court, in the case of the Terre Haute & Indianapolis Railroad Co. vs. McMurray, 98 Ind. 358, seems to place the liability of a railroad company on the ground of emergency and urgent necessity. The case of Terre Haute & Indianapolis Railroad Co. vs. Brown, 107 Ind. 336, is also referred to, and as a much stronger case than the one at bar. And the Supreme Court of Montana says that it is satisfied that the record in this case failed to show any such emergency as authorized the employment of an assistant physician, or that the assistant physician was employed by any one having competent authority to that end.

3. Treatment of Carcinoma Cervicis Uteri in Advanced Stages.—Given a case of cancer of the cervix uteri, Bovée says that it is necessary to consider the age of the patient, the family history, the apparent duration of the disease, the variety of the disease, the amount of excavation already resulting from the disease, the amount of infiltration of adjacent tissue, the involvement of other, distant parts, and the presence of other physical disabilities that preclude radical surgical operations. Bovée finds that the disease makes more rapid progress in young women than in those far advanced in years, and usually causes death in eighteen months, if left alone. The woman of from 60 to 90 usually will live much longer than the woman of 28. A family history of cancer has a deterring influence regarding radical surgery. Severe surgical operations, involving appreciable mortality rates or a marked degree of additional suffering, should not be employed in the treatment of carcinoma of the uterine cervix, except in very early cases. According to the reports of exhaustive microscopic examinations of the tissues surrounding the uterus in cancer of the cervix, we have no means of knowing before operation that eradication is certain in any given case of the disease; hence, such attempts must be reserved for the very earliest and most promising ones. Bovée believes that the galvanocautery and the curette combined furnish the very best local treatment, so far as influencing the progress of the disease is concerned. The curette should be used carefully but thoroughly, the flow of blood being controlled by either gauze or clamp compression. The galvanocautery is then carefully employed to destroy practically all tissue between the cul-de-sac of Douglas and the bladder and, laterally, between the ureters. Great care should be exercised that bladder, ureters, peritoneum, and rectum be not penetrated nor injured by overheating. Vaginal douches of from .5 to 2 per cent. solution of potassium permanganate he has found the most satisfactory to control a malodorous discharge following the use of the cautery. When the cervix is much infiltrated, the canal obstructed, and the discharges, becoming foul, are confined in the uterus, evacuation and provision for future drainage is the proper treatment.

4. Study of Lactic Acid Formation.—Palier bases the following laws on what takes place in the test tube and, as he believes, also in the stomach: 1. Lactic acid develops in all organic substances containing carbohydrates, whether sugar or starch; and in some substances even while yet in solid form, such as bread and meat; for instance, at certain seasons which are especially favorable to bacterial development, some lactic acid exists already. 2. Lactic acid formation is due in all cases to bacterial development, even the so-called sarcolactic acid of meat. 3. Lactic acid does not give the usual reaction with the usual test when an inorganic acid is also present in sufficient strength. 4. Its development is hindered when there is an antiseptic present such as HCl, for example, but the lactic acid formed before the HCl was added is not destroyed when the latter is added. 5. HCl enters in combination with albuminoids and after some time it does not give the usual reaction, though it was warmed when it was first added; and then bacteria appear and lactic acid begins to form, the latter in substances containing carbohydrates. The bacteria in the stomach bringing about lactic acid formation may be various; but whenever there is alimentary stasis with deficiency of HCl, there is usually found a bacillus, which Palier calls the *Vibrio geniculatus ventriculi*. Experiments have shown him that the presence or absence of lactic acid in the stomach contents can give us some information concerning the condition of that organ, but it is positively not pathognomonic of any particular affection, and any one who will rely much on this for making a diagnosis of cancer, for instance, is surely apt to err, though he may succeed in guessing right a few times. If the acid exists in the stomach contents in small quantity, it is absolutely of no significance; if it is in large quantity it can be easily detected by tests described. So long as the acidity is not very high there is not any alimentary stasis worth mentioning.

7. Digestive Disturbances in Infants.—Holt believes that disturbances of digestion resulting from an excess of fat are quite as serious, if not quite so obvious, as those which follow the use of too high proteids. Even those who give special attention to infant feeding have been slow to learn the infant's capacity with respect to the digestion of fat. Others, who have given the question less attention, have fallen into error in one of two ways: In following the formulas of the books instead of using an ordinary milk, with a fat content of 4 per cent., they have substituted rich Jersey milk, containing from 5 to 5.5 per cent. fat, thus giving more fat than was supposed to be given. Or, the mistake is made of intentionally increasing the fat, almost without limit, for the purpose of overcoming chronic constipation. Illustrative cases are cited by Holt, as follows: I. Overfeeding with high fats, rapid increase in weight and progress in development until eight months; then general convulsions, followed later by tetany, laryngismus stridulus, fatty liver (?). Recovery after three months' illness. The points of interest in this case were (1) the long period during which the child bore the high percentage of fat without any apparent disturbance; (2) the severity of the nervous symptoms, the suddenness with which they came on, and their long duration; (3) the prolonged disturbance of the digestion and general nutrition; (4) the large liver, and stools consisting of almost pure fat. II. Prolonged feeding with high fat, notwithstanding which constipation and the development of moderate rickets, followed by acute disturbances of digestion with repeated convulsions. III. Overfeeding with fat; convulsions. Recovery. IV. Habitual vomiting aggravated by high fat; serious gastric catarrh, finally cured by stomach washing. V. Feeding with high fat; eczema, habitual constipation, and finally habitual vomiting. Recovery after the fat was reduced to 3 per cent. Holt advises the examination of all milk to be used for feeding purposes and that the physician, in order to interpret correctly the result of these examinations, learn to think in percentages. Children differ very much in their capacity to digest fats, but there is a limit with each child which can not be exceeded without causing trouble. Holt believes that 4 per cent. of fat is about the limit for the average child. Whenever there are marked symptoms of either gastric or intestinal indigestion, the fat should be reduced much below the normal 3 or 4 per cent.

19 Pneumococcus Arthritis—Report of a Case. W. H. Witt, Nashville, Tenn. With Pathologic Report. William Litterer, Nashville.

16. Conservative Gynecology.—Harrison's article is a review of, and comment on, conservative gynecologic operations.

17. Management of Pneumonia.—The first consideration in the treatment of pneumonia, says Osborne, should be the establishment of hygienic surroundings, such as a well ventilated room, with plenty of fresh air. That pneumonia can abort itself and that it can also be assisted to abort, may not be frequently, but often is, true. He says: "The profuse sweating caused by a gram of antipyrin, with the action of some brisk purge, followed by morphin to stop the pain, and dry cupping, or, if preferred, a hot poultice, may and often does abort a case of pneumonia." The old treatment with aconite and veratrum viride will probably give the same results, although Osborne prefers not to use these

drugs because of the fear of prolonged cardiac depression. In cases *not aborting, the* nutrition should be sufficient, but not so forced as to cause gastric flatulence or tympanitis. The nutrition should consist of milk, a quart in twenty-four hours, two raw eggs a day, given in bouillon, with coffee or with sherry or brandy, as seems best. Expressed beef juice, which means more than the blood from meat, is one of the best heart muscle stimulants and should be given in ounce doses three or four times a day. For the bowels, use small glycerin enemas, or, if necessary, a small amount of some saline, such as Hunyadi water. Sponging the extremities and the abdomen (not the chest) with tepid water will reduce the temperature. Gentle massage of the extremities promotes excretion of muscle toxins. Insufficient leucocytosis demands some nuclein preparation, such as nucleic acid, in the dose of one grain, three or four times a day, or thymus, in doses of three grains. Osborne favors warm, moist applications, preferably the old flaxseed poultice, bound tightly to the chest during the first stage to mitigate pain and to add to the general comfort of the patient. Such applications should not be allowed to become cold. He doubts the value of such applications in children, believing that they play a part in causing an empyema. In stopping the use of the poultices, it is important to reduce their size gradually and then to put on some warm, dry absorbent cotton. *For the irritating cough*, he prefers codein in small doses so as not to depress the respiratory center. The best stimulant for the bronchial mucous membrane he believes to be ammonium chlorid in small doses, especially if combined with a very small amount of ipecac and put up in an acid preparation, such as syrup of citric acid or dilute phosphoric acid in watery solution. Alcohol should not be relied *on for a long time in cardiac depression*, although for a short time it will tide over such depression and whip up a flagging heart. The dose of whisky should be such as not to give strong odor to the breath, nor to cause a dry skin or a bounding pulse, but just enough to keep the surface of the body warm and the pulse regular. If the heart still fails, and the pulse is bad, not more whisky should be given, but other cardiac stimulants. *Many cases of delirium* are caused by an overdose of alcohol. Nitroglycerin, 1/200 of a grain, every three to six hours, or a hypodermic of 1/100 of a grain, will give a flagging heart a start and allow time to get the action of other drugs. Venesection of a few ounces of blood will relieve cyanosis, jugular throbbing and a laboring right heart. In any stage of the disease, an irregular pulse tension demands strychnin, 1/30 of a grain, every six hours. Caffein, in the form of coffee, should be given from the beginning of pneumonia, at least once a day, in the morning. Coffee is a food and a cardiac stimulant and tonic. Aromatic spirits of ammonia, or camphor water or spirits are good substitutes for caffein. In acute heart failure a hypodermic injection of a saturated solution of camphor in olive oil may be used. Adrenalin or suprarenalin solution 1 to 1,000, may be used in drops on the tongue, 5 drops every fifteen minutes, several times in an emergency, or 5 drops every three hours regularly. Osborne sounds a note of warning against using suprarenal extract in large doses, or for too long a time, as it may cause depression. Oxygen Osborne considers of undoubted value in emergencies, but says that it should not be considered curative. High injections of normal saline solution are indicated when the kidneys are not acting well or the patient not taking sufficient liquid, provided there is no edema anywhere. During convalescence from pneumonia, if the pulse and heart are weak, he favors the use of tincture of strophanthus in from 5 to 8 drop doses every six hours. To combat sleeplessness, chloral and hyoscin should be used. Ergot is indicated to strengthen a weakened circulation. Severe headache may be often well combated by an ice cap or a saline purge. Profuse perspiration should not be discouraged at any time. Osborne gives no opinion as to the value of the serum treatment of pneumonia.

23 *Cardiac Collapse During Examination of a Post-Pharyngeal Abscess; Incision; Circulation Re-established and Maintained for Four Hours by Massage of the Heart; Death D. Cheever, Boston.

22. **Finney's Gastroduodenostomy.**—Gould calls attention to the following details, which differ from those in present use in the performance of this operation: 1. The placing of the clamps. 2. Opening of stomach and duodenum; trimming mucous membrane. 3. Omission of guide stitches. A fold of the anterior wall of the stomach, three to four inches *long, is picked* up parallel to and about one-half inch from the greater curvature. The ends of the clamp are not freed, but are pushed up tightly until the *inner jaw* rests against the pyloric sphincter, about one-quarter to one-half inch below the free edge of the fold, where they are made fast. The duodenal clamp encloses a similar fold, as it goes obliquely across the bowel from the free edge to the pylorus, and is pushed up until its inner jaw touches that of the stomach clamp, where it is fastened. The handles of the clamps are brought together, the pyloric angle is thus put on a stretch and incision can be made into any part of the area held by clamps or into the pyloric angle without hemorrhage. The duodenum and stomach folds lie side by side, thus obviating the necessity of guides. The two folds are *fastened together* with a continuous seromuscular stitch beginning at the pyloric angle. The stomach incision is made first and is carried down until the mucous membrane pouches freely between the cut muscular walls. The duodenum is then opened until the mucous membrane of the stomach is met at the pyloric angle. It is occasionally necessary to trim off the mucous membrane from the edges of the duodenal incision. The *pouching of the mucous membrane* is removed from the stomach by cutting with scissors close to one muscular edge, returning on the other side. The completed incision leaves a tongue-like process made up half of gastric and half of *intestinal* walls. The two edges of the tongue are sewed together with a continuous through-and-through stitch, which starts from the apex of the tongue and goes across to its base. At this point it is interrupted with a tie before continuing the suture across over the *front*. When within an inch from the pylorus and the suture over the front is nearly completed, the clamps are loosened to relieve the tension and to allow the last few stitches to be placed. Remove the clamps and bury the suture with a seromuscular stitch. The closing in of the inaccessible pyloric angle is made easy by the introduction of the writer's mattress stitch. The rest of the seromuscular stitch may be continuous.

23. **Cardiac Collapse and Circulation Re-established by Massage of Heart.**—In Cheever's case death was evidently caused by cardiac collapse due to shock, in a patient whose condition of extreme exhaustion made the necessary *manipulations* in preparing to open the abscess a source of grave danger. *Death was not due to suffocation;* there was no inhalation of pus, as the abscess was not evacuated until after effort at resuscitation had been begun. There was *no serious* mechanical obstruction to respiration, hence no *indication for* tracheotomy; but a rubber tube was introduced into the larynx to supplement the usual method of artificial respiration by direct insufflation, which proved very satisfactory. Later, a tracheotomy was done when the onset of rigor mortis made the reinsertion of the tube through the mouth difficult. Cardiac massage by rhythmical pressure at the rate of 60 to the minute over the third, fourth and fifth left costal cartilages was continued with the *artificial respiration* for four and one-half hours. It seemed that the circulation of the blood was restored and maintained and that the blood was fairly well *oxygenated*. The body warmth

was artificially kept up, stimulants supplied and efforts made to raise the blood pressure, but without avail.

31 A Case of Sciatic Neuritis with Paralysis, Following Malaria. William G. Russell, New York.

24. **Healing of Tuberculosis.**—Why, asks King, if all are subjected to the infection, does the vast majority escape and only a comparatively small proportion develop a recognizable tuberculous lesion? The painstaking and exhaustive inquiry into the past history of a tuberculous invalid is often full of surprises. One feature, for instance, recurs with such persistent frequency that it merits some attention, and that is the striking difference in time between the presumptive evidence of disease and the first demonstrable evidence, so that at the onset of the recrudescence the original outbreak has been forgotten or regarded as having no relation to the present trouble. So that it is extremely probable that the initial lesion following a tuberculous infection is often obscure in its clinical manifestations and frequently escapes identification. There is nearly always a prompt and very often successful tendency on the part of the organism to a more or less complete repair followed by an interval of apparent health. Following this interval, which may extend into a period of years, there is a strong tendency to relapse. More often than is supposed the real incipiency of the disease is marked by sharp constitutional disturbance. King calls attention to the frequency with which it is possible to trace in the history of a tuberculous patient a first presumptive evidence of disease, followed by a more or less extended interval of apparent health before arriving at the demonstrable onset, which, in the light of the history, must be considered a recrudescence. Whatever may be the facts in an individual case, the safest and most practical policy lies in regarding every apparent recovery from tuberculosis as merely an arrest of the disease, brought about by an acquired immunity which suitable conditions are very prone to destroy. King says that if we are ever to be able to recognize the presence of tubercle during the period of arrest following the first and unrecognized onset, we are most likely to do so through the discovery of definite reactions in the blood serum of the infected. The generally accepted prognostic significance of a Diazo reaction in tuberculosis has application chiefly, if not solely, to the last stages of the disease, and when temporarily present in the early acute manifestations, or in acute exacerbations of chronic lesions, need not necessarily indicate an unfavorable termination. Its disappearance, if present, would be one of the first clinical evidences of improvement.

25. **As to Eating.**—Under the name euphagia, Einhorn describes the correct manner of partaking of food. Violations of these laws are a frequent source of diseases of the digestive system. He mentions some of the factors, such as good company, pleasant conversation, attractive service, etc., which, in addition to a palatable mode of preparation, contribute to make eating the pleasure it normally should be. Tachyphagia, or hasty eating, is a common evil. It gives rise to gastric and intestinal catarrh, hyperchlorhydria and other digestive disturbances. Bradyphagia, eating too slowly, is a comparatively rare occurrence, and is observed mainly in neurasthenics. Two cases are cited illustrating this condition, one patient taking half an hour to consume a glass of milk. The difficulty in eating was explained by the psychic excitement subsequent to the sitophobia and bradyphagia. The patient was put on a more liberal diet and advised to eat more quickly. The second case required twenty minutes for the ingestion of half a plate of soup and twenty-five minutes for a cup of milk. On a more substantial diet and more rapid eating the patient improved. The treatment consists in suitable advice as to when, how and where to eat. The removal of bradyphagia will frequently smooth the path to convalescence and enable the patient to get entirely well.

28. **Spleenless Men.**—Carstens cites two cases, one of sarcoma of the spleen and one of splenic anemia, to prove the great value of splenectomy in some cases. Both patients are now in every way well. The histories also show the value of blood examinations in obscure cases, inasmuch as they enable us not only to make the diagnosis, as a rule, but also point the way to an operation or to non-interference, as the case may be. It has been demonstrated that spleenless men can live in perfect health and that there is no difference between the blood of such men and the blood of those who have not been subjected to splenectomy.

38 *Decapsulation of the Ovaries in Ovarian Dysmenorrhea. George G. Eitel, Minneapolis
39 *Feeding of Typhoid Patients.* John Sutherland, Pierpont, S. D.

37. **Stricture of Lachrymonasal Duct.**—Hughes believes that this condition is more common than is supposed usually and that in the majority of instances it is due to disease of the nasal mucosa, to bony hypertrophy of the turbinated bodies, or to deviations of the nasal septum, and occasionally to error of refraction. A rather intimate knowledge of the conditions, with their proper treatment, is an essential factor to success in the care of disease of the tear channel. Many cases may be effectually treated by removing the primary cause. If relief is not obtained, then the punctum may be slit by the iris scissors. This failing, the entire duct should be slit up and graduated stretching resorted to. The galvanic or chemical cautery may be used with good results. The use of astringents is highly useful in the treatment of chronic inflammation of the tear sac. Proper attention should be given to the correction of any deviations from the normal as regards the general health. Locally, gradual dilation with Bowman's probes, from No. 1 to No. 6, is usually sufficient in the majority of cases.

38. **Decapsulation of Ovaries in Ovarian Dysmenorrhea.**—Eitel proposes this procedure for cases of dysmenorrhea of ovarian origin where the ovaries are covered with a tough and greatly thickened serous covering under which are found small cysts varying in size from that of a small pea to a small marble. The technic of the operation is as follows: The ovary is brought into clear view through a median abdominal incision, and one hemostatic forceps is placed at the

juncture of the utero-ovarian ligament and the ovary and another on the upper border of the broad ligament close to the ovary (lateral). By means of these two forceps the ovary is held by an assistant in the proper position while the operator makes an incision with a sharp scalpel from the ovarian ligament across the ovary to the attachment of the broad ligament, through the covering, and then carefully dissects one side and then the other down as far as cysts are encountered. The flaps of the covering of the ovary are now trimmed off, preferably by means of a pair of scissors. The utero-ovarian ligament then is shortened by doubling it on itself in a similar manner as is in vogue in shortening the round ligaments, in order to hold the uterus in a normal position. Hemorrhage can easily be controlled by pressure clamps and fine ligatures. Eitel says that there is absolutely no danger of adhesions forming, except perhaps in cases where there exists or has at some time existed an inflammatory condition which produced adhesions that had to be broken up at the time of the operation. In two cases where he had occasion to reopen the abdomen some months after the first operation, Eitel failed to find any adhesions. The result in every case in which this method has been tried has been an excellent one, and cases in point are cited.

44 *Buried Sutures. Edmund A. Babler, St. Louis.
45 Eyestrain as a Cause of Migraine. W. A. Shoemaker, St. Louis.

44. **Buried Sutures.**—Babler reviews the origin of the buried suture, considering silver wire, silk, linen and catgut, and expresses his preference for the latter, especially when prepared by the cumol method as laid down by N. B. Carson. He says he knows of no instance where chromicized gut prepared by this method has caused any subsequent trouble. He emphasizes the following points: 1. Do not dehydrate the catgut insufficiently or at too high a temperature or the gut will be brittle. Dehydrate slowly. 2. Do not tie the gut tightly. 3. Do not place the dehydrated gut in cold cumol; have the cumol at 100 C. but extinguish the flame under the cumol boiler before placing the gut in the cumol. 4. Use a large cumol boiler so that a large quantity of gut can be sterilized at one time. 5. Brittle catgut is due to insufficient dehydration or to placing the dehydrated gut in cumol below 100 C. 6. Every step in the technic must be carefully performed, and perfect asepsis must be duly observed. 7. Place the glass tubes and the cotton plugs in the sterilizer for one hour each day for three consecutive days before placing the sterile gut in them. 8. Non-absorbable chromicized gut is far more irritating than silver wire. 10. Chromicized gut prepared after the modified cumol method is readily absorbed and perfectly reliable.

47 Pleurisy with Effusion and Empyema. Joseph K. Swindt, Pomona, Cal.
48 *Some Remarks on Hysterectomy, with Summary Report of 100 Cases. W. W. Beckett, Los Angeles.

48. **Hysterectomy.**—Beckett makes the following summary of 100 cases of hysterectomy. Of this number 46 were for fibroid growths, 18 for malignant disease, 27 for chronic endometritis, with diseased tubes; 8 for procidentia, 1 for imperforate os. The youngest patient was 16 years old, oldest, 71. Vaginal hysterectomy was performed 72 times; suprapubic, 28 times. Four patients died. One from pulmonary embolism the third day after operation; one from malignant stricture of the bowel seven days after operation; one from surgical shock, and one from exhaustion. Of the malignant cases, 6 have recurred; the earliest one month after operation, the latest one year after operation. In 3 cases there was alarming postoperative hemorrhage, one occurring six days after operation, one eight, and one nine days. In one case clamps only were used; in one case ligatures only, and in the other both clamps and ligatures were used. In each case clamps were reapplied for twenty-four hours. All recovered without further interruption. Whenever possible one ovary was left, and in some cases both. In the case of the 16-year-old girl with imperforate os, the uterus was dilated to the size of a seven months' pregnancy and its cavity filled with retained menstrual fluid. The right ovary was cystic and of about the size of a small orange. In the left side there was an ovarian cyst the size of a fetal head. The left fallopian tube was twelve inches long and distended with menstrual fluid. In 3 cases dermoid tumors complicated the operation. When hysterectomy was done for procidentia, anterior and posterior colporrhaphy was also performed. One patient, after a supravaginal hysterectomy, had a slight, irregular menstruation for nearly two years following the operation. In this case only one ovary was removed.

49 Narcosomania, with Report of 21 Cases. Thomas H. Evans, Philadelphia.
50 Illustrative Cases Due to Eyestrain with Explanatory Remarks Concerning Them. Ambrose L. Ranney, New York.
51 *Review of Exophthalmic Goiter and Its Treatment. Wm. O. Hewitt, Attleboro, Mass.
52 *Abuse of the Cystoscope in Prostatic Disease. G. Frank Lydston, Chicago.
53 Some Practical Methods of Hydrotherapy for General Practice. Eliot Gorton, Summit, N. J.

51. **Quinin in Exophthalmic Goiter.**—Hewitt speaks well of the use of quinin in the form of sulphate and the neutral bromid in the treatment of this condition. According to Paulesco, quinin produces a vasoconstriction of the vessels of the head and neck, thereby rendering the goiter smaller, diminishing the pulse rate, and even reducing the exophthalmus. Of three cases under Hewitt's observation, all began with a 5-grain gelatin coated pill of the neutral bromid of quinin, morning and evening; two of the patients are taking twenty grains a day; the third fifteen grains. None have complained of symptoms of cinchonism. One patient under treatment for thirteen months has increased in weight, the nervous symptoms have largely disappeared, a troublesome diarrhea has improved, and the goiter and exophthalmus are much less noticeable. The other two cases show a decided gain in strength and general improvement.

52. **Cystoscope in Prostatic Disease.**—Lydston says that when the diagnosis of prostatic obstruction is clear the indication for radical operation is also clear, the application of this statement being modified only by the conditions governing the individual case. Any exploration of the bladder which is unnecessary to the establishment of a practical working diagnosis is not only useless but exceedingly dangerous. Cystoscopy is especially dangerous and, where not absolutely necessary, is especially to be avoided because of the traumatism and subsequent danger of infection which the insertion of the instrument necessitates, and the frequent necessity of anesthesia with prolonged exploration of the bladder. The use of the cystoscope, especially when anesthesia is employed, rapidly compounds the immediate danger to the patient, and the subsequent danger of operative procedures. A properly performed radical operation is much less dangerous than a cystoscopic exploration. The use of the cystoscope rarely accomplishes more than the gratification of the curiosity of the operator in the establishment of refinements of diagnosis. So far as the diagnosis of stone is concerned, the use of the cystoscope is superfluous. Whether the presence of stone be established or not, a radical operation for the removal of the

prostate is necessary. The stone can be removed at the same time. There are exceptional cases of posterior median obstruction and of prostatic overgrowths at the neck of the bladder in which the cystoscope is necessary. These cases are safer for exploration than the orthodox type of prostatic obstructions, but even in them diagnosis can usually be established without the cystoscope, and where this can be done the use of that instrument should be avoided.

54 *Complete Removal of the Shaft of the Tibia for Osteomyelitis, with Restoration of the Bone. George Ben Johnston, Richmond, Va.
55 Toxemia and Infections as Causes of Insanity. Frank Stephenson, Syracuse.
56 The Alexander Operation—Its Immediate and Remote Results. James E. King, Buffalo.

54. **Removal of Shaft of Tibia.**—All Johnston's cases occurred in young males and the trouble was always traceable to a trivial injury. The tibia was involved in five instances and the fibula in one. There was a remarkable variation in the degree of virulence of infection and the extent of destruction of tissue was dependent on the character of the infection. When the latter was severe there were profound constitutional symptoms. Sometimes the condition was mistaken for "growing pains," rheumatism, or erysipelas. Regeneration in all these cases was entirely of periosteal origin, was rapid and complete and deformity resulted only in such cases as had suffered destruction of the epiphyseal line. Deformity never results where a disc of bone is left between the shaft and the epiphysis. The companion bone invariably took on compensatory hypertrophy. In acute cases the time to operate is as soon as possible. In subacute or chronic cases, where the surgeon may elect the time of operation, it is well to defer it until new bone tissue has begun to appear. The operation should consist of free incision and a complete removal of all diseased bone, sparing the periosteum as much as possible. The curette should be avoided, or used very cautiously. The strictest antiseptic precautions must be observed. The after-treatment advocated by Johnston consists of the maintenance of aseptic conditions, avoiding too frequent and rough dressings, immobilization of the leg in a fracture box, carefully shaping the parts as bone tissue develops, by bandages or adhesive straps; protecting the young bone by means of plaster of paris; abstaining from use of the limb until the new bone is capable of sustaining the weight of the body, and looking after the general health.

65 Some Newer Conceptions of the Nature and the Management of Bright s Disease. Alfred C. Croftan, Chicago.
66 Why Digital Exploration Through the Internal Inguinal Rings Should Be Made in Conjunction with Every Alexander Operation. A. Goldspohn, Chicago.

61. **Pyoktanin as a Surgical Agent.**—Friend has found pyoktanin useful in ulcers, burns, inflamed wounds and malignant neoplasms. It may be powdered directly on the surface of large purulent wounds and ulcers until a firm scab is formed, which must then be abandoned to spontaneous desquamation; or it may be employed as a dusting powder mixed with talcum, starch or sugar of milk in the strength of 2 per cent.; a 2 to 10 per cent. ointment, using lanolin, lard, cosmolin or vaselin as a base; pyoktanin pencils to be dipped in water and passed over the ulcerated surfaces, and solutions varying in strength from 1 to 1,000 to a saturated aqueous solution. Friend has made use mostly of the latter preparation. Burns of the second and third degree, quite extensive in size, as well as large varicose and specific ulcerations and osteomyelitic bone fistulæ, were treated with a saturated solution of the drug with excellent results. A solution of 1 to 1,000 was used in irrigating wounds, such as those following lymphadenitis, with good results. The chief advantages of the use of pyoktanin are: 1, The rapidity of action; 2, its drying tendencies of the weeping wound surface and consequent cutting short of the suppurating process; 3, the prevention of adherence of the gauze covering the ulcerated area, and in consequence, the minimum of disturbance to the newly-formed epithelial elements; 4, curbing of excessive granulation tissue; 5, non-irritating, non-poisonous and anodyne effects; 6, ease of application; 7, cheapness.

62. **Infant Mortality.**—Butler finds from a study of vital statistics that there has been a decided yearly increase in infant and early childhood mortality from all causes during the past decade in Chicago. It appears that there has been a decided reduction in the death rate from gastrointestinal and kindred diseases; this was most marked in 1900, since when the drinking water has been greatly improved. Prior to 1900 there seems to have been a variation in the yearly death rate, but since then an unvarying decrease. No one factor seems to explain fully all the figures given. The condition of the water, however, seems to bear an especially important relation. Milk inspection, too, has assisted greatly in so far as it has resulted in a pure, wholesome milk, undiluted and carefully and promptly handled. The education of the people by the profession and the greater interest taken in pediatrics have been of incalculable value. Lastly, the conditions of the poor, among whom infant mortality is by all odds the highest, has improved considerably.

67 Plea for the Voluntary Admission of Certain Types of Insanity to Institutions for the Insane. James Russell, Hamilton, Canada.
68 *Use of Intoxicating Liquors and Life Insurance. T. Millman, Toronto, Canada.
69 *Operative Treatment of Spina Bifida. E. R. Secord, Brantford.

68. **Liquors and Life Insurance.**—Millman makes the following deductions: 1. That total abstainers, other things being equal, are decidedly the best risks for life insurance. 2. That insurance companies are justified in accepting applicants who confine themselves to a glass of beer or wine, or a pony of whisky to each meal. 3. That such applicants, and those who take one or two glasses between meals should, if accepted, pay extra rates. As there is always danger that the habit will become more decided as time goes on, it is preferable that such applicants be rejected. 4. Those who get intoxicated for a few hours three or four times a year should also be rejected, as the habit is apt to increase. If accepted they should pay extra rates. 5. If more is consumed than in deduction 3, or of intoxication is more frequent and of longer duration than in deduction 4, the applicant should be rejected. 6. Officers and members of lodges should be careful in soliciting applicants who use intoxicating liquors. Medical examiners should carefully analyze the habit of each applicant in respect to the use of intoxicating liquors. They should not simply take the statement of the applicant, but ascertain just how much liquor he takes daily and what hours of the day. 7. As alcohol, taken to excess, damages the cells and the tissues of the body, care should be exercised in acting on the examination papers of applicants who state that one, or other, or both, of their parents were addicted to alcoholic excesses. The reproductive germs are damaged, and the health of the offspring, bodily and mentally, must be impaired. As a rule, they are not long-lived, and many criminals, idiots, etc., come from this class.

69. **Treatment of Spina Bifida.**—Secord believes that there are no absolute contraindications to the operative treatment of spina bifida. The worse the case the more marked becomes the futility of other than operative measures, and the greater the probability that the child will die if left alone. Paralysis, hydrocephalus and marasmus, often spoken of as contraindications, should not be so considered. Each has been and may be

improved. Absolute asepsis, combined with as little handling of nerve tissue as is essential, will give the best results. Loss of cerebrospinal fluid in moderate amounts is not of importance, neither is it necessary to operate on an inclined plane. The use of bony flaps is rarely, if ever, essential.

2. **Local Analgesia.**—Barker describes his method of producing local anesthesia. He uses B-eucain, which is far less dangerous than cocain, while possessing analgesic properties little, if at all, inferior to it, and with the concurrent use of adrenalin for the purpose of securing a retardation of circulation equivalent to constriction of the part, he has removed some of the objections as to the duration of the analgesia, the extent of the area which can be dealt with and the amount of the toxic drug to be employed. It is necessary to within the safe dose of the drug, and to have at our dis- a large enough quantity of the fluid medium to ren- possible to spread the analgesic agent over large areas. dinary surgical work Barker finds the following solu- answer well: Distilled water, 140 c.c.; B-eucain, 0.2 sodium chlorid, 0.8 grams; 1 to 1,000 adrenalin chlorid 10 minims. All this quantity of fluid can be used dinary case if necessary and is quite sufficient for Twice as much may be injected without ill results. ation of the insensibility is secured by the admixture adrenalin. Without it sensation is only abolished by for about fifteen minutes; with it, for three to four But the analgesia is produced more slowly when is employed with the eucain. It is therefore well larger operations to wait some thirty minues after to allow time for the insensibility to become fully d. After this the effect appears to deepen for a of hours. Waiting has another advantage. When alone is employed the operation must be done at once. sues are still in a state of artificial edema which the anatomic details unpleasantly. By adding adren- the eucain solution and waiting, the artificial edema isappeared and details are very clearly seen. Rapid on is to be avoided; sudden distention of the tissues greeable, if not painful. The fluid should not be used or too hot, for the same reason. All dragging on the is to be avoided, lest structures be pulled upon which eyond the area of infiltration. Barker has never seen depressing effects follow the use of B-eucain in a long s of operations. A list of operations done under B-eu- analgesia is appended, and among these are the fol- ng: Abdominal sections, hernia operations, amputations, hidectomy, removal of cyst of thyroid, removal of silver re from around the patella, operations for fistula in ano, ricose veins, hydrocele, varicocele, etc.

5. **Treatment of Thrombosis of Superficial Veins of Leg.**—Moullin excises, at the very earliest opportunity, the whole thrombosed portion of the vein with the most excellent results. The wound is healed in a week and the patient can get up cured and freed from all the risks of embolism, deep thrombosis, or recurrence. He has not found that a moderate degree of inflammation makes any difference. It begins to subside as soon as the offending vein is removed; but, of course, in such a case, the wound should not be sewed up tightly, as there is sure to be a considerable amount of oozing afterward.

15 Note on a Case of Acute Cerebral Abscess. A. L. Whitehead, Leeds.

8. **Congenital Intestinal Atresia.**—Two cases of this kind are reported by Clogg. The first was a female infant, aged 6 days. She had passed nothing by rectum and had passed very little urine. Vomiting commenced shortly after birth and persisted in increasing severity, becoming dark brown in color and very offensive. The navel was very prominent—a congenital umbilical hernia. At the necropsy it was found that the large intestine commenced just below the hepatic flexure; the transverse colon, sigmoid flexure and rectum were very shrunken. In the sac of the hernia was the lowest coil of small intestine, from which a diverticulum arose. Beyond this point the intestine which represented the cecum and ascending colon was much contracted; it was too small to permit of the onward passage of contents. The intestine ended blindly in the sac and the large intestine commenced just below the hepatic flexure of the colon. The second patient was a male infant, 4 days old. Shortly after birth he commenced to vomit, the vomitus becoming very offensive. The abdomen was distended. Nothing had been passed by rectum. Operation disclosed that the intestine ended blindly at the lower end of the ileum and was continued on as an impervious cord about half an inch in length into a much shrunken and contracted large intestine. The obstruction was situated about two inches above the ileum.

9. **Intravenous Injection of Diphtheria Antitoxin.**—In the course of nine months Biernacki and Muir treated 38 cases of diphtheria by intravenous injection of antitoxin. These cases are primarily grouped as nasopharyngeal, pharyngeal and laryngeal. In the first group there are 14 cases, with no deaths. In 5 cases intravenous injections only were used; in 6 cases relatively small supplementary doses were given by the subcutaneous method; in 2 cases both methods were equally employed, and in 1 case the greater part of the antitoxin was injected subcutaneously. Of pure pharyngeal cases there were 12, with 1 death. The administration of antitoxin was solely intravenous in 2 cases, mainly intravenous in 5, about equally intravenous and subcutaneous in 2, and chiefly subcutaneous in 3. The laryngeal cases fall into 3 groups—those not requiring operation, those intubated and those in which tracheotomy was performed. In the first group there are two ordinary cases, both ending in recovery. One was treated wholly and the other chiefly by the intravenous method. In a third case the lesion was mainly pharyngeal and nasal, but there was slight laryngeal involvement. It proved fatal. Six cases required intubation only, and all the patients recovered. In 4 cases the treatment was purely intravenous, in 1 mainly so; in the remaining case an equal subcutaneous dose was given. Tracheotomy was performed in 3 cases, with 1 death. In 1 all the antitoxin, and in a second half of it was given intravenously; in the third the intravenous dose was subsidiary. Two brands of serum (A and B) were employed in a previous series of 7 cases, 5 of which resulted fatally. Serum A was previously in use for hypodermic injection, and, when given intravenously, in 3 cases out of 4, it caused, within a short time, a varying degree of chill, pyrexia and circulatory depression. With neither serum was there any aggravation of the rash or of other later effects. In this second series of 38 cases only serum B was employed. The dose intravenously was 20,000 units. In the

entire series there was a fatality of 3 in 38 selected severe cases, a result which seems to favor the intravenous method. However, there has been a general fall in the fatality of diphtheria in the particular district cared for by the authors, and this leaves room for speculation as to whether the subcutaneous method might not have yielded better results. Nevertheless, it will be noted that of 9 cases operated on only 1 died. The authors conclude that even in cases other than laryngeal it seems very difficult, if not impossible, to say of any individual patient that a better result was obtained than might have followed subcutaneous injection.

11. **Relation of Epilepsy to Convulsions in Children.**—Moon urges that a serious view be taken of all convulsions occurring in infancy, and says that we are not justified in supposing that even a single convulsion in childhood will end with itself and have no further evil influence on the life of the child. For most of the cases which arise in connection with an extrinsic cause also have a history of heredity or alcoholism in the parents which are both predisposing causes of epilepsy. Even where there is no such history, and it is assumed that a peripheral irritation is adequate in itself to produce a convulsion in a perfectly normal brain, the mere fact of the convulsions being often repeated makes the brain cease to be normal and creates a distinct pathologic basis for the production of epilepsy. It is impossible to give the precise relation of such convulsions to epilepsy, but Moon believes that a much greater difference is made between these two affections than the facts seem to warrant.

13. **Unusual Case of Diaphragmatic Hernia.**—Newham's patient fell to the ground, a distance of some thirty feet, fracturing the left femur through the middle third and bruising the chest and abdomen considerably, but without signs of any fracture of the ribs. He was also vomiting and in a generally collapsed condition. Some dullness was made out in the flanks which shifted on moving the patient. A diagnosis was made of probably ruptured spleen, but owing to the general grave condition of the patient operative interference was out of the question. There was considerable pain over the cardiac region, somewhat increased on taking food. Later he was suddenly seized with most severe pain in the abdomen, accompanied by dry retching and intense thirst. The symptoms continued more or less severe for two days, when the patient suddenly became unconscious and died in about half an hour. On removing the chest wall at the autopsy, the first organ to present itself to view was the stomach, accompanied by part of the transverse colon, both greatly distended, and the latter showing signs of strangulation. These practically filled the left side of the thorax except for about ten ounces of blood-stained fluid which were present. The left lung was firmly pressed back against the spinal column, it was quite airless, small and deeply pigmented. The heart was healthy, though small and pushed over well to the right of the sternum. The right lung was small, congested and completely bound down by pleuritic adhesions. On examination of the diaphragm, an opening slightly to the left of the middle line, with smooth edges and easily admitting the index finger, was found, through which the stomach and intestines had escaped into the thoracic cavity. The hole in the diaphragm appears to have been made at the time of the accident and was probably caused by sudden, violent muscular contraction.

Semaine Médicale, Paris.

16 (XXIV, No. 51, December 21.) *De l'ostéotomie pubienne par la méthode de Gigli. R. de Bovis (Rheims).

16. **Extramedian Symphyseotomy.**—De Bovis makes out the balance sheet in regard to Gigli's "lateral section of the pelvis." He finds that the operation has been performed in 48 cases to date, and, with the exception of Baumm, all those who have performed it are much gratified with the results, both immediate and remote. Baumm's 2 patients died from infection resulting from laceration of the vagina. He does not give the particulars, and it is possible that the operation may not have been responsible for the fatalities. But even assuming that it was, this mortality of 2 in 48, or 4 per cent., is much less than the mortality of at least 10 per cent. after ordinary symphyseotomy. In every case the wound healed by primary intention. In De Bovis' 2 cases the callus was minimal and finally absorbed, so that a physician would not find a trace of the intervention on palpating the region or by digital examination through the vagina. The posterior articulations of the pelvis should be stretched beforehand to prevent pains later. The other indications are the same as for any symphyseotomy.

17 and 18. **Mechanical Dilatation with [illegible] Bossi's Dilator.**—Ehrlich states that not a single instance o[illegible] any noticeable complication of the puerperium, due to the u[illegible] of Bossi's dilator, was observed in 30 cases of eclampsia. [illegible]chanical dilatation should be reserved for serious cases, but [illegible] when indicated, it can be used without dread of complications. [illegible] 100 pages are devoted to the particulars of its application [illegible] at Leopold's clinic, with analysis of 70 articles on the subject [illegible] from the literature. Heller relates the details in 30 cases of contracted pelvis in which artificial premature delivery was accomplished with the Bossi, followed by the metreurynter. He emphasizes the importance of frequent external examination of the woman to watch the development of the fetal head during the last two months and that the child should not be taken out of the incubator too soon.

19. **Spinal Analgesia in Obstetrics and Gynecology.**—Stolz summarizes his conclusions on this theme as follows: Injection of .05 gm. tropacocain in 5 c.c. of cerebrospinal fluid is sufficient to induce analgesia in the external genitalia for an hour. The labor contractions are not reduced in frequency, length or intensity, but rather become more vigorous. The reflex action of the abdominal muscles is excluded, but voluntary action is possible and efficient. Spinal analgesia is suitable for operative intervention, but lumbar puncture is not so easy as in the nonpregnant subject. Spinal analgesia gave negative or dubious results in 2 cases of eclampsia. He reviews the particulars of 155 gynecologic and 25 obstetric cases in which it was applied. With only from .05 to .08 gm. of tropacocain the procedure is harmless. The larger the dose the longer and deeper the analgesia, while the larger the amount of cerebrospinal fluid used to dilute it, the greater the extent of the analgesia. A good rule is to use as many c.c. of the fluid as cg. of the tropacocain. In about 56.3 per cent. of the cases of laparotomy it gave sufficient analgesia for the purpose. About 31 per cent. required a little inhalation narcosis to complete the operation, and in 12.7 per cent. the spinal analgesia proved entirely inadequate and had to be supplemented at once by inhalation narcosis. A very small amount of the anesthetic answers the purpose in these circumstances. He has derived the impression that nervous affections and inflammatory processes seem to affect the spinal analgesia unfavorably.

30. **Radical Treatment of Rectal Cancer.**—Küpferle reviews 238 cases of rectal cancer treated by radical extirpation at Czerny's clinic during the last twenty-five years. About 36.4 per cent. of the patients were women. He states that 17.3 per cent. of the 196 patients operated on several years ago have remained well. This result was obtained in several cases in which the extent of the lesion rendered the outlook very unfavorable. The material is analyzed in detail and compared with the reports from other clinics.

37. **Febrile Luetic Cholecystitis.**—Riedel ten years ago had an opportunity to observe a case presenting the typical clinical picture of cholecystitis due to impaction of a gallstone in the neck of the gall bladder. An operation revealed merely thick bile in this organ, with adhesions connecting it to the duodenum and omentum. Fresh deposits of fibrin on the liver indicated that there must have been some recent and violent inflammatory process nearby. The liver contained a number of grayish nodules in the right lobe, unmistakable evidences of lues. This assumption was confirmed by the subsidence of all symptoms following the use of potassium iodid. The patient was a woman of 52 with no knowledge of a syphilitic infection, but who had 2 illegitimate children. In 2 other cases the syphilitic nature of the cholecystitis without icterus was recognized, but the pains were so intense that an operation was undertaken. It disclosed extensive adhesions and changes in the liver in both cases. The patients still have pains at times. In another case a febrile syphilitic process in the liver simulated cholecystitis. The patient was a physician of 37 and the intermittent colics with evening temperature of about 38 C., persisting for months, did not interfere with his practice nor debilitate him. Empyema of the gall bladder was his own diagnosis, and he clamored for an operation. A simple incision showed that this was a mistake, but the symptoms permanently subsided afterward. Syphilis of the liver is not rare, but it is frequently unrecognized. The patients generally belong to the upper classes, have consulted many authorities, and their disturbances have usually been ascribed to gallstones, or to cancer. One of his patients had been taking a course of treatment for a supposed inoperable cancer of the stomach; 6 bottles of potassium iodid caused a disappearance of all symptoms. Riedel has encountered only one serious case of acute cholecystitis *sine concremento*. All the others ran a harmless course. In another instance a child of 3 succumbed to an acute infection of the smaller biliary passages, originating in the papilla, with an abscess above the liver communicating with the pleural cavity. This case confirms the possibility that a perfectly healthy liver may become so infected that an abscess results without the presence of stones or of any lesion in the liver, and without any general constitutional disease. Several other unusual cases are described, among them that of a woman with febrile periods, icterus, liver dullness 18 cm., no tumor, no albuminuria, and not a trace of pain. The authorities discarded the idea of gallstones, but incision disclosed a large stone in the bile duct and pus in the gall bladder, the liver comparatively sound.

38. **Influence of Roentgen Rays on Internal Organs.**—Heineke's research on mice, rabbits, guinea-pigs and dogs has confirmed the statements of others in regard to the action of the Roentgen rays on the internal organs. The effect observed is entirely independent of that noted on the skin. With the exception of the testicles, the deep action of the Roentgen rays seems to be exclusively restricted to the organs concerned in the making of blood. The action is manifested in two ways: in the annihilation of the lymphoid tissue and in the destruction of the cells of the bone marrow and spleen pulp. This reaction of the lymphoid tissue is specific. It occurs long before any other organ or system of organs shows any changes from the exposure, and the dosage can be calculated to limit the action of the rays to this tissue alone. The reaction is further distinguished by the lack of any latent stage, by its sudden onset, its stormy course, its early termination, the absence of any after-effects and by the rapid restitution of what has been destroyed. In all these points the reaction is directly the reverse of what is observed in regard to the action of the Roentgen rays on other material. We must always reckon with this destruction of the lymphocytes as an inevitable accompaniment of any exposure. It does not seem to entail any undesired or dangerous by-effects.

42. **Tumors in the Groove Between Pons and Medulla.**—Funkenstein draws the clinical picture of a tumor in the recess between the pons, cerebellum and medulla, as illustrated in a number of cases. He asserts that tumors at this point are operable only when they are solitary and unilateral. Bilateral tumors are operable, but they are generally associated with a more or less extensive central neurofibromatosis. Unilateral deafness is an important sign of a unilateral tumor, usually solitary. Sternberg's is the only case on record in which it was associated with multiple tumors. When the deafness is bilateral and a tumor on both sides is probable, and with them central neurofibromatosis, the chances of an operation are far less favorable. As these tumors are of very slow growth, the life expectancy is actually lessened by any surgical intervention. The surgeon's hand may be forced, however, by the importunity of the subject begging to be released from his annoying symptoms. The article is a very complete study of the subject, based on 6 cases and 10 from the literature. The first of the writer's patients died after an operation by Krause's technic, the findings indicating central neurofibromatosis. The second patient succumbed unoperated on. A solitary neurofibroma was found on the right auditory nerve. A solitary neurofibroma involving the auditory and facial nerves on one side, with psammoma of the dura, was found in the cadaver of an elderly woman who had died from peritonitis. The fourth case was one of sarcoma in the cerebellum, the fifth of endothelioma in the left posterior fossa, both fatal. The symptomatology of each of the cases is carefully reviewed. Gibson's is the only one on record cured by operation, and the diagnosis of "acoustic neuroma" was dubious in this case.

44. Complicating Nephritis in Appendicitis.—This article from Bäumler's clinic emphasizes the seriousness of nephritis as a complication of appendicitis. It describes a case of acute hemorrhagic nephritis, the onset coinciding with that of appendicitis. The kidney affection gradually subsided as the other grew worse. Hildebrandt is convinced that he saved his patient only by refraining from operating on the appendix until the kidneys were able to functionate better by the subsidence of the nephritis. The cases on record in which operative treatment was undertaken—regardless of the concomitant nephritis—all terminated fatally. Complicating nephritis, therefore, modifies somewhat the indications for surgical treatment in appendicitis.

45. Triple Invagination in an Infant.—Riedel illustrates a case of triple invagination in a 5 months old infant. The ileum had become invaginated through the ileocecal valve into the cecum, while at the same time there was retrograde invagination of the sigmoid flexure in the descending colon, and the lower end of the sigmoid flexure had become invaginated in the rectum. Conditions were restored to normal by a laparotomy, but the child succumbed to an immediate double pneumonia. The abdominal viscera were found apparently quite normal at the necropsy.

47. Fatigue Toxin and Antitoxin.—Weichardt is convinced that he has established the fact that the functioning muscles of warm-blooded animals form a toxin which can be separated by dialysis from the ordinary chemically definable products of disassimilation. Injection of this fatigue toxin into other animals induces the symptoms of extreme fatigue, torpor and death, the same as in animals succumbing to the effects of physical overexertion. This fatigue toxin is not found in the carcasses of unfatigued animals, and other animals injected with their muscle plasma are unaffected by it. The fatigue toxin has the properties of a true toxin, and injected in sufficient amounts causes the production of an antitoxin. This antitoxin differs from the bacterial antitoxins by its extreme stability and by the readiness with which it dialyzes. This explains the facility with which it is absorbed in the *digestive tract. It thus displays properties which adapt it* for therapeutic use as a restorative and invigorant.

49-50. Technic of Agglutination Test.—Stäubli gives illustrations of a "mixing block," etc., by which the agglutination test is simplified. He takes up a tiny drop of blood in a pipette and then fills the rest of the pipette with physiologic salt solution, centrifugalizing this mixture instead of the serum alone. Much less blood is required than by the ordinary technic. He thinks microscopic examination of the agglutination is indispensable. Tiling merely draws the blood on a scrap of blotting paper and dissolves it out again at his leisure with physiologic salt solution. Neither of the above writers regard the presence of the blood corpuscles as detracting from the accuracy of the test.

53. Suggestion and Temperature in the Tuberculous.—Köhler advises a sham injection before the true tuberculin test, to eliminate the influence of suggestion as far as possible. He also advises an occasional sham injection in the course of systematic tuberculin treatment, for the same reason. Tuberculous subjects should be guarded against emotions and moral impressions liable to raise the temperature by suggestion. A positive response to a tuberculin injection should not be estimated from the increased temperature alone, but from the general condition and changes in the local lung findings.

55-56. Roentgen Treatment of Leukemia.—Schenck's patient treated with the x-rays for severe lymphatic leukemia was only symptomatically benefited. She was 53 years old and had noted the spleen tumor for seven years. The spleen diminished in size and the leucocytes became less numerous, but the reds *also diminished in numbers* and the symptomatic improvement did not seem to retard the progress of the disease. In another case of acute leukemia the leucocytes dropped spontaneously during the week before death from 76,000 to 3,000. In the case treated with x-rays about 35 exposures of the spleen and sternum were made, the former for from 5 to 10 minutes, the latter only 4 or 5. The spleen showed no change during the first 20 exposures, but then rapidly diminished in size. Cahen reports the case of a man of 47 whose spleen was hard and so large that it almost filled the entire abdominal cavity, extending a hand breadth beyond the umbilicus on the right and above to the costal arch. The blood findings were 1 to 40. After 22 exposures to the x-rays the findings were 1 to 1,073 and the spleen had subsided until it was no longer accessible to palpation. The general health improved to correspond. The long bones were then exposed to the rays and at present, after 40 exposures in all, the patient has just been dismissed but with the understanding that constant surveillance will be necessary to maintain what has been accomplished. The exposures were from 8 to 15 minutes long, the tube hard and at a distance of about 25 cm. The leukemia had been first noticed one year before treatment was commenced.

60. Permanent Pessary Thermometer.—The advantages of a permanent thermometer in the rectum which allows the readings to be made without removal of the thermometer or without disturbing the patient, are obvious to every physician. Oertmann's illustration shows the form he recommends. It is of the same shape and size as an ordinary hemorrhoidal pessary, the mercury being in the bulging end inserted in the rectum. The maximal reading is thus obtained without disturbing the patient. The thermometer could also be made in the shape of or to be attached to an ordinary vaginal pessary.

61. Improved Nipple for Nursing Bottles.—Schmidt describes a hard rubber nipple which absolutely prevents the entrance of air into the nursing bottle, except when desired. It is also possible to regulate the amount of milk the child is getting by adjusting the nipple to regulate the negative pressure in the bottle after the infant has been sucking for a time. He thinks that this nipple approaches the ideal closely. The principal features are a roll of rubber on the inside of the nipple which prevents its being pulled over the neck of the bottle beyond a certain point. One side of the nipple below this roll is slit nearly to the roll. When the negative pressure in the bottle has reached a point where sucking becomes hard, the mother twists the nipple a trifle while the child is still sucking, and thus allows a little air to enter.

67. Surgical Treatment of Inguinal Buboes.—Hermann treated 61 cases of bubo consecutive to hard or soft chancre by injection of a 10 per cent. glycerin emulsion of iodoform. About 8 per cent. were completely cured in less than four days; 31 per cent. in five days; 26 per cent. in six days, and a duration of from nine to ten days was observed in less than 8 per cent. He first evacuates the pus through a minute incision and then fills the cavity with the emulsion. As it is forced out by the pressure of the surrounding parts, he fills the cavity again two or three times, leaving it distended with the emulsion.

68. **Stature of the Japanese.**—Nakamura's statistics sustain the assumption that the physique of the Japanese is advancing with the progress of the nation in general. The data cover the period of eleven years ending in 1902. An average of about 400,000 recruits were examined each year. The proportion of those 5 feet 4 inches or more in height has steadily increased from 10 to 12.67 per cent.; of those 5 feet 1.7 inches in height the proportion has increased from 31.84 to 35.06 per cent., while of those under 5 feet in height the proportion has dropped from over 20 to 16.20 per cent.

70. **Idiopathic Gangrene.**—Kojima reviews the occidental literature on this subject, and states that five Japanese monographs, with microscopic findings, have also been published. Haga's was based on 10 cases, all in males from 27 to 47 years old; Watsuji's on 5 male cases and 1 female case, the ages 31 to 48, and Tanaka's on 3 cases of gangrene of the foot and 1 of the thumb. Kojima's personal experience has included 2 cases in men, aged 44 and 48 respectively. The microscopic findings are those of sclerotic thickening of the intima of the artery and occasionally of the vein, with secondary thrombosis extending upward or downward from the area of thickening, entailing the occlusion of the vessel. The arteriosclerosis does not differ materially from ordinary arteriosclerosis, except that the subjects are younger. The gangrene is probably induced, he thinks, by predisposition, certain mechanical or chemical factors and others which produce sclerosis of the vessels. The left side is affected more frequently than the right, and males more than females. The process may run a chronic course or it may develop suddenly. Amputation is imperative when gangrene has begun, otherwise symptomatic treatment is indicated, with mercury if there is any suspicion of syphilis. (See Stevens' article in THE JOURNAL, Dec. 31, 1904, page 2033.)

71. **Percussion Outline of the Lungs.**—Takata gives diagrams of the boundaries of the lungs as determined by percussion of healthy subjects. His findings differ in several respects from those taught in the text-books.

72-73. **Carbon Dioxid Intoxication Cause of Beri-beri.**—Ashmead presents evidence to show that the charcoal braziers used all the year around in Japanese houses are the cause of beri-beri. They generate carbon dioxid, which is the more injurious from the custom of sleeping on the floor. The Chinese have beri-beri when they burn charcoal, but when they burn other fuel there is no beri-beri.

74. **Central Scotoma in Kakke.**—The central scotoma in the case described preceded the other symptoms of the kakke It was transverse elliptic in both eyes, as also the scotoma for colors. The eye findings corroborate the theory of a toxic polyneuritis as the essence of kakke.

75. **Causes of Cancer.**—Sata describes considerable experimental research which has not given any conclusive results, although suggesting the probability of a parasitic etiology. He calls attention to some of the questions to be solved before serum treatment can be practicable. Is the so-called cancer serum capable of destroying only the cancer cells, or will it simultaneously injure the normal epithelial cells which a alike in their histogenic structure, or will it not affect th cells in such vital organs as the kidneys, liver, etc.? His experiments failed to demonstrate such a specific action on certain cells with absence of action on others, as is affirmed by some French investigators. The kidney cells seem to suffer most from the action of these cytolytic sera.

85 *The Limits of Hearing Capacity.—Die Grenzen der Schwerhörigkeit. V. S. Stein (Copenhagen).

78. **Weak Heart with Mitral Defects.**—Stein's clinical experience and experimental research have conclusively demonstrated, he thinks, that the chronic insufficiency of the heart in case of a mitral defect may be due to chronic infection as well as to a functional disturbance of the heart's energy. Chronic myocarditis existed in only 4 of his 13 cases, and in none of Romberg's 7, while it was dubious in one of those reported by Krehl. The danger from a rheumatic valvular defect does not lie in the possibility of chronic myocarditis—resulting from the primary rheumatism, but rather in the relative or absolute extent of the valvular defect, and in the possibility of acute or chronic reinfections.

80. **Chloroform Intoxication Per Os.**—The symptoms in the case described had their counterpart in those exhibited by rabbits after ingestion of chloroform. The patient had swallowed from 20 to 30 c.c. of chloroform. Of 47 cases recorded in the literature 28 recovered. In 11 of the fatal cases consciousness was never regained.

81. **Current Medical Literature of the Scandinavian Countries.**—The *Nordische med. Archiv* makes a specialty of very complete and reliable abstracts of all the articles published in the current periodical literature of Norway, Sweden, Denmark and Finland. The abstracts are all in German, with the original titles in full and also translated. A complete oversight of the literature of the Northland is thus afforded every one who can read German. The literary output is extensive and valuable.

82. **Treatment of Invagination.**—In 1893 Wichmann published a monograph on this subject, and now brings it down to date. He groups the statistical material in a number of instructive tables, etc. In the adult, non-operative treatment is rarely successful. Invagination occurs more frequently in the small intestine. When the colon and ileum are involved—which occurs in from 45 to 55 per cent. of the cases—reduction is impossible. Fully 45 per cent. of the total invaginations were accompanied by complications. Early primary laparatomy is the standard procedure, but he warns that it is necessary to examine the patient again in the narcosis before using the knife, as in several cases spontaneous reduction had occurred at the last moment, and, at the laparotomy, the conditions were found normal. The material reviewed includes 1,184 cases. Of the 1,049 cases in which the age was mentioned, 502 were infants, 194 were between 2 and 10, 166 between 10 and 30, and 187 over 30. In the 502 infants only 4 cases are known of total expulsion of the invaginatum. If there is incarceration, operative treatment is the only resource. Opium or morphin generally has a favorable effect in infants, as it checks the progress of the invagination, although it prevents spontaneous reduction. If a good surgical clinic is

at hand the practitioner should send the infant there at once, not even attempting any examination in narcosis, leaving this to the surgeon, as also the decision whether to use the knife or not. In the absence of a good surgeon the practitioner should remember that non-operative treatment of quite recent cases is apt to be successful, but by the second or third day such measures are liable to be dangerous and rarely cure. Manipulations, artificial distension of the large intestine with air or fluids, are liable to cause harm when the intestine has suffered from two or three days or more of invagination. The distension should be moderate and kept up for about ten minutes at a time. Hirschsprung states that these measures proved successful in 37 out of 64 children under 7 in his experience. All with invagination in the small intestine or ileocolon died. The greatest difficulty with these bloodless measures is that it is almost impossible to tell whether reduction has been accomplished or not. The tumor may subside, the bowels move several times, and yet the invagination may still persist to a slight extent and gradually assume its former proportions. Or the tumor and constipation may persist after the invagination has been completely reduced. The temperature generally rises even after reduction. The uncertainty is, therefore, great, and laparotomy is the preferable procedure in favorable surroundings. Even when the physician thinks that the reduction is complete, it is well, if possible, to place the infant in the surgeon's care for surveillance and operation, if necessary.

83. **Suppuration in Tendon Sheaths of Palm.**—Forssell reports 92 cases of tendovaginitis and bursitis and describes his method of treatment applied since 1897. The results are most excellent, compared with those obtained by other technics. He became convinced that the almost inevitable necrosis observed in cases of acute suppurative bursitis of the palm is due mainly to the great pressure exerted by the ligamentum carpi. He established further that no functional harm resulted from slitting this ligament. The action of the hand and fingers was not interfered with in the least by so doing. Consequently treatment should aim to open up the field of infection as early, extensively and as completely as possible. His series of 63 cases thus treated shows the great superiority of the measure and the fine results attained, with the absence of the mutilations formerly noted. The article is accompanied by 15 plates showing the topography of the parts, the technic and the results.

84. **Cephalocele of the Orbit.**—Stadfeldt reports a case of pulsating exophthalmus which he assumed to be a cephalocele of the posterior orbit. He gives the particulars of the 28 similar cases he was able to find in the literature. All except Holmes' case are of European origin. Seven terminated fatally; in 4 after an operation. Two of the others were complicated with hydrocephalus or deformities. In the present case the exophthalmus could be transformed into enophthalmus by pressure on the eye, paralleled by slowing of the radial pulse at the same time. The pulse dropped from 84 to 68, without any brain symptoms. Compression of the left common carotid reduced the pulsation considerably, and there was no nausea. No abnormal murmur was heard and the tension of the eyeball was normal. The pulsation was permanently reduced by ligation of the carotid near the crico-thyroid ligament, and the ptosis of the lid was much relieved by lateral tarsorrhaphy. The ligation of the carotid evidently modified the circulation in the brain and reduced the amount of fluid in the cephalocele, thus inducing great improvement, permanent for a few months to date, at least. The retrospective diagnosis of cephalocele orbitæ posterior was based on the congenital origin, the soft tumefaction, the asymmetry of the skull in general, the presence of coloboma iridis on the same side, and the slight mental and moral apathy displayed by the patient, a young woman, whose speech was rather indistinct, although she appeared to be well developed and healthy.

85. **The Limits of Hearing Capacity.**—Stein insists that a distance of 100 cm. for the whispered voice is not enough of a test for the hearing. Male artisans should be able to hear the whispered voice at 200 cm., while the range should be from 300 to 700 cm. for public or other functionaries. School children, physicians, musicians and midwives should hear the whispered voice at a distance of more than 700 cm. His article is an attempt to show that the hearing capacity required as the standard in certain occupations may be far above or below the standard required in others. He remarks that housewives can get along with a minimal standard of 150 cm. When the size of the room does not allow a test beyond a certain distance, he adds + to the figure representing the distance.

Books Received.

Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from these volumes will be made for review, as dictated by their merits, or in the interests of our readers.

Original Articles.

THE NATURE AND SIGNIFICANCE OF LEUCOCYTOSIS.*

A. MANSFIELD HOLMES, M.D.
DENVER, COLO.

When Cohnheim demonstrated that inflammation and suppuration are due to an emigration of the white corpuscles, a great advance was made in pathology. Since then the importance of the white blood corpuscles has been increasing with each year.

CELL TYPES.

If leucocytes consisted of but a single variety of cells, with common functions, the study of leucocytosis would be reduced to a simple process. It would then be sufficient simply to ascertain the degree of leucocytosis by estimating the total number of leucocytes to a cubic millimeter of blood.

It is well known, however, that the white blood corpuscles consist of several more or less distinct varieties. Many attempts have been made to differentiate these types, resulting in not a little confusion in the nomenclature thus introduced.

1. A classification has been based on the nature of the behavior of the cells to microchemic reagents, giving us acidophile, basophile and neutrophile cells.
2. Another has been based on the form and number of nuclei, giving us small and large mononuclear, transitional, polymorphonuclear and polynuclear forms.
3. A third classification has been made in accordance with the supposed origin of each type, giving lymphocytes, splenocytes, myelocytes and mast cells.
4. The nature of the granules has given us a fourth classification, non-granular, finely granular and coarsely granular cells.
5. A classification according to functions would probably be most useful if we knew more of their subtle nature. The functions of these small organisms are so obscure that such a classification must be left for further research to perfect. Metchnikoff, however, has made the nearest approach to a classification according to this method that has yet been attempted, and has brought to our notice phagocytes and non-phagocytic cells.

LACK OF UNIFORM STANDARDS.

In addition to a lack of uniformity in the classification of leucocytes, the relative percentages accepted as normal for each type have been given a comparatively large range of variation. There has also been a lack of uniformity among hematologists in the technic adopted. Many staining methods are in vogue, varying materially in their ability to reveal the characteristics of the cell elements, which further increases the difficulty in properly classifying cells. By adopting a definite technic uniform morphologic characteristics are revealed; a true picture of each cell type is formed, and a correct classification of leucocytes becomes an easy task.

(A) VARIATION OF THE CELL TYPES IN HEALTH.

Two factors govern the number of cells belonging to the various cell types in health as well as in disease: (*a*) The total leucocyte count, and (*b*) the relative percentages for the cell types.

Under changing conditions the normal leucocyte count may vary from 5,000 to 10,000 cells for each c.mm. of blood. These estimates are accepted as the minimum and maximum normal counts.

In health, the upper and lower percentage limits are moderately well established for each cell type. The following minimum and maximum normal percentages for the respective cell types may be accepted as representing the normal percentage range: Small lymphocytes, 22-30; large lymphocytes, 5-9; transitionals, 1-2; polymorphonuclears, 60-70; eosinophiles, 1-2.

The differential percentages taken alone are of little clinical value. It is only when the total leucocyte count is considered in connection with these percentages that the number of cells belonging to the respective cell types can be approximately estimated.

To estimate the cell variation for the respective cell types for normal blood, the calculation is made on the basis of the minimum and maximum normal leucocyte count (5,000-10,000), each count accompanied by the minimum and maximum differential percentages for each cell type. To illustrate, an estimate of the number of small lymphocytes will be made in accordance with these standards.

(*a*) The minimum normal leucocyte count (5,000), accompanied by the minimum differential percentage (22 per cent.), will place the minimum normal small lymphocyte count at 1,100 cells for each c.mm. of blood; the same count, accompanied by the maximum differential percentage (30 per cent.), will establish the maximum normal small lymphocyte count at 1,500 cells.

(*b*) The maximum normal leucocyte count (10,000), accompanied by the minimum differential percentage (22 per cent.), will place the minimum normal small lymphocyte count at 2,200 cells; the same count, accompanied by the maximum differential percentage (30 per cent.), will establish the maximum normal small lymphocyte count at 3,000 cells.

Therefore, according to these standards, any actual lymphocyte count that is included within these normal extremes (1,100-3,000) may be considered as falling within normal limits.

The following table gives the normal range of the cell count for each cell type, based on the foregoing normal standards:

---

* Read in the Section on Pathology and Physiology of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

TABLE 1.

	S.L.	L.L.	Trans.	Poly.	Eos.
Minimum and maximum differential percentages for each cell type..	22-39	5-9	1-2	60-70	1-2
Minimum and maximum number of cells for each cell type estimated from the minimum normal leucocyte count (5000).	1100 1500	250 4350	50 100	3000 3500	50 100
Minimum and maximum number of cells for each cell type, estimated from the maximum normal leucocyte count (10,000).	2200 3000	500 900	100 200	6000 7000	100 200

To account for the wide normal variation of the number of cells for the various cell types, as shown in Table 1, we must consider:

1. Causes which affect the actual number of leucocytes.
2. Causes which affect the relative percentages for the various cell types.

First Factor.—It seems to be fairly well established by clinical data that the total leucocyte count varies in health according to the conditions of nutrition. Healthy and vigorous individuals furnish a leucocyte count near the maximum normal limit. On the other hand, persons in feeble health, with poor digestion and assimilation, and weak resisting power, generally furnish a leucocyte count near the minimum normal limit. Consequently, under certain conditions of nutrition, a leucocyte count of 5,000 may be considered normal, while under other metabolic conditions a count of 10,000 is normal.

Second Factor.—The wide normal range for the actual number of cells belonging to the respective cell types may be further explained on the ground that in certain apparently normal individuals the minimum differential percentage is present for certain types, such a condition always being accompanied by a corresponding relative increase in the percentage of certain other types. (*a*) This percentage reciprocity is almost always found to exist between the small lymphocytes and the polymorphonuclear cells; (*b*) it may, however, exist between the small lymphocytes and the large mononuclears.

It at once becomes apparent that the percentage reciprocity so often found in cell type study exists between a non-phagocytic *cell type and some one or more of the* phagocytic types.

The prevailing tendency, when there is a deviation from the normal percentages, is a fall in the small lymphocyte percentage. A low small lymphocyte percentage may result from various causes:

(*a*) From some cause which diminishes the actual number of small lymphocytes, without being accompanied by any apparent change in the total leucocyte count.

(*b*) From an increase in the leucocyte count, without being accompanied by any material change in the actual number of small lymphocytes.

(*c*) From causes which produce both a decrease in the actual number of small lymphocytes and an increase in the total leucocyte count.

To observe the relation which these respective conditions bear to the physical state of the patient, and to ascertain if these relations possess any significance as to the state of the resisting power, are problems which should receive our closest attention.

It is apparent that with a small lymphocyte count near the minimum normal limit (1,100), accompanied by a leucocyte count close [illegible] the maximum normal limit (10,000), the relative percentage of small lymphocytes will fall to 11 per cent. Furthermore, that with a small lymphocyte count near the maximum normal limit (3,000), accompanied by a leucocyte count close to the minimum normal limit (5,000), the relative percentage of the small lymphocytes will rise to 60 per cent. Therefore, *if the normal* range for the actual number of small lymphocytes lies between the extreme limits of 1,100 and 3,000 cells, and if the normal range for the total leucocyte count lies between the extreme limits of 5,000 and 10,000, the possible relative percentage limits for the small lymphocytes will fall between 11 per cent. and 60 per cent.

The following table shows the relative percentage variations for a definite cell type count (small lymphocytes), when *accompanied* by a varying leucocyte count:

TABLE 2.

	Minimum leucocyte count, 5000. Per cent.	Average leucocyte count, 7500. Per cent.	Maximum leucocyte count, 10000. Per cent.
Minimum small lymphocyte count—1100	22	14.66	11
[1]Average small lymphocyte count—1950	39	26	19.5
Maximum small lymphocyte count—3000	60	40	30

These facts make it imperative that we should not depend on relative percentages alone, but that we should ascertain the actual number of cells belonging to each cell type if we hope to correctly interpret the relations existing between cell types, or if we hope to ascertain the true relations which the cell types bear to the body or to its inherent vital forces. Relative percentage fluctuations are affected by any influences which call for phagocytic action on the part of the cells.

AVERAGE NORMAL STANDARDS.

For practical work it is necessary to adopt definite average normal standards. For this purpose 7,500 is generally accepted as the average normal leucocyte count. And for average normal relative percentages those suggested by Kanthack have been adopted, viz.: Small lymphocytes, 26 *per cent.;* large *lymphocytes,* 7 per cent.; transitionals, 1 per cent.; polymorphonuclears, 65 per cent.; eosinophiles, 1 per cent.

This table shows the cell count for each cell type, estimated from the foregoing average normal standards:

TABLE 3.

	S.L.	L.L.	Trans.	Poly.	Eos.
Average normal leucocyte count 7500.					
Average normal differential percentage for each cell type......	26	7	1	65	1
Average normal number of cells for each cell type................	1950	525	75	4875	75

(B) VARIATION OF THE CELL TYPES IN LEUCOCYTOSIS.

For our present purpose, leucocytosis will be interpreted as an increased functional activity of the body cells. This phenomenon exists normally within narrow limits in connection with the digestive process and other physiologic activities.

The many changes which take place in the food products from the time they are introduced into the body until they are rendered suitable for cell food are the result of cell activity. The processes of life seem to come and go in rhythmic cycles. A period of rest follows a period of activity; each period of activity is again followed by rest. This is apparently a universal law. To live, an organism must eat. If it eats, it must work. If it works, it must rest. Time has been divided in accordance with this principle. Day and night, the seasons of the year, are evidence of the rhythmic cycles of life.

Digestive leucocytosis is but the evidence of this law, revealed in cell phenomena. Whatever the mode of activity or the cause of the activity, this law is found to exist. Whenever the law is broken, from whatever cause, a disequilibrium of the co-operative functions of the body is a natural result. The continuance of this resultant inharmonious relation between the co-operative functions brings about a transition from a normal to an abnormal state—a transition from health to disease.

---

[1] For the average normal standards see Table 3.

Every organism, however, is endowed with an inherent tendency to obey this law, and resists any and all influences which tend to interfere with its action. The principle of self-preservation and self-protection, as universally revealed in living organisms, are but manifestations of the law of the rhythmic cycles of action and repose.

Pathogenic micro-organisms are cell foes. When they gain an entrance into the animal organism they at once antagonize, not only the fixed but the wandering cells of the body. They interfere with the normal cycle rhythm of cell life. The result is an increased and prolonged cell activity without normal quiescent states. The evidence of this constant cell activity is revealed in a continuous leucocytosis, a leucocytosis which often passes far beyond the bounds of a normal physiologic leucocytosis.

To correctly interpret a leucocytosis, one must consider the nature of the factors producing the disequilibrium of cell functions. It is but natural, therefore, that we should inquire into the nature of the cell changes found in leucocytosis, as well as the causes producing them.

It is equally important to ascertain if definite relations exist between these cell changes and the life potential of the larger organism.

The nature of the cells supplied, when an organism reacts in its own defense, may have more significance than we are inclined to give them. It can scarcely be questioned that distinct and independent functions belong to each of the cell types. It is important, therefore, to ascertain to what degree each cell group cooperates in an effort at organic self-protection.

It is generally conceded that most importance is attached to the cell types whose increase chiefly constitutes a leucocytosis. The impression prevails that the most significant cell phenomena in leucocytosis are confined to the polymorphonuclear variety. In recent studies I have been impressed with phenomena belonging to the small lymphocyte group; although not marked by such pronounced extremes as are observed in the polymorphonuclear types, they at least seem to convey a weightier significance.

It is conceded that the cell types owe their origin to distinct and independent sources. This being accepted, it would be but a natural step to infer a definite relation between these cell types and the cell-generating organs producing them.

The following tables show distinctly that the great bulk of cell increase in leucocytosis belongs to types possessing phagocytic power, namely, the large mononuclear, transitional and polymorphonuclear forms. These varieties possess the power of locomotion to a marked degree and are able to englobe foreign bodies.

The sudden and often profound increase in these varieties can not, therefore, be attributed to an increased functional activity of the organs producing these cells. On the other hand, their sudden disappearance as leucocytosis subsides can not be attributed to cell lysis, since the evidence of cell death and the débris of disintegrating cells is absent.

The sudden appearance and disappearance of the cells constituting leucocytosis must, therefore, be explained on other hypotheses. The most probable explanation for the sudden and profound variation in the number of cells should conform to the very nature of these cells—based on their ability to migrate to and fro from the circulating blood, to cling to the walls of the blood vessels, and to retire to and move from the deeper organs of the body.

Their presence or absence in the circulating blood, above or below the number normally found in this medium, would, therefore, seem to be governed by the presence or absence of certain imperfectly understood chemotactic influences. In reality, it can not be claimed on any means of interpretation at our command that the actual number of cells belonging to the phagocytic types found in the circulating blood in leucocytosis bears any significant relation to the state of the organs producing them, their great numerical variation depending largely on their ability to migrate.

This, however, can not be affirmed of the other cell types not included in the phagocytic forms, namely, the small lymphocytes and the eosinophiles. The eosinophile cells are frequently entirely absent when a crisis exists in the organism sufficient to produce a leucocytosis. These cells possess the power of locomotion and may pass to other regions for specific purposes. It has been claimed on good authority, however, that during the existence of a profound infection the eosinophile cells lose their granules, which cause them in turn to lose their identity. This fact makes it difficult to establish a definite relation between the actual number of eosinophiles in the circulating blood and the state of the organs producing them, or the organism as a whole.

This leaves but one other cell type to be considered—small lymphocytes. Small lymphocytes are not endowed with the power of locomotion to any definite degree, nor the power of englobing foreign bodies. These cells, therefore, can not in any degree be considered phagocytic.

Their number in the circulating blood, therefore, can not be increased or diminished by means of any inherent power possessed by the cells themselves. They are present in large or small numbers as a result of the functional activity of the organs producing them. There seems, therefore, to be good reason for assuming a significant relation between the actual number of these cells in the blood and the state of the cell-producing organs recognized as their source.

By most authorities small lymphocytes are recognized as young cells. Cell genesis being one of the most potent and one of the most important functions of an organism, it is naturally inferred that the state of this function sustains an important relation to the resisting power of the organism.

The following study has been made for the special purpose of ascertaining the possible existence of a definite relation between the number of young cells in the circulating blood and the inherent resisting power of the patient. The clinical material thus far accumulated has not been sufficiently extensive, nor the time sufficiently long, to enable the formation of mature and positive deductions.

The differential count of the small lymphocytes in leucocytosis is almost always relatively decreased. This accounts for the statement frequently made that their actual number is decreased. I was also of this opinion until I began to estimate the actual number of cells belonging to the various cell types in health and disease.

Having collected a series of cases in which inflammatory leucocytosis existed, it became apparent that, although the relative percentage of the small lymphocytes is always reduced, their actual number frequently remains close to normal, and occasionally is found considerably increased.

In another set of cases in which leucocytosis existed, it was observed that, although the leucocytoses were well marked, the actual number of small lymphocytes to each c.mm. of blood was greatly reduced, often falling far below the minimum normal limit. It was soon recognized as a significant fact that the cases belonging to the latter class were critically ill, and often terminated fatally. This led to a more extended study of cell types for the purpose of ascertaining their diagnostic and prognostic significance.

The following cases are reported for the purpose of comparing the clinical histories with the blood changes accompanying them. The blood chart accompanying each case records the date of each blood study, accompanied by the leucocyte count, the relative percentages and the actual number of cells belonging to each cell type. Following the blood charts and clinical histories, each case is taken up separately with an attempt to interpret the associated cell type phenomena.

Case 1.—Mrs. C. W. E. Appendicitis.

Date.	White cells.	S. L.	L. L.	Trans.	Polymor.	Eos.
April 13, 1898	30,600	5	11	3	81	0
		1,530	3,366	918	24,786	0
April 14, 1898	22,200	15	10	1	73	1
		3,330	2,220	222	16,206	222
April 16, 1898	9,400	24	14	3	58	1
		2,256	1,316	282	5,452	94
May 21, 1898	20,400	7	8	0	85	0
		1,428	1,632	0	17,340	0
May 22, 1898	15,700	15	13	2	70	0
		2,355	2,041	314	10,990	0
May 24, 1898	10,500	34	12	2	51	1
		3,570	1,260	210	5,355	105
May 25, 1898	9,500	48	12	0	39	1
		4,560	1,140	0	3,705	95
May 28, 1898	8,400	41	7	0	51	1
		3,444	588	0	4,284	84
June 3, 1898	7,900	41	5	0	53	1
		3,239	395	0	4,187	79

History.—On April 8, 1898, the patient was seized with pain in lower abdomen, followed by chill, vomiting, tympanitis and fever; the pains centered in the right iliac region, but no palpable tumor could be detected. The symptoms continued until April 13, when a consultation was held. A blood study revealed a leucocytosis of 30,600. April 14, leucocytosis subsiding and symptoms abating. Improvement continued for one week. May 21, liberal diet allowed, followed by slight relapse. Steady improvement for two weeks.

Operation.—June 4. A chronically inflamed appendix found, bent at a right angle and bound down by an adhesion. Drainage had taken place into the intestine. At the angle of constriction the appendiceal wall had sloughed almost to the point of perforation. Another acute attack would probably have resulted in perforation and general peritonitis. Patient made rapid recovery.

Case 2.—Mr. J. E. H. Appendicitis.

Date.	White cells.	S. L.	L. L.	Trans.	Polymor.	Eos.
March 29, 1898	22,700	10	7	1	82	0
		2,270	1,589	227	18,614	0
March 30, 1898	17,200	12	7	1	80	0
		2,064	1,204	172	13,760	0
April 1, 1898	11,700	25	8	1	65	1
		2,925	936	117	7,605	117
April 4, 1898	17,300	13	13	0	73	1
		2,249	2,249	0	12,629	173
April 5, 1898	18,400	10	7	2	81	0
		1,840	1,288	368	14,904	0
April 6, 1898	17,500	15	9	0	76	0
		2,625	1,575	0	13,300	0
April 18, 1898	9,000	28	8	9	54	1
		2,520	720	810	4860	90

History.—Symptoms developed much the same as in Case 1. After numerous consultations doubt remained as to the nature of the trouble. A blood study finally revealed a leucocytosis of 22,700, which at once excluded typhoid fever.

Treatment.—The expectant plan of treatment was adopted. Daily blood studies were made and the clinical symptoms carefully watched. A good recovery followed without operation.

Case 3.—Mr. S. N. C. Appendicitis.

Date.	White cells.	S. L.	L. L.	Trans.	Polymor.	Eos.
Dec. 5, 1898	23,000	10	6	0	83	1
		2,300	1,380	0	19,090	230
Dec. 6, 1898	25,000	5	4	0	90	1
		1,250	1,000	0	22,500	250
Dec. 7, 1898	19,700	Differential count not made.				
Dec. 8, 1898	16,300	Differential count not made.				
Dec. 10, 1898	14,800	8	10	0	80	2
		1,184	1,480	0	11,840	296

History.—In this case the trouble was recognized as appendicitis from the beginning. Patient's previous health had been impaired. Operation advised, but refused.

Treatment.—Expectant plan of treatment followed. The leucocytosis slowly subsided, but with each day the patient's strength seemed to be diminishing. Slow recovery without operation.

Case 4.—Miss H. Appendicitis.

Date.	White cells.	S. L.	L. L.	Trans.	Polymor.	Eos.
Oct. 22, 1903	28,000	5	4	1	90	0
		1,400	1,120	280	25,200	0

History.—Patient treated for typhoid fever. At the expiration of two weeks, the symptoms being somewhat unusual, a blood study was requested, which revealed a leucocytosis of 28,000.

Treatment.—Patient immediately sent to hospital and operated on. Perforated, gangrenous appendix found and a large quantity of pus diffused throughout the abdominal cavity. Speedy recovery followed.

Case 5.—Mr. H. D. Appendicitis.

Date.	White cells.	S. L.	L. L.	Trans.	Polymor.	Eos.
July 30, 1897		5	5	0	90	0
Aug. 2, 1897		4	6	2	88	0
Aug. 4, 1897	47,500	7	5	1	87	0
		3,325	2,375	475	41,325	
Aug. 5, 1897		5	4	0	91	6

History.—The symptoms were obscure from the beginning, resembling in some respects both typhoid fever and appendicitis. A surgeon was called early in the attack and remained in attendance. Frequent examinations failed to reveal tenderness or induration in region of appendix.

Blood Examination.—The prevailing opinion favored typhoid until August 2, when blood films were taken, a study of which indicated a distinct leucocytosis. A second differential blood count gave evidence of a distinct leucocytosis. On August 4 a third blood study revealed a leucocytosis of 47,500. A careful examination at this time revealed a deep-seated tenderness in the right pelvis posteriorly, near the spine.

Treatment.—An immediate operation was suggested, but refused by the family. Consent was finally given and operation performed thirty-six hours later. A retroverted appendix with extensive gangrene and perforation, with large quantities of fecal pus in abdominal cavity, told the story which the leucocytosis had foretold six days before. Death speedily followed operation.

Case 6.—Mr. J. H. S. Convalescent tuberculosis.

Date.	White cells.	S. L.	L. L.	Trans.	Polymor.	Eos.
March 21, 1898	18,200	15	13	2	50	20
		2,730	2,366	364	9,100	3,640
March 28, 1898	8,000	21	9	2	51	17
		1,680	720	160	4,080	1,360
Oct. 24, 1902		24	9	1	63	3

History.—Inflammatory leucocytosis developing in a tuberculous patient well advanced in convalescence, the result of a self-administered hypodermic injection of serum. Leucocytosis rapidly subsided. Patient continued to improve, and four years and six months later all evidence of the disease had disappeared.

Case 7.—Mr. A. T. C. Advanced tuberculosis.

Date.	White cells.	S. L.	L. L.	Trans.	Polymor.	Eos.
March 17, 1898	15,000	8	13	2	73	4
		1,200	1,950	300	10,950	600
April 1, 1898	10,500	14	10	1	71	4
		1,470	1,050	105	7,455	420

History.—Acute moderate leucocytosis similar to that observed in Case 6, and produced in a similar manner. This patient, however, was well advanced in tuberculosis. The patient failed rapidly and died six months later.

CASE 8.—Mr. J. L. G. Pneumonia associated with advanced tuberculosis.

Date.	White cells.	S. L.	L. L.	Trans.	Polymor.	Eos.
Oct. 20, 1900....		4	9	1	86	0
Oct. 22, 1900....		4	9	2	85	0
Oct. 23, 1900....	16,700	2	6	0	92	0
		334	1,002	0	15,364	0

History.—Patient in advanced stage of tuberculosis. After exposure pneumonia developed, with rapidly fatal termination.

CASE 9.—Mrs. F. E. S. Pyosalpinx.

Date.	White cells.	S. L.	L. L.	Trans.	Polymor.	Eos.
Jan. 12, 1903....	25,000	9	5	1	84	1
		2,250	1,250	250	21,000	250

		860	1,290	215	19,135	0
Jan. 28, 1903....	18,000	4	6	1	89	0
		720	1,080	180	16,020	0
Jan. 29, 1903....	14,000	5	3	0	92	0
		700	420	0	12,880	0
Feb. 2, 1903....	13,000	8	8	0	84	0
		1,040	1,040	0	10,920	0

History.—Patient gave a history of frequent inflammatory attacks, confined to region of right tube and ovary. Evidence of an acute attack developed about one week before date of first blood study, accompanied by clinical symptoms of increasing severity. On January 12 the following clinical picture was given: High fever, rapid pulse, occasional chills, severe pain; symptoms continued to increase until January 15, when operation was performed.

Right ovary and tube were seriously involved, but the inflammatory condition was apparently localized. January 19 to 21, slight evidence of reaction. January 22, symptoms indicating a very critical condition, which continued with no evidence of improvement. Patient died February 23, twenty-four hours after the last blood study.

CASE 10.—Mrs. U. H. B. Subacute pyosalpinx.

Date.	White cells.	S. L.	L. L.	Trans.	Polymor.	Eos.
May 13, 1904....	19,000	11	9	2	78	0
		2,090	1,710	380	14,820	0
May 17, 1904....	27,000	8	5	1	86	0
		2,160	1,350	270	23,220	0

History.—Frequent attacks of pelvic inflammation. At the time of the blood study the patient had been confined to her bed for several days. The right tube was involved and the pelvic organs were cemented in a solid mass. Resolution was rapid. Recovery without operation.

INTERPRETATION OF CELL TYPE PHENOMENA.

It becomes apparent, on inspecting the blood charts of the foregoing cases presenting leucocytosis, that in certain cell types the actual count shows a more or less pronounced decrease, while for certain other types the count shows a pronounced increase.

The types showing a decrease invariably belong to the non-phagocytic groups (small lymphocytes and eosinophiles), while the types showing an increase belong to the phagocytic groups (large mononuclear, transitional and polymorphonuclear).

The interpretations and deductions which follow are founded on the following premises:

(*a*) That a leucocytosis is the evidence of an effort on the part of an organism to protect itself.

(*b*) That the cells supplied in a leucocytosis belong chiefly to the phagocytic groups.

(*c*) That the small lymphocytes, being non-phagocytic cells, indicate the condition of the organism's defense, and therefore may serve as a means of estimating the ability of the organism to endure a severe or prolonged resistance. In other words, the leucocytosis indicates the fighting strength of an organism, and the number of small lymphocytes indicates the character of the endurance.

For the purpose of ascertaining the value of these cell type phenomena a brief review of the foregoing cases will follow. In making comparisons and interpretations it will be necessary to refer frequently to Tables 1 and 3.

Case 1, April 13, presents a well-marked leucocytosis (30,600), accompanied by a small lymphocyte count close to the average normal standard (1,530), indicating a severe infection and a strong resisting power. April 14, presents a diminishing leucocytosis (22,200), accompanied by a pronounced increase in the small lymphocyte count (3,330), passing above the maximum normal limit (3,000), indicating diminishing infection and an increasing resisting power. April 16, presents a leucocyte count close to normal (9,400), accompanied by a slight fall in the small lymphocyte count (2,256), but considerably above the average normal standard (1,950). April 21, again presents a moderate leucocytosis (20,400), accompanied by a reduced small lymphocyte count (1,425), indicating a relapse. May 22, to the end of the case history, presents a decreasing leucocytosis and an increasing small lymphocyte count, passing above the maximum normal limit, indicating a decrease of the infection and a marked increase in the resisting power. Verification: Patient made a good recovery after operation.

Case 2 presents a fluctuating leucocytosis of moderate degree, accompanied by a small lymphocyte count ranging,continuously between the average and maximum normal standard (1,950 to 3,000). Interpretation: Moderate infection and good resisting power.

Case 3, December 5, presents a well-established leucocytosis, accompanied by a small lymphocyte count above the average normal standard. December 6, slight increase in the leucocytosis and a distinct fall in the small lymphocyte count, indicating an increased infection and a diminished resisting power. December 10, diminishing leucocytosis and a small lymphocyte count close to the minimum normal standard, indicating a decrease in the infection, with a weak resisting power. Verification: Subsequent recovery after slow convalescence.

Case 4, October 22, presents a well-marked leucocytosis, accompanied by a moderately low small lymphocyte count. Interpretation: Infection moderate, resisting power good; verified by speedy recovery after operation.

Case 5, August 4, leucocytosis profound, small lymphocyte count high, infection severe, resisting power good. A blood study was not made after the infection became general, hence the state of the leucocytosis and the small lymphocyte count at this time is not known.

Too much emphasis can not be placed on the fact that the location and nature of the lesion should always be considered in connection with a leucocyte study. A leucocyte count ever so high, or a small lymphocyte count ever so great, will avail but little if the warnings they give are unheeded until the infection becomes so extensively spread that it has gone beyond the power of any leucocytosis to check, or the strongest resisting power to overcome. Except for the perforation in this case, which permitted the development of a general infection, the prognosis would probably have been favorable.

Case 6, March 21, presents a moderate leucocytosis, accompanied by a small lymphocyte count close to the maximum normal limit: Interpretation: Moderate infection, good resisting power; confirmed by ultimate recovery.

Case 7, March 17, presents a moderate leucocytosis, accompanied by a small lymphocyte count reduced close to the minimum normal limit. Interpretation: Moderate infection and feeble resisting power.

Comment: A comparison of Cases 6 and 7 reveals interesting facts. Both cases are accompanied by a moderate leucocytosis; Case 6 accompanied by a small lymphocyte count 780 above average normal, and Case 7 accompanied by a small lymphocyte count 750 below the average normal standard. The ultimate recovery of Case 6 and the rapidly fatal termination of Case 7 emphasize the significance of the small lymphocyte counts.

Case 8 presents moderate leucocytosis and very low small lymphocyte count. Interpretation: Profound sepsis, very feeble resisting power; case terminated fatally.

Case 9, January 12, presents a well-marked leucocytosis, accompanied by a small lymphocyte count above the average normal, indicating a severe infection and a moderate resisting power. As the case progressed, January 13 to 15, the leucocytosis increased and the small lymphocyte count diminished, indicating an increase in the virulence of the infection and a decrease in the resisting power. January 17, after the operation, the degree of leucocytosis diminished materially and the small lymphocyte count fell to a very low point. January 19 to 21, leucocytosis slightly increased, with distinct increase in the small lymphocyte count, indicating an effort to react. After January 21 the leucocytosis remained practically unchanged, but the small lymphocyte count again fell to a dangerously low point, with no apparent ability to react.

Case 10, May 13, presents a moderate leucocytosis, accompanied by a small lymphocyte count above the average normal standard; May 17, presents a distinct increase in the leucocytosis and a slight increase in the small lymphocyte count. Interpretation: Fighting strength and endurance good; confirmed by a speedy recovery.

RELATION BETWEEN THE SMALL LYMPHOCYTE COUNT AND LEUCOCYTOSIS.

The foregoing interpretations of the cell type phenomena presented in leucocytosis are based on the following possible relations between the small lymphocyte count and the degree and course of the leucocytosis:

A. The Relation of the Small Lymphocyte Count to a High or an Increasing Leucocytosis.—1. A high or increasing leucocytosis, associated with a high or increasing small lymphocyte count, indicates: (*a*) An infection of high or increasing virulency, accompanied by (*b*) a high or increasing resisting power.

2. A high or increasing leucocytosis, associated with a low or decreasing small lymphocyte count, indicates: (*a*) An infection of high or increasing virulence, accompanied by (*b*) a low or diminishing resisting power.

B. The Relation of the Small Lymphocyte Count to a Low or a Decreasing Leucocytosis.—3. A low or decreasing leucocytosis, associated with a high or increasing small lymphocyte count, indicates: (*a*) An infection of a low or decreasing virulence, accompanied by (*b*) a high or increasing resisting power.

4. A low or decreasing leucocytosis, associated with a low or decreasing small lymphocyte count, indicates: (*a*) An infection of a high or increasing virulence, accompanied by (*b*) a low or decreasing resisting power.

The actual number of small lymphocytes may be reduced to a very low point for a short period, but unless they soon show a tendency to materially increase in number, we must infer that the power to react has been exhausted. This observation seems to hold true notwithstanding the leucocytosis may remain at a very high point.

The resisting power of an organism is measured not so much by the degree of the leucocytosis as by the relation of the cell types to the leucocytosis (compare Cases 5 and 6).

It is probably true that each individual is a law unto himself as to his ability to respond in the production of a leucocytosis. The number of leucocytes held in reserve in the deeper tissues, ready to appear in a general call for co-operation, probably varies with each individual. The degree of leucocytosis necessary to protect any particular individual will depend on the nature of the infection. The infection may be too weak to stimulate a pronounced antagonism on the part of the leucocytes. On the other hand, it may be hypertoxic and paralyze the phagocytic or combative power of the cells. The nature of the infection, therefore, is a most essential factor in considering the development of the degree of leucocytosis. This will probably account for the existence of certain infections, without an attending leucocytosis, such as is found in typhoid fever and tuberculosis.

C. Variation of the Cell Types in Abnormal Blood States Unaccompanied by Leucocytosis.—Many important diseases are unaccompanied by leucocytosis, and yet the blood is characterized by pronounced cell type changes. Very little attention has been given to the observation of these changes with the purpose of interpreting their diagnostic or prognostic significance.

Important among the diseases unaccompanied by leucocytosis are typhoid fever and leucocytosis.

TYPHOID FEVER.

Cases 11 and 12 are typical typhoid cases, showing the relation of the cell types.

Case 11.—Mr. C. W. E. Typhoid fever.

Date.	White cells.	S. L.	L. L.	Trans.	Polymor.	Eos.
Oct. 15, 1903....	8,000	7	5	0	88	0
		560	400	0	7,040	0

This case presents a malignant form of typhoid in which intestinal hemorrhages developed, with final perforation and death. Blood study made at the end of the sixth week revealed a small lymphocyte count far below the minimum normal standard, indicating a state of exhaustion with no power to react, confirmed by a rapidly fatal termination.

Case 12.—Mr. A. M. P. Typhoid fever.

Date.	White cells.	S. L.	L. L.	Trans.	Polymor.	Eos.
Oct. 13, 1896....	8,500	12	15	0	70	3
		1,020	1,275	0	5,950	255

Blood study made at the end of the sixth week, when patient had already entered on convalescence. The small lymphocyte count registered near the minimum normal limit. Patient made good recovery.

The small lymphocyte counts, as shown in these two cases, become especially significant when interpreted in the light of subsequent results—the number of small lymphocytes in the convalescent case being double the number found in the case ending fatally.

TUBERCULOSIS.

Some eight years ago I became interested in the study of tuberculous blood. My attention at the beginning was confined chiefly to the morphologic appearance of the blood elements as revealed by special staining methods.

It soon became apparent that there was more than a chance relation existing between the percentages of the cell types and the actual condition of the patient. Preliminary reports have already been published on these earlier studies.[2]

After a lapse of these years and the accumulation of clinical material there has been ample opportunity to weigh the data and to arrive at deductions that should stand the test of time.

I wish to give a brief summary of 202 tuberculosis cases studied since my first report, whose subsequent histories have been followed to date. After a careful review of the blood records of these cases, accompanied by their histories as a guide to the interpretation, it became apparent that in almost every instance the small lymphocyte percentage was an accurate criterion of the real condition of the patient at the time the blood count was made. These cases have been divided into three groups, governed by the state of their small lymphocyte percentages.

---

[2] Med. Rec., Sept. 5, 1896; Med. Rec., Nov. 17, 1896; The Journal A. M. A., Oct. 23, 1897.

Class 1.—This includes all cases in which the small lymphocyte percentage went to 10 per cent. or lower. The subsequent histories of these cases have been carefully gathered, with the following significant results:

Apparent recoveries	1
Convalescent	8
Disease progressing	4
Deaths	56
Total	69

It should be especially noted that for the eight cases included as convalescents, and the single case of apparent recovery, the low small lymphocyte percentage was the exception. The low percentages in these cases were found when the patient first came to Colorado, or during a temporary relapse.

Class 2.—This includes all cases in which the small lymphocyte count was never found to pass above 20 per cent. or below 10 per cent. It should be noted that only a single blood study was made for a number of cases included in this class. Had repeated studies been made, higher counts would no doubt have been found in those showing apparent recovery or marked convalescence, and lower counts in those terminating fatally, or in which the disease advanced. Results to date:

Apparent recoveries	3
Convalescents	11
Disease progressing	7
Deaths	32
Total	53

Class 3.—This includes all cases in which the small lymphocyte count was found at any time to pass above 20 per cent. Results to date:

Apparent recoveries	39
Convalescents	15
Disease progressing	4
Deaths	22
Total	80

For the 22 fatal cases in this class the high small lymphocyte count was exceptional in 12; three made marked improvement and died suddenly of pneumonia as a result of exposure; two made rapid improvement and relapsed after assuming heavy business responsibilities before convalescence had been well established, and one died as the result of an operation.

CELL TYPE PHENOMENA IN TUBERCULOSIS.

(*a*) Well advanced tuberculous cases, or cases belonging to any stage of the disease, with feeble resisting power, give a low small lymphocyte count.

(*b*) Tuberculous patients well advanced in convalescence always show an increasing small lymphocyte count.

DEDUCTIONS.

A. Significance of a Low Small Lymphocyte Count.—(*a*) A gradual decrease in the small lymphocyte count is unfavorable. (*b*) When repeated examinations, extending over a long period, give a continuous low small lymphocyte count, an unfavorable prognosis is indicated. (*c*) A prevailing low small lymphocyte count, with an occasional higher count, indicates a temporary effort toward convalescence, with little chance for permanent recovery. (*d*) A gradual increase in the small lymphocyte count, with an occasional low count, indicates an uncertain convalescence.

B. Significance of a High Small Lymphocyte Count.—(*a*) A gradual increase in the small lymphocyte count is favorable. (*b*) When repeated examinations, extending over a long period, give a continuous high small lymphocyte count, a favorable prognosis is indicated.

It may be taken, therefore, as a safe conclusion: 1. That poverty in small lymphocytes exists in connection with a great impairment in body nutrition and cell metabolism. 2. That this condition exists in typhoid fever, tuberculosis, and a variety of debilitated conditions. 3. That it can not, therefore, be interpreted as being characteristic of any particular disease. 4. That whenever it exists it is always to be considered a potent factor when estimated in connection with the history of the case and the associated clinical symptoms.

On the other hand, the lymphocytosis that so frequently accompanies a well-marked convalescence, from a condition in which poverty of lymphocytes previously existed, would seem to indicate a condition of increased physiologic activity, thus corroborating Virchow's theory of a nutritive and formative hyperacidity of a convalescent organism.

205 Jackson Block.

CHRONIC ARTERIAL HYPERTENSION.*

HENRY WIREMAN COOK, M.D.
Visiting Physician, Memorial Hospital.
RICHMOND, VA.

The renewed interest in blood pressure, from a medical point of view, and the succession of articles by clinicians appearing on the subject, crowned by Janeway's book just off the press, indicate that the question is proving of more than scientific value, and that it is becoming an established element in diagnosis and treatment. The activity in this direction has necessarily been coincident with and limited by the development of practical methods for accurately estimating this symptom, and as these methods come more and more into general usage, the value of their application and the interpretation of the data derived therefrom will gradually assume their rightful position in the collective symposium of each carefully reviewed case. Two years ago, while resident at the Johns Hopkins Hospital, I emphasized the necessity for an accurate estimation of arterial tension, not only in the laboratory and in the especially desperate cases in hospitals and in operating rooms, but in the routine examinations of the general practitioner. At the same time I offered a simple modification of the Riva Rocci principle in the form of a compact portable instrument that could be conveniently used in office or visiting practice.[1]

One phase of this question is now claiming special attention. and has lately been prominently exploited by Dr. Clifford Allbutt,[2] Dr. J. H. Broadbent and Dr. Alfred Stengel, namely, the relation of arteriosclerosis to pulse tension and a differential classification of the former based in part on this relation.

With the advent of accurate clinical methods of studying pulse tension the many problems involving these conditions, which so long have been confused and obscure, are now being gradually elucidated.

The insufficiency of tactile impressions for the recognition of tension is responsible for this confusion, which will be eliminated in time by the application of exact and comparable standards of measurement. The result of this indefinite knowledge has been especially unfortunate, as it has given but slight recognition to the large group of cases which is, from a clinical standpoint, the most important, because most amenable to treatment. This group consists of those cases in which the only manifested sign of disease is an increased arterial tension, without or previous to the development of the organic changes, which alone the clinician usually recognizes as "nephritis" apoplexy, arteriosclerosis or myocarditis. It is true that in practically all these cases a certain degree of cardiac hypertrophy exists, but before the onset of dilatation this hypertrophy may be very difficult of recognition. It is with this class that my paper has principally to do.

---

* Read in the Section on Pharmacology of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

[1] This instrument I continue to find most satisfactory, now made with a 9 cm. arm-piece. This and the instruments of Stanton and Janeway are the only sphygmomanometers manufactured in this country. It is to be hoped that other instruments will be successively perfected in order to hasten the general adoption of accurate methods for the estimation of this symptom.

[2] Allbutt: Trans. Royal Med. and Chir. Soc., London, 1903.

Dr. Allbutt divides arteriosclerosis clinically from the view-point of etiology, into three classes: First, involutionary, common in old people, not necessarily dependent on high tension; second, mechanical, the result of long persistent high-blood pressure; third, toxic, resulting from lead or alcohol poisoning, or from syphilis; this form usually occurs in young persons with or without accompanying hypertension.

Primarily, I would insist on an absolute distinction between arteriosclerosis and hypertension. Arteriosclerosis is a pathologic change of tissue for which the physician has no remedy. Arterial tension is a cardiovascular function, the perversion and abnormalities of which the diagnostician can now recognize and should attempt to correct. What Dr. Osler says of cirrhosis of the liver applies to sclerosis of the blood vessels: "Many writers speaking of the curability of certain forms show a lack of appreciation of the essential condition on which the symptoms depend. So far as we have any knowledge, no remedies at our disposal can alter or renew the cicatricial connective tissue which constitutes the materia *peccans* in ordinary cirrhosis."

If we relieve a case of arteriosclerosis, with a vasodilator, we do not alter the amount of fibroid degeneration, we merely correct the hypertension, which may either bear a causal relation to the arteriosclerosis or may be associated with it merely as a distinct manifestation of a mutual causative condition. The value of an accurate and discriminating knowledge of this relationship and association between the organic change in vessel structure and the functional perversion of vascular tension is apparent when we consider that the latter is very amenable to treatment, and is a most potent factor in the production of the former incurable condition, as well as the train of other cardiovascular diseases.

Arteriosclerosis is really a pathologic condition, and has too long overshadowed and been confused with a correct recognition of hypertension as a distinct clinical entity. The more chronic hypertension is emphasized, and the more its presence is detected and its destructive tendencies corrected, the sooner will a large and increasing class of cases be brought under proper treatment; cases that now often are neglected until the kidneys pass albumin, the heart dilates, or a cerebral vessel ruptures. Only 12 per cent. of Broadbent's 16 cases of apoplexy showed senile degeneration of the cerebral vessels; the other 88 per cent. probably depended in greater part for their fatal termination on hypertension, not simply as a complicating or concomitant symptom, but as the underlying causative factor.

Almshouses and asylums afford in the subjects of senility excellent opportunities for the study of arteriosclerosis, and I have to thank the officers of those institutions in Richmond for permission to use the material. Here the arterial changes are often reflected by the poorly nourished brain in a weakened mental condition. Such an arterial alteration frequently persists for years, even at the age of 65 or 70, with an unenlarged heart, or, indeed, with cardiac atrophy, without albuminuria, and with fair general health. Apoplexy is not especially frequent in such cases, which are most typically represented by old women in whom tobacco, alcoholic nephritis, syphilis and overwork do not so frequently complicate the picture. The arterial tension does not usually exceed 140 or 160 mm. Hg, and this is not allowing for the 10 or 15 plus mm. of pressure necessary to compress the sclerosed artery. At postmortem, the arteries of both systemic and cerebral vessels may be in places so calcified as to break in the fingers; instances are not infrequent in these cases of such interference of circulation as to induce dry gangrene of an extremity. These patients may undergo a serious amputation, or perhaps several, and may live for years.

Let us consider quite a different group, typically represented by a large robust-looking man in active successful business life. He may be between 45 and 55, temperate as to alcoholic indulgence, and eats, as he says with some pride, three or even four large meals a day. He is readily accepted for life insurance, and the examiner probably adds in his zeal some complimentary additional remark to the fact that the applicant is an unusually fine specimen. Yet in from two to five years that man may be waterlogged and exhibit embryocardia, or his family physician is surprised to find albumin in the urine, or else without warning he may suffer a stroke of apoplexy, or some evening acute dilatation after dinner may demand payment of the policy. Postmortem, the arteries, excepting a few slight areas of degeneration in the aorta, some dilatation of the cerebral vessels, and more or less hypertrophy of the media in the systemic vessels, are normal. If it is quite true that a "man is as old as his arteries," why should this man die of vascular disease at 50, and another live with pipe-stem arteries for several decades past 60? As a matter of fact, the most extreme grades of arteriosclerosis and calcification are frequently found in those who have outlived the allotted time of man, and who finally die of old age or of a secondary infection, and do not seem particularly prone to fatal forms of vascular disease. Of course, where the sclerosis involves the valves of the heart, the case is quite different, and here the sclerosis, by inducing insufficiency, is the immediate cause of the progressively downward sequence. Further, except in the localized disease of syphilis or during the weakened transition period of beginning degeneration, the thickened vessels of advanced sclerosis do not seem especially to lack resistance, as evidenced, for instance, by the incidence of aneurismal formation.

Hence we must look farther than the arterial wall, *per se*, or the heart, for the primary etiologic factor in many of these cases of early cardiovascular failure. In an examination of a number of cases, there is one symptom which is common to them all; when removed, it is followed by improvement; it increases *pari passu* with the progress of the disease; when artificially increased, it renders the disease worse. This symptom is hypertension, and it thus fulfills the requirements of a causal agent. Some of these patients have sclerosed arteries, but not the majority; some pass albumin in the urine, but only a few; yet all will register a pressure over 160 mm. Hg, and many over 180 mm. Hg.

Furthermore, we know the members, especially the males, of certain families, inherit a tendency toward the early development of this class of cardiovascular and renal disease, and for several generations two-thirds of the males may die before 60 of Bright's disease, apoplexy or heart disease. The members of such families almost invariably show more or less marked hypertension long before any organic lesion is made manifest.

The hypertensive diathesis, if I may use such an expression, is far more clear-cut and definite a condition than the strumous or uric-acid diathesis, of which we hear so much, and it should be so recognized. We can not estimate the tendency to tubercular disease nor to gout, but we can accurately determine the degree of hypertension, and what is better, follow year by year its progress and regulate its tendencies. We are not correct, then, in saying that a "man is as old as his arteries," but we can, I believe, usually prophesy that, other things being equal, longevity will be in inverse proportion to pulse tension.

Broadly speaking, of course, we may not divide organic from functional disease, as we must believe that there always exists some fundamental alteration in structure to account for every functional derangement. However, in the present indefinite state of our knowledge concerning the molecular alterations in living protoplasm, we may still be permitted, for the sake of clearness, a division which later researches may prohibit. In considering the possible underlying causal factors which produce this perversion of function, we find they fall under four main headings, which suggest a clinical classification of chronic hypertension from an etiologic standpoint, as follows: First, arteriosclerosis; second, cardiac, pulmonary, and cerebral compensatory; third, toxic; fourth, primary.

Necessarily, where such a classification of a chronic condition is attempted, the divisions will frequently overlap where more than one causal element is concerned in any fully developed case; for once given a disturbance of function, it may disorder the normal function of other organs, which, in turn, react on the primary condition. Nevertheless, this is the most fruitful method of studying a non-specific disease from a practical clinical point of view, as a recognition of the proper causal agents in any one case gives the only clue toward rational treatment. Thus etiology, though perhaps not admitting such absolutely distinct divisions, is a better basis for clinical classification than symptomology, pathology or empirical therapy.

Arteriosclerosis seems in some cases, perhaps especially in those where the small arterioles are involved, to cause a rise in tension through increased peripheral resistance. In the cases where the larger vessels are markedly affected, there may be no rise in tension.

For many years Dr. Allbutt and Dr. Broadbent alone have opposed the view that nearly all cases of hypertension fall under this head. Dr. Allbutt's classification is distinctly of arteriosclerosis, and must not be confused as representing hypertension. In going over the cases in the Richmond almshouses, few of the examples of advanced sclerosis showed a pressure over 160 mm. Hg, and one case, presenting probably the most advanced sclerosis of any seen, had a pressure in the brachial of 120 mm. Hg. The radial artery seemed to the touch as though made of quill, and was circled by marked ridges and rings. This woman was over 70, and is still active, though her mental condition showed marked senile weakening. The arteries in this case were not tortuous, but almost straight. This calls attention to distinction between actual degenerative sclerosis and the bending and thickening of the artery due to hypertension.

Many marked cases of sclerosis show no tortuosity at all, but, on the other hand, cases with persistent high-blood pressure, almost invariably show bending of the artery, with thickening of the walls, and this may be independent of any marked evidence of sclerosis. Where there is both bending and sclerosis, it would seem probable that this bending had occurred primarily from hypertension, and that the sclerosis had followed as secondary degeneration. It is not by any means correct, then, to consider all thickened tortuous arteries as examples of arteriosclerosis, as is so frequently done. As a matter of fact, early sclerosis seems to prevent marked tortuosity, as one would naturally expect from the relative elasticity of sclerosed and of normal artery wall.

I believe that many cases of thickened tortuous arteries, which are spoken of as cases of arteriosclerosis, are in reality cases of hypertension, with consequent hypertrophy and stretching of the wall, just as the heart hypertrophies and dilates, and that the presence of sclerosis should be considered an independent complicating condition rather than an essential factor. That hypertension favors and may even induce the development of arteriosclerosis, is unquestioned, but to designate every case of thickened bent arteries as an example of arteriosclerosis is a mistaken diagnosis, based on the not infrequent error of taking a resulting condition as the primary factor, especially where the true causal agent is not easily determined.

By the aid of more accurate clinical observation on pulse tension and on arteriosclerosis, I believe the latter will be found to occupy a much less important position in diagnosis and in prognosis than it obtains at present, and that the former will assume more and more of the responsibility of the various symptoms and terminal complications that are now credited to arteriosclerosis. According to my observations, cases of marked hypertension do not usually live long enough to develop a very high grade of arteriosclerosis.

The blood vessels of the brain are frequently unable to withstand rupture by hypertrophy, the heart is apt to dilate, or the kidneys to suffer serious damage, and this before the arterial degeneration has assumed an advanced condition.

The prognosis, in the case of a robust-looking man of 55, with a blood pressure of 200 mm. Hg, even with no arteriosclerosis, is not so good as in the case of a man of 65, with marked sclerosis and a blood pressure of 130 mm. Hg. The former is in daily danger of apoplexy or of cardiac dilatation, while the latter lives along year after year apparently unchanged.

The source of danger in the former case is not primarily the thickened artery or the arteriosclerosis, as the condition is frequently spoken of, but the hypertension. The thickened artery is a physiologic development for self-protection, rather than a source of danger, just as is the cardiac hypertrophy in a case of aortic insufficiency. If the heart and arteries are able to meet the demands of the hypertension, they may endure the additional strain for years. So that, though we must give hypertension a prominent place in the etiology of arteriosclerosis, and conversely arteriosclerosis must be credited as a causal element in many cases of hypertension, the two conditions frequently interacting in a vicious circle, nevertheless we should carefully distinguish the one from the other.

Another group comprises those cases in which hypertension is dependent on cardiac hypertrophy, either from chronic muscular overexertion or from valvular disease, or on pulmonary obstruction, or cerebral compression. Cardiac hypertrophy is a necessary complication of hypertension; they interact on one another, each augmenting the other. But there are definite cases in which the chronic condition of hypertension depends immediately on the enlarged heart, although the hypertrophy was originally produced by a temporary hypertension, dependent on transitory causes. For example, athletes and wornout pugilists almost invariably exhibit, previous to the final cardiac breakdown, a marked hypertension dependent on the enlarged heart, when they may have taken no violent exercise for years. There may be no sclerosis and no toxemia. The cardiac hypertrophy is merely the result of a physiologic response to the repeated temporary increase of tension from excessive physical exercise in earlier years, but sustains a chronic hypertension.

Ordinary laborers are subject to this form of hypertension. In these cases the engine has become too powerful for the rest of the machinery, which is gradually wrecked and destroyed, merely by the constant throbbing and pounding. Very large individuals are more prone to cardiac hypertrophy than the average, as the work to be accomplished is greater. Other similar cases are where the heart hypertrophies from some other temporary need for increased force, such, for instance, as a vasoconstrictor or cardiac stimulating toxin acting for sufficient period to produce hypertrophy and then being withdrawn ceases *per se* to be an immediate causal factor. From our knowledge of the temporary action of the drug, and without sufficiently prolonged clinical observation to justify a positive statement, we may suppose that prolonged use of digitalis, with its subsequent withdrawal, might present such a condition. Overindulgence in tobacco, apparently, induces cardiac hypertrophy. In the monograph by Dr. Briggs and myself, in a recent volume of The Johns Hopkins Hospital Reports, mention is made of the influence of tobacco in raising blood pressure, and it is there suggested as a causal factor in arteriosclerosis. Janeway confirms this observation. Further observation inclines me to the belief that tobacco does not primarily affect the arterial wall injuriously, but where sclerosis is induced, it is done indirectly through the induction of increased tension. I have found that many young men who smoke to excess uniformly exhibit hypertension ranging from 160 to 180 mm. Hg, and I have lately met with several cases of hypertension and cardiac hypertrophy in older men where the only etiologic factor obtainable was excessive indulgence in tobacco.

Alcohol has no such action. It is not a cardiovascular stimulant, and does not produce hypertension. As a factor in the production of hypertension, alcohol must act either indirectly by causing sclerosis of the arterial wall, as it apparently acts on the liver in cirrhosis, or else through the medium of a toxin produced by some metabolic disorder which the alcohol may have induced. This secondary toxin may either act as a vasoconstrictor, as is probably the case in alcoholic nephritis, or may directly injure the arterial walls. The alcohol itself does not act by inducing hypertension. In the production of cardiovascular disease, independent of a primary nephritis, I believe that the importance of alcohol has been exaggerated and that of tobacco relatively underestimated.

In compensated valvular insufficiencies, accompanied by cardiac hypertrophy, there is chronic hypertension at systole, even though the back-flow may induce a low diastolic pressure.

Certain cases of chronic pulmonary disease, such as emphysema, chronic fibrous changes and asthma, in which more or less obstruction to the pulmonary circulation probably occurs, are associated with high-tension pulse. Sansom is the authority for the suggestion that a chronic consolidation of a lung with high-tension pulse is probably not tuberculosis, at least in an active form, as that disease is constantly accompanied by low tension.

Certain cases of cerebral tumor produce a condition of hypertension in the systemic arteries, in order to prevent anemia of the vital centers.

In still other cases certain toxins induce hypertension by a constricting action on the arteries, either directly or through the vasomotor center; notably those contained in the blood in renal disease, in eclampsia, in diabetes, and in nicotine or lead poisoning.

Gout, syphilis and lead in part, at least, seem to cause hypertension, perhaps rather through the structural changes they produce in the arteries than through any constrictor influence. Typhoid fever causes hypertension, according to Dr. Thayer's[3] observations, apparently in the same way.

To openly avow ignorance of the exact nature of a condition does not necessarily preclude the value of its recognition nor of a tentative analysis of its manifestations. Though we are still ignorant of the exact etiology of primary pernicious anemia, the recognition of its claim to notice as a distinct disease has been productive of much good; and, further, gives a more correct and definite trend to any investigations concerning its etiology, than if it was still confused with other anemic conditions. Though the terms primary, idiopathic and autotoxic have undoubtedly been much abused, abuse should not necessarily prohibit moderate use and until more exact analyses shall permit greater accuracy, these terms will prove of assistance.

Whenever a symptom completely monopolizes the clinical picture and recurs over and over again in just the same way in the absence of any constant discoverable disease, it deserves individual recognition as a distinct clinical entity. In certain definite cases of hypertension no organic disease can be determined on as an etiologic factor, and where present evidently exists as a complication or a result, rather than as a cause of the condition.

Primary hypertension may be defined, then, as an affection in which a persistent increase in arterial tension gives rise to certain symptoms, preceding the development of any discoverable organic disease, unassociated with any constant pathologic lesion, and which.

---

[3] Thayer: Jour. Med. Scien., March, 1904.

finally, produces organic changes, particularly in the heart, blood vessels and kidneys.

ETIOLOGY.

Heredity apparently plays an important part in the production of this affection. Certain families show a marked tendency to the early development of cardiovascular and renal diseases, the organic changes in the majority of cases being antedated by a gradual rise in arterial tension. This tendency is particularly common among the males of such families.

Between the ages of 45 and 60, these men begin to show signs of the wear and tear of life, while many of their compatriots are still in their prime. Advanced grades of arteriosclerosis are not common. The condition is particularly associated with certain forms of gastrointestinal intoxication, this tendency being present in two distinct types; one represented by the large plethoric individual who eats inordinately; the other by the sallow poorly nourished dyspeptic, in whom the catarrhal enteritis and defective elimination induce a condition of chronic toxemia. In both instances the condition is one of autotoxic contraction of the arteries; the former, with normal quality of digestion, poisons himself by the mere excess of digestive and bacterial products above the needs of healthy nutrition; in the latter, faulty digestion and disordered assimilation give favorable opportunity for the absorption of putrefactive products instead of the normal products of digestion.

Constipation in itself is not necessarily accompanied by toxemia, and, therefore, does not necessarily induce hypertension. Purgation as a means of elimination is a most valuable adjunct to the treatment of many toxemias, but the mere fact that the bowels do not move every day by no means indicates toxemia. Indeed, in many cases of extreme constipation, where the bowels are not emptied more than once in a week or so, there is no subjective symptoms of poisoning and no hypertension. The very sluggishness of the intestinal movements indicates a paucity of the decomposition products which normally stimulate peristalsis.[4] So far from the failure to defecate in these cases being a cause of injury, it is merely an indication of unusual freedom from a possible source of intoxication. Such instances are best illustrated among the poorer classes, where all the nourishing elements in the insufficient food supply are eagerly seized on by the healthy digestive apparatus and quickly absorbed, so that nothing is left by the time the colon is reached to afford media for the production of the bacterial products which normally induce expulsion. Of course, where digestive disturbances or excess in eating encourage undue bacterial decomposition, the constipation becomes a very active factor in increasing the amount of toxins absorbed.

Some people can regularly have intervals of a week or more without a stool and keep in excellent health; others suffer headache, giddiness and nausea, and exhibit marked increase in pulse tension if a single morning evacuation is omitted. Large frequent stools, which are a necessity for the wealthy gourmand or dyspeptic, would be for the healthy active poor an unnecessary extravagance.

Mental strain undoubtedly plays an important part in the development of hypertension. Mosso has shown that emotion causes a spasmodic contraction of the arterioles. Continued care, worry and emotion induce chronic hypertension, and this influence is especially shown by the prevalence of the disease in those occupations to which they are incident. Huchard[5] says: "Strong and repeated emotions can induce cardiac affections by their incessant action on the peripheral circulation; this is one of the reasons why, according to my observations, arteriosclerosis is so frequent in members of our profession. It is the disease of medical practitioners, because their profession is associated with emotional and nervous overstrain; for the same reasons, it is a disease of politicians and financiers."

Here, again, as so often occurs in the literature of vascular disease, arteriosclerosis and hypertension are apparently used either synonymously or with a very indistinct idea of their relation to each other.

Sedentary habits prevent elimination, and so add materially to the toxic and hypertensive tendency. This is especially true of the eliminative functions of the skin and the intestines. The relation of renal function and changes in tension within physiologic limits is so obscure that it can not be opened here. The subject has been carefully studied by Dr. Erlanger of the Johns Hopkins Hospital, and his results will be published later in the *Johns Hopkins Bulletin.*

Furthermore, the complicating factors of any of the other causes of hypertension, previously stated, will, of course, augment the primary condition, and both hasten and direct its termination.

PATHOLOGY.

I have begun further studies of the pathology of this condition, which will be detailed later. The most frequent and striking findings are cardiac hypertrophy and dilatation, hyperplasia of the media in the systemic arteries, which may be markedly tortuous; thinning of the cerebral arteries; hypertrophy and engorgement of the kidney, the so-called arteriosclerotic kidney, or in later cases atrophic cirrhosis of the kidney, small granular kidney.

SYMPTOMS.

Symptoms may be divided into two stages—before and after the onset of complications—which give definite signs in one or in another organ. In those cases, especially referable to autointoxication of digestive origin, the first symptoms may be merely lassitude, constipation, headache, throbbing of the temples on exertion, and the patient may look run down, and a tonic may seem to be indicated. These patients are usually young adult males, perhaps of neurotic tendency, and often excessive users of tobacco. No signs of organic disease can be made out. The pressure will average from 40 to 60 mm. Hg above normal. Frequently the first symptoms are complained of between 40 and 50 years of age. There may be slight mental changes and noticeable irritability of temper, and a tendency to become low-spirited and morose. The sleep is uneasy, and may be occasionally interrupted shortly after retiring, in a struggle for breath or with merely a distressed feeling around the heart. Heavy suppers and high living in general is not borne so well, and may be associated with dyspeptic symptoms. Exertion more readily induces shortness of breath.

. Preliminary symptoms may be absent or neglected until an attack of vertigo, acute bronchorrhea, cardiac dilatation or apoplexy demand medical treatment, or end the case suddenly. Perhaps the applicant seeks his physician in surprise at being declined by some life-insurance company because of a trace of albumin in his urine. These cases average a pressure of 160 to 200 mm. Hg (9 cm. armpiece), and most frequently are in men in active business or professional life.

PHYSICAL EXAMINATION.

The one essential finding is systolic hypertension in the systemic arteries. This varies from an increase of 20 to 100 per cent. above normal. The arteries often pulsate visibly, tend to become more and more tortuous with the duration of the condition, and slow thickening. Evidence of sclerosis or of degenerated changes in the wall with hardening and ring formation is not present except inconstantly and in the later stages. Definite distinction must be made between the hypertrophied tortuous artery, so characteristic of chronic hypertension, and the hard, ringed quill or pipe-stem artery, often nearly straight, of arteriosclerosis, where an increase in tension is by no means essential. The frequent error of taking the two conditions to be evidences of the same process is to be deprecated.

After the blood current has been shut off by proximal compression, the artery of hypertension is found to be distinctly thickened, and makes a more palpable cord to roll between the finger and the bone, but the walls collapse easily, show no irregularities, and give the impression of softness in spite of the thickening. The sclerotic artery resists pressure, is irregular or ringed, and feels distinctly hard.

Professor Sansom considers when the pulse tracing shows an ample dicrotic wave, indicating on the part of the vessel lack of ability to accommodate caliber to its contents, that degenerative changes are present, rather than true muscular hypertrophy. My observations with the sphygmogram tend to confirm this deduction. Further, Dr. Oliver considers the loss of normal variation in caliber in response to changes in physiologic condition an important aid in distinguishing sclerosis. A decided loss of ability on the part of the artery to respond to vasodilator drugs is another condition which I have found associated with sclerosis.

Cardiac hypertrophy, which is always present as a physiologic response to increased peripheral resistance, in the earlier stages, and in fleshy individuals, particularly in women with pendulous breasts, may be difficult to determine definitely. Chronic hypertension is a surer indication of hypertrophy than the outline of percussion dullness.

The urine is variable. In the earlier stages with marked intoxication the urine may be of high specific gravity, and form a heavy sediment of urates. Later, with the more pronounced cardiac hypertrophy and higher tension, the blood supply to the kidney becomes excessive and the urine becomes of lower specific gravity, and may at times of extra strain show a trace of albumin. A systemic pressure in the neighborhood of 200 mm. Hg, obtained with a 9 cm. band, seems to indicate approximately the limit of renal resistance to albuminous exudation. The kidney is now enlarged and reddened, the so-called arteriosclerotic kidney, evidently not a true primary sclerosis. Later, sclerosis may develop, as in all chronic congestions, and the kidney may pass on to the stage of cirrhosis or small granular kidney.

Such a condition could not properly be called Bright's disease or nephritis. To quote from Mahommed,[6] the term is too general for scientific use, for, as applied by some, it has become synonymous with albuminuria. My observations tend to confirm his views that intermittent or chronic albuminuria does not necessarily mean nephritis, though his tendency to describe all urinary changes, usually attributed to nephritis as the result of hypertension, is extreme. But the element of truth in his deduction should not lose its value on account of the radical extent to which it is applied.

His crude methods of measuring tension with the sphygmogram led him to this significant conclusion which, on account of the coincidence with the results of my own work, I take the liberty of quoting at some length: "First, previous to the commencement of any kidney change or appearance of albumin in the urine, the first condition observable is high tension in the arterial systems, due to the presence of noxious material in the blood. If this condition be allowed to continue, albumin is subsequently found, and if still unchecked or uncontrollable, Bright's disease in one of its forms appears.

"I believe that the chronic condition of increased blood supply produces increased growth of the interlobular connective tissue, and if still continued, this must result in contraction, and induration, atrophy of the tubules from constant pressure, would now ensue. This sequence of kidney changes agrees with that described by most observers. In confirmation of this view of the commencement of these changes, I have frequently observed a condition of high tension in the pulse in cases that have subsequently developed albuminuria and symptoms of cirrhosis of the kidney."

He asks, "Can the term 'inflammatory' be fairly applied to this disease?"

Anemia is not a prominent symptom. The cases, in fact, frequently are examples [illegible] fascies. Where there is pallor the anemia is apparent rather than real, caused by the peripheral constriction. Edema is a symptom of the complications, not of hypertension.

COMPLICATIONS.

Complications are determined by the organ that is least enduring of the strain. Cardiac dilatation and myocarditis, albuminuria, arteriosclerosis, apoplexy and bronchorrhea occur about as in order named. The compensatory cardiac hypertrophy can correct the evil for a certain length of time, but sooner or later must fail to endure the ever-increasing load.

Dana says: "It has been shown in many cases before the onset of cerebral hemorrhages, there has been for some time a gradual rise in general blood pressure which has thrown an undue weight on the work of cerebral blood vessels." Finally the limit is reached, and a vessel ruptures.

In the two decades in which hypertension usually reaches its maximum—from 45 to 65—43 per cent. of all deaths from apoplexy occur.

DIAGNOSIS.

A diagnosis of chronic primary hypertension is dependent on the demonstration of a chronic increased arterial pressure and the exclusion of organic disease, or evident toxemia, which could account for it. As accurate estimations of pulse tension come into more general use, the condition will more frequently be recognized during the early stages, and before some organic manifestation attracts notice to the hypertension which will then, in most cases, probably be regarded as a symptom rather than the underlying causative factor. After several organs show marked changes the sequence of events becomes obscure.

---

[6] Mahomed: Med. Chir. Trans., 1874, p. 197.

I have lately seen a case of vertigo in a financier of 60 treated by active stimulating drugs, and who died the same night of apoplexy. A course of nitrite based on an estimation of hypertension would almost surely have averted the attack. Also, I have seen a case of repeated attacks of acute pulmonary edema with intermittent albuminuria, variously diagnosed bronchitis, congestive chill, arteriosclerosis, etc., in which the pressure averaged 200 mm. Hg, and where eliminative and depressant treatment has so far prevented a further attack; also another case of so-called "weak heart," in which there was a blood pressure of 190 mm. Hg, with headache, nocturnal dyspnea, and suffocating feeling of impending death around the heart. No albuminuria nor casts nor arteriosclerosis. By reducing the tension to 160 mm., the symptoms were relieved. Except in an infectious disease, no judgment should be formed of a patient over 40 without a knowledge of the blood pressure, and the routine estimation of this symptom in every case will permit a more frequent recognition of the first stages of the primary form of hypertension.

TREATMENT.

Treatment may be divided into two parts:

First.—Early treatment where a correction of the tension usually may be accomplished by dietary and hygienic measures.

Second.—Late treatment where the administration of specific drugs supplementing the general treatment is necessary in order to overcome the condition.

The first division needs no comment here, except notice of the fact that a meat diet seems to have a very strong and direct influence on initiating and continuing a rise in arterial tension.

For the more persistent cases, where the cause can not be eradicated or where organic changes prevent restitution, we must have recourse to drugs and, fortunately, we have almost a specific for this condition.

To quinin for malaria, mercury for syphilis, iron for anemia, and adrenalin for vasomotor paralysis, we must add the nitrites for hypertension.

Drug treatment, however, should not be resorted to, except when more natural means fail, or where immediate relief is necessary (here prompt venesection is invaluable), and should be discontinued as soon as possible. In certain acute affections associated with hypertension, such as some forms of vertigo, angina pectoris, acute cardiac dilatation, tic douloureux and asthma, amyl nitrite may be inhaled quickly, preparatory to more permanent relief. The action of this drug is very transitory and ceases almost immediately with the termination of inhalation. Furthermore, the amount can be very indefinitely regulated, and the effect is proportionately uncertain. In some cases of hypertension I could discover little or no lowering of the blood pressure. In others I have observed a drop of 30 to 40 mm. Hg lasting about one to three minutes.

Nitroglycerin is likewise rather uncertain in its action and, though more constant and persistent than amyl nitrite, does not seem to deserve the prominent place it occupies in the therapeutics of various forms of hypertension. I have obtained a drop in blood pressure of 100 mm. Hg in less than ten minutes following 1/50 gr. of nitroglycerin, but there was a return to the former level of 200 mm. Hg in about an hour. In another case, after the same dose, the rhythm and tension became very irregular, and, while the rate rose to 110 from 60, there was no definite nor constant lowering of tension. There was some twitching of fingers noticed during the effect of the drug. This case and several similar ones incline me to believe that nitroglycerin must be subject to some chemical changes which may alter and impair its properties. In some cases the transitory depression only lasted 15 or 20 minutes after a hypodermic of gr. 1/100 to 1/50 nitroglycerin, and never much over an hour. The pulse is usually increased in frequency and sometimes alarmingly so. In several cases taking a 1/100 gr. triturate every three or four hours week in and week out I could find no definite effect from a single dose, nor from the aggregate doses. There seemed no instance in which the patient would not have been benefited by substituting sodium nitrite for nitroglycerin.

Sodium nitrite may lower the blood pressure for from two to three hours, occasionally as long as four. This is unaccompanied by more than a very slight increase in pulse rate. There may be a feeling of flushing and throbbing, as with other vasodilators. The reaction from 1 or 2 grains averages a fall of from 25 to 50 mm. Hg coming on rapidly in from 5 to 10 minutes on an empty stomach, and more slowly when taken after eating. Where a uniform permanent effect is desired, after meals seems the best time for administration, as the effect is not so abrupt and is more lasting.

I have obtained a fall in blood pressure from aconite, but my observations with this drug are so limited that I can not confirm Dr. Thompson's favorable report of its use as a vasodilator in nephritis.

CONCLUSIONS.

Chronic hypertension may be divided into 4 classes, according to etiology: (a) arteriosclerotic; (b) cardiac, pulmonary and cerebral compensatory; (c) toxic; (d) primary.

The primary form of hypertension deserves recognition as a distinct disease.

Early recognition of the tendency toward a progressive increase in pulse tension should prevent or delay the development of certain forms of cardiovascular and renal disease.

In correcting hypertension sodium nitrite has many advantages over nitroglycerin.

DISCUSSION.

DR. NOBLE P. BARNES, Washington, D. C., stated that vascular dilatation may be influenced by mental, physical or mechanical means. Systematic physical exercise is possibly the best method of accomplishing vascular dilatation, especially in mental and desk workers, with atonic hearts and contracted peripheral vessels. Here an hour of gymnasium work, followed by the gradually cooling shower bath every second day, will accomplish great good. Mechanical dilatation of the peripheral vessels suggests itself in the incipiency of pneumonia, convulsions of infants and conditions of shock. Counter-irritants, as the hot mustard bath or foot bath, are of recognized value in equalizing the circulation. Arteriosclerosis puts in its appearance about the time the thyroid gland begins to atrophy. As this gland has vasodilating properties, the administration of the extract might be useful in these cases. Amyl nitrite is a prompt, efficient and convenient drug, indicated in angina pectoris, epilepsy and similar emergencies. Nitroglycerin acts less promptly, but has more lasting effect; while sodium nitrite and erythrol nitrate are best for continued use, their action being less powerful and more permanent. Drugs acting centrally to produce vasodilatation most likely do so by depressing the vasoconstrictor centers.

Dr. C. E. De M. Sajous, Philadelphia, referred to the influence of the pituitary body on arterial hypertension. He said that Professor Cyon of Geneva, and more recently Masay, by stimulating this organ produced all the manifestations of increase of arterial pressure; in other words, they obtained an enormous rise of arterial pressure. The merest touch sufficed to raise the pressure, while the current brought it to a very high level. In the course of another experiment performed while studying the causes of cerebral pressure, Cyon observed that all the reflex phenomena obtained by stimulating the nasal mucous membrane, such as sneezing, coughing and increase in secretion, could not be obtained when the pituitary body had been removed.

Dr. William F. Waugh, Chicago, objected to the use of the nitrites as vasodilators for chronic cases. He said that the nitrites are well suited to meet a temporary condition and produce a sudden rise, but from none of them can be obtained a continuous effect, not even from sodium nitrite. Their effect will pass off in a half-hour at most. For conditions in which a continued effect is required veratrin is useful. Its effects may be kept up for months. Another advantage of this drug is that it presents no possibility of accumulation, as it opens all the channels of elimination.

Dr. H. C. Wood, Jr., Philadelphia, said that it has been experimentally shown that a greater amount of blood goes to the arms and legs when the mind is concentrated on them. He took exception to the statement of Dr. Cook that there is such a thing as "idiopathic" high tension, the cases called idiopathic being simply those whose cause we fail to determine. When the nitrites are employed in arterial hypertension it is for their temporary effect; their greatest use is where there is immediate danger from the vascular constriction, as in threatened apoplexy. He agreed with Dr. Cook that sodium nitrate is the best. Tetra-nitrate and potassium nitrate have been stated to be more permanent than the nitrites in their effects. Sodium iodid and potassium iodid may act, by bringing about a change in the arterial nutrition and may be valuable in prolonged administration. Diet is one of the best therapeutic measures and has an important place among other methods of treating arterial hypertension.

Dr. Wm. C. Robinson, New York, emphasized the value of veratrum viride as a permanent vasodilator and said that by this means the blood vessels can be kept dilated for weeks at a time. It has been used in nephritis and other conditions of high tension with good results. Dr. Lauder Brunton especially recommends the crude potassium nitrate, which has been found to contain a small proportion of potassium nitrite. Perhaps the good effects are due to this fact.

Dr. Joseph Clements, Nutley, N. J., stated that he has a valvular lesion of the heart, and after walking several blocks he is liable to feel distress and pain in the pericardium and in the region of the liver. He always has with him some tablets of glonoin. One of these tablets will, in two minutes, begin to ease the distress. The hypertension is quickly relieved, and he is able to go on walking, or with whatever he may have been doing, which caused the tension of the blood vessels and the distress and pain. Even standing for any length of time to speak will sometimes induce this condition, which is usually relieved on taking a tablet or two.

W. W. Tompkins, Charleston, W. Va., recently had a patient who took a pearl of amyl nitrite and crushed it in his handkerchief and inhaled it. He immediately fell as if struck on his head and had such intense vertigo that he had to go to bed and remain there for ten days. Every time he lifted his head he had vertigo and if he tried to stand he fell to the floor. This may be a case of idiosyncrasy, as Dr. Tompkins never heard of another case in which amyl nitrite acted in this way. The man did not use the drug because he needed it, but it was ordered for another member of the family and he took it on his own account to see what effect it would have.

Dr. O. T. Osborne, New Haven, Conn., agreed with Dr. Cook that the nitrites do good in these cases of hypertension by their prompt action in dilating the blood vessels and reducing tension. The iodids belong to the alterative treatment. The thyroid gland gives out a vasodilator substance and the adrenal glands give out a vasoconstrictor substance; these exercise an important influence on the circulation. The thyroid gives out an iodin substance, and we can understand how the iodin may do good when administered to these cases by stimulating the thyroid to extra secretion, especially at the age when this gland begins to atrophy. Dr. Sajous asked if the iodin stimulates the thyroid gland.

Dr. Osborne, in reply, said that all the iodids stimulate the thyroid of extra secretion, as can be demonstrated in Graves' disease.

Dr. H. W. Cook stated that, owing to want of time, he was obliged to omit the hygienic part of the treatment in reading his paper, and perhaps this has given rise to a false impression of the effects of treatment. In his experimental work he has obtained a result of a fall of 120 milligrams, lasting for two hours, from a dose of sodium nitrite. He thinks that in these cases of chronic arterial hypertension, what is needed is decreased arterial resistance rather than decreased work of the heart.

THE THERAPEUTIC VALUE OF MASSAGE IN ACUTE DISEASES.*

JAY W. SEAVER, M.D.
NEW HAVEN, CONN.

The question of nutrition underlies the activity of every organ and tissue of the body. In general, we may say that nutrition is dependent on circulation, and that this is a double process, or rather a single nutrient current that becomes divided into two in the capillary regions. At the point of division it is not only distributed by two entirely distinct sets of tubes, but the rate of flow is widely different, as is the quality of the contained nutrient stream. The blood is ordinarily looked on as the great nutrient tissue of the body. It has its well-defined cells which carry on individual functions of widely different character, according to the nature of the corpuscle, but the intervening plasma, or stroma substance, lying between these cells, is the carrier of most of the nutrition that the various structures of the body need, as it is also the remover of their waste products.

The speed of the blood flow is such that material gathered from it must be withdrawn by chemical activity rather than by the physical processes of diffusion and osmosis; but as the removal of waste requires rapidity of flow, it becomes desirable that the purveyor function should be to some extent separate from the eliminative function. For this purpose the blood vessels, at the areas where the blood flow is slowest, are so constructed that they permit the blood plasma to flow through into the intercellular spaces of the various organs, and these intercellular spaces are more or less filled with this leakage material that thus bathes the cells with a nutrient fluid which moves comparatively slowly and which permits free interchange with the protoplasm of the cell. In this way nutrition is maintained.

Near the periphery of the organ or any of its segments, the intercellular spaces take the form of well-defined ducts, and these are called lymph vessels, being supplied with valves at frequent intervals that permit the movement of their contained fluid in only one direction, which is toward the periphery of the organ. When we pass beyond the limits of any individual structure, we find that the lymph ducts in general are continued toward the center of the body, while along the course of the lymph vessels, or lymphatics as they are called, are found frequent glands into which the vessels pour their contents and from which fewer lymphatics lead on to the center of the body. In some regions, as in the neck, these glands are extremely frequent, so that the lymph is strained before it has passed any great distance from its point of origin. In other regions, like the arm and leg, considerable distance may be traversed before the lymph is poured into a gland, and it is interesting and important to note here that in general these lymph glands are located in the region of joints, and usually on the flexor sides of the joints, so that any movement of the limbs, neck, etc., tends to temporarily compress the glands and also to press on the lymphatics so as to drive the lymph along toward the center of the body. This may be called a natural massage of the lymphatic area, and its importance will be noticed when we compare the edematous condition of a limb that is kept perfectly free from movement with the fine circulation of a limb that is adequately exercised through the whole range of its possible motion.

---

* Read in the Section on Pharmacology of the American Medical Association, at the Fifty-fifth Annual Session, June, 1904.

This brings us to speak of the causes of the lymph flow, which are, in brief, the residual or leakage pressure which is carried through from the blood, and, more important under ordinary conditions of life, mechanical pressure. Under this latter head we must classify not only the pressure created by change in form of a part by muscular contraction, but muscular pressures produced in various regions by different physical acts, as in walking, sitting, carrying burdens, etc., and also the minus pressure produced in the thorax during inspiration.

In conditions of extreme inactivity, as when we are sleeping, the lymph flow is extremely slow, because every element of propulsion is reduced in quality, the aspirations of the thorax being more constant than any of the other forces. During violent physical exercise the lymphatic flow is greatly accelerated, because every element of propulsion is pushed toward its maximum, both the heart and respiratory organs responding in direct proportion to the amount of muscular work done.

The difference in lymphatic pressure and speed of flow has been beautifully illustrated by a case that has come under my notice that is worth recording.

Patient.—A young man, aged 20, came to me with a peculiar discharge from the upper part of the thigh over an area of about 7 cm. in diameter, lying immediately below Poupart's ligament on the left side.

History.—At about 8 years of age, he had suffered from a bubonocele, the cause of which was not absolutely certain, although he thinks it was due to a blow in that region. The inflammation at this time must have been excessive, and while medical care was given the patient surgical interference was not used until the cyst burst and evacuation took place by natural methods. The disintegration of tissue must have been extensive, as indicated by the size of the cicatricial relic of the inflammation. The abscess had not invaded the abdominal integument, and the line of Poupart's ligament removed a segment of what would otherwise have been a fairly circular scar.

Examination.—This young man was apparently in perfect general physical health, and had been playing football the afternoon before I saw him in the evening. He had a towel around his thigh, which was wet, and I found it was saturated with lymph that was exuding from the cicatricial area *in perhaps* a dozen places, and there were about as many more spots that looked like small blisters, from the size of the head of an ordinary pin up to a bulla 3 mm. in diameter. He told me that all these openings that were oozing first appeared as blisters, and that if I were to open one of those blisters it would leak a fluid such as the others were discharging. I found this to be the case, and that the discharge of one of these openings would amount to a drop in about from thirty to forty seconds, some of them oozing more rapidly than others. Any one could be easily isolated by lightly pressing a tube over it, and the discharge be thus collected. On microscopic and chemical examination, this fluid was found to be pure lymph, and the case afforded an unusual opportunity to observe the influence of active and passive exercise on lymph flow. This case had repeatedly gone through this leakage process, and the patient was in no way alarmed at his condition. He knew that if he remained quiet for a period of two or three days the scar would heal over and would remain intact until he indulged in fairly vigorous exercise again. He was of active temperament, and for a period of three years I had an opportunity to observe him under normal conditions, with the lymphatic flow just beginning, as well as at its height, and while subsiding.

A study of this case under the influence of various positions and forms of activity showed that a high elevation of the leg soon caused a marked diminution in the amount of flow, and this was the quickest method of relief that would permit the healing over of the opening of the cicatricial tissue. It was also demonstrated that a massage of the muscles of the leg produced an increased flow of lymph that was continued for some little time, and that appeared to be due to two causes: First, an immediate exit of lymph due to pressure on the lymphatic vessels and lymph spaces; and, second, a prolonged secondary flow apparently due to hyperemia of the structures that were massaged. The importance of this case in demonstrating the value of appropriate massage in stimulating the flow of lymph and blood is greater than the indirect evidence produced in the diminution in the size of parts and the reduction of edematous conditions, for the time relations existing between the movements and the flow could be readily recorded.

ACTION OF MASSAGE ON THE NERVOUS SYSTEM.

A second value of massage that I wish to mention is with reference to its action on the nervous system. Here we have a complex matter that is not completely understood, but that has certain salient points so definite in character that we may properly discuss them as scientific truths.

The first feature of nerve activity that is started by massage is a sensory impression that accomplishes several things. First, the attention of the patient is diverted from the seat of pain or of discomfort, with such psychic results as directly relieve the discomfort to a greater or less degree, according to the mental poise of the patient and the ability of the masseur to establish satisfactory sensory impressions. This relief of mental attention is highly favorable to reparative action. It was demonstrated several years ago that the centering of the attention on any given part of the body, like the hand, was capable of elevating its temperature to a very considerable extent, and it has been repeatedly demonstrated that the unfavorable mental anxiety regarding the pain of a part results in increased hyperemia of the part, with corresponding increase in pain from the stretching of sensory nerve fibers throughout the area involved. The converse of this proposition must be true, that if the blood be diverted to remote parts through nervous intervention the congested area will be appreciably relieved.

Second. The vasomotor nerves react to surface impressions, as well as to muscular movements, and the blood may be diverted to remote areas by such movements as will cause a reflex dilatation of the blood vessels in these parts. It should be noted in this connection that a vasodilator action over considerable areas will tend to diminish the total blood pressure, and for this reason massage has been used with such great success in cases of valvular lesions of the heart.

Third. The deep reflexes that control normal balance between parts are kept in action so that an approximation to general health is maintained while the body is undergoing local disease—for in a sense nearly all acute diseases are local—and the healthful functioning of one part assists in the normal activity of all.

When we consider how greatly the blood supply to any given part is dependent on nerve control of the vessels leading to that part, we shall appreciate at once how an appropriate appeal to nerve centers may so far modify circulation as to give relief from pain and promote healthful repair. By appropriate massage the blood supply may be distributed fairly evenly throughout the body, and all organs remain in a fair condition for functional activity, even when acute disease is strongly tending to dam it up in some definite locality.

MASSAGE IN PROLONGED ACUTE DISEASES.

Another important result of massage in prolonged acute disease is the improved nutrition that the system has through the crowding into the nutrient circuit of the material that is naturally provided by the retrograde metamorphosis of cells throughout the body. We are taught in our elementary physiology that in periods of starvation a sheep becomes an example of carnivorous feeding because its own cells give up the material that afford nourishment to such parts as must maintain a fairly regular degree of activity, such as the heart, respiratory muscles, etc.

When the muscles are called into action by volitional movements they consume in a catabolic way the material that might be given off by diffusion and osmosis to the lymph and blood vessels, and so be carried around to nourish the tissues whose activity must be fairly regular and constant. In this way life may be prolonged when the natural nutrient canal is unable to retain or absorb and appropriate the proper nutriment for the body. This phase of massage is more important than has usually been conceded, for it gives a possibility of rest to organs that are unable to functionate and carries the system along until the natural methods are restored. This process renders available much of the fatty tissue that is stored in the skin and in the abdominal cavity, and which, if left inactive and with poor blood circulation, could never be recalled as fuel, although its primary function is that of stored food.

With the above view of the physiologic grounds for advocating massage, the question will naturally arise as to what may be the value of the art in acute diseases. Already it has won a place for itself in the treatment of chronic cases where appropriate stimulation is needed if repair is to be encouraged and facilitated. There is a certain line of cases, like the zymotic diseases, where the benefits of massage may seem more or less problematical, and as this is a field which has not been occupied by any except the more expert and careful masseurs, we must appeal to our physiology in support of this means as a rational help in the treatment of these cases, especially at certain stages of the disease. In such a condition as pneumonia or typhoid fever, where the heart action becomes a matter of solicitude, there would be absolutely no contraindication to the use of massage, if properly applied, to diminish the burden carried by the heart and thus improve the patient's condition and ability to endure the other hardships of the disease.

In typhoid fever the failure in heat elimination can be partially remedied by appropriate manipulation, but I believe that the most favorable results will be produced on the circulation and nutrition. As it is a disease that locally affects the nutrient canal and renders it unfit for its work of digestion and absorption by reason of the high temperature and inflammation of the mucous membrane and intestinal glands, it is desirable, therefore, not to require more work of this particular organ than is absolutely necessary. So we may resort to the utilization of stored food that can be brought into the circulation from storage cells as well as from the muscles themselves. This will maintain the vitality of the patient through prolonged periods without the possibility of fermentation and decomposition changes going on inside of the intestine where their products will prove specially irritating to surfaces that are already tending to break down or that have broken down and present ulcers of rodent type. We know through experience with wounds on the external surface of the body how quickly their character changes when decomposition products are brought in contact with them, and we must believe that the same changes occur in parts that are not readily open to inspection. We have proved that these products produce increased inflammation, as shown by the elevation of temperature, tympanites and the poisoning of the central nervous system that formerly so frequently resulted in active delirium, but more recently rarely reaches this condition of toxemia.

EFFECT OF EXERCISE ON THE BLOOD.

An examination into the modifications of the blood that are caused by exercise has been made by Drs. Mitchell and Babbitt of Philadelphia, and Dr. McCurdy of Springfield. Their investigations seem to show that the corpuscular element of the blood is increased by both active and passive exercise, and while this is probably due to what may be considered a more even distribution of the corpuscles throughout the vascular system, it would appear that in any form of acute diseases such an even distribution is greatly to be desired from a physiologic standpoint. In the zymotic diseases the increase of leucocytes is highly desirable, and any process that does not produce injurious effects in other respects and that will cause an increased leucocytosis, would naturally be employed.

MASSAGE IN PARALYSIS.

My principal plea for the employment of massage is for the effect which it has on the nerve centers and as an assistant to the heart by relieving it of a considerable part of its work. Where disease is long continued another condition should not be overlooked, namely, where muscular tissue is likely to undergo atrophy and cause deformity and subsequent inefficiency of the part. Such cases are constantly recurring in the practice of every physician.

I remember vividly the first case of Bell's paralysis of the facial nerve that ever came under my professional care. The patient was a young man who was studying for the ministry, and the facial condition was such as to cause great alarm and doubt as to the possible ability of the patient to carry out his plans for his life work. The paralysis was more than ordinarily severe, and yet by proper massage the tissues were not wasted nor seriously atrophied, and this man now holds a very important charge as pastor of a church in New England.

Another case that I saw afterward had not been treated for five months, and while the patient was a young man with everything favorable to repair he was unable to close his eyes or move the superficial muscles of the face, while the inability to eat with comfort and properly masticate food had led to a general condition of asthenia that was pitiable. This patient was put under massage treatment, but the tissues never recovered their normal action and form.

We have all seen many cases of muscular atrophy resulting from scarlatina, diphtheria and similar diseases. I am confident that with proper care such cases need not be left as a burden to themselves and society, but with proper intervention to prevent wasting and to improve the nutrition and innervation the great majority of cases would make a good recovery.

MASSAGE IN ACUTE INFLAMMATIONS.

In acute inflammations along the spinal tract much may be done to relieve the severity of the congestion by massage, and the assistance that may be given to Nature in establishing neuromuscular activity after a more or less severe disintegration of nerve tracts and centers is undoubtedly very great. In such acute diseases as rheumatism, the pain and congestion are greatly relieved by appropriate massage, and undoubtedly the elimination of waste matters can be greatly facilitated, for it has been demonstrated that not only will the circulation through a given part be greatly assisted, but the functional activity of the glands may be decidedly increased, as has been done in the massage of the kidneys. The sweat glands may be powerfully stimulated, and it is not uncommon to find the skin start a profuse perspiration after a few minutes of appropriate manipulation.

An important value of massage in the care of acute diseases lies in the great relief that the patient experiences from the discomfort that is due to the confinement of the disease. This is especially true of young and middle-aged people who are accustomed to a more or less active life. When disease suddenly stops muscular activity there is a tendency to nervous restlessness and actual pain due to the poor circulation through the muscles and their inability to perform their normal functions. The distaste for confinement in such cases often impels them to keep about when the physician advises a recumbent position and quiescence. By appropriate deep massage all this muscular discomfort is relieved, the circulation through the parts is established, and every condition for repair is improved, until it would almost seem that no element in the nursing of such a patient could be of greater importance than such manipulation.

At present the indication is met in the large majority of cases by superficial skin friction and the application of alcohol; and while this relieves the edema of the skin and subcutaneous areolar tissue, it only superficially accomplishes what is desired, and is to that extent inefficient.

MASSAGE IN HYPEREMIA OF MEMBRANES.

The same thing can be accomplished in diseases that is accomplished in traumatic injuries, although the ocular evidence may not be so well marked. It has always been my practice in treating fractures, dislocations, etc., to relieve edema by appropriate stimulation of the lymph vessels by massage, and I have never yet seen a case that was not greatly relieved from pain, and where the developing turgescence was not checked by this measure. It is fair and rational to assume that the inflammation excited by pain in any part of the body can be checked to a considerable extent by similar processes. If the appropriate massage of the knee joint can effectually promote the absorption of exudate, may it not equally be expected that appropriate manipulation will promote the absorption of an intrapleural effusion? Or, if the effusion is due to a prolonged hyperemia of the pleural membrane, is it not barely possible that appropriate attention given to the circulation of the blood and lymph in the thoracic wall may prevent effusion?

If any person doubts the derivative influence of massage on membranes that are untouched by the process, I ask any such person to experiment on himself the next time he has a severe coryza by vigorous massage of the skin around the base and over the bridge of the nose. The balance between what may be considered normal circulation in a part and hyperemia is so delicate that very slight nerve stimulation, if properly applied, may turn the system in one direction or the other.

MASSAGE IN NEURALGIAS.

In neuralgias the relief by appropriate manipulation is often very marked, and apparently the nutrition of the affected nerve trunk is so influenced that the normal balance is soon secured, and it is found that the pressure along the nerve trunks, to a certain extent, corresponds to a stretching that was long ago found to be an efficient method of treating persistent neuralgias. In sciatica the new method of nerve stretching has been found to be quite as efficient as the surgical method that has been to some extent in vogue. I may say in passing that this new method of stretching consists in flexing the thigh on the trunk as far as convenient, then extending the leg on the thigh so far as can be borne by the patient, and at the same time flexing the foot on the leg as a final part of the movement. This makes the course of the sciatic nerve as long as it can be made in any movement of the body, and where the nerve is extremely sensitive must be done under an anesthetic if carried to its complete extent, which is not always necessary or desirable. I think I am correct in saying that this method is essentially the only one used in the treatment of sciaticas among Scandinavian peoples, and is followed to a considerable extent in France and Germany.

Of course, the diseases mentioned are only illustrations of the general application of this great therapeutic means which has been so long neglected by our profession in this country.

TRAINING NECESSARY FOR THE APPLICATION OF MASSAGE.

It goes without saying that in acute diseases the manipulation should be applied by a person who understands the systemic needs that are to be met. This brings us to a consideration of the training necessary for the application of this method of treatment.

There is a too general feeling among the medical practitioners of the country that massage is allied with the so-called "magnetic" treatment that is practiced by some of the most arrant humbugs to be found in the country; people who profess to be able to "fill the patient with vitality" from their own superabundant stock, and who feign to be greatly exhausted after half an hour's simple manipulation that would require comparatively little expenditure of energy; or they look on the work as being simply skin friction that has no other function than the soothing of nervous excitement, the control of the attention and the setting up of certain nerve reflexes that are allied to the normal nerve activities excited by contacts in normal exercises. Nothing is to be more regretted than this superficial view of the matter. It leads to every trained nurse being expected to be competent to massage a patient, and every athletic trainer and "rubber" being considered a suitable person to act as masseur in cases that are deemed suitable for this therapeutic method. I have noted illustrations of this, to which I wish to call your attention, as they are not unique but customary.

A surgeon of some prominence, in a city of over 100,000 inhabitants, had been advised to try massage in a case of rheumatism, and he sent for a young man of Hibernian extraction, who had carried water and various athletic paraphernalia for college teams, and had finally become a "rubber" for the football team, to take charge of this case, which he did, with results that were satisfactory to the patient and the physician, except that the next time the patient had an attack of rheumatism that happened to be of fairly acute form, he called in the rubber—I can not call him a masseur—and was treated for several weeks before it was deemed necessary to call in a physician to outline other therapeutic means that were of more immediate consequence than the superficial skin friction, accompanied by more or less oily liniment that had been used.

A second case illustrates the need of training for masseurs. A person suffering from constipation and muscular atony was advised to have massage, and a trained nurse was called in to attend to this phase of the treatment, as she was reputed to have considerable skill and a "magnetic" touch. She manipulated the case in a superficial way with considerable nervous satisfaction to the patient, who insisted that she was improving under the treatment; but her constipation received no benefit whatever, and the manipulation was not sufficiently deep to promote the circulation in the muscular tissues, and she finally became so weak and anemic that she gave up the treatment in despair, and was ordered South for a change of climate. There she fortunately fell into the hands of a physician at a sanitarium, where massage was prescribed, with passive exercise and resistive movements, by a physician who knew what ought to be done and had an attendant who was capable of doing it. The gain was immediate, and the lady returned to her home after two months in greatly improved condition, and her health has remained satisfactory.

I am frequently in communication with sanitariums and hospitals that are inquiring for masseurs to take up the work in their institutions, and I never yet have found but one such place where a masseur was treated as anything better than an ordinary ward master, and they are usually paid about the same wages.

In Sweden, which is the home of medical gymnastics, the government supports a school where three departments of physical training are taught. A course of military gymnastics for the training of the officers for their army and navy; a course in educational gymnastics to train teachers for public-school work; and a course in medical gymnastics for the training of experts in kinesitherapy. In addition to the educational and physical requirements for entrance to the school, there is a course of two years during which the pupil is trained in anatomy, including dissection, physiology, kinesiology, pathology, and practical work in both active and passive exercises in all forms that have been found advantageous from a therapeutic standpoint. During two years these pupils have the advantage of daily work in a clinic, where the new men are taught under the supervision of the senior class and the director, who is a trained physician. In the city of Stockholm there are at least five great clinics where patients are treated by this method, either at public or private expense. The work done in these clinics is co-ordinate with the work of the medical clinic. Cases that happen to go to a medical college are referred to the gymnastic clinic if this therapeutic method seems indicated; and, on the other hand, if a case reported to the gymnastic clinic that was obviously a case for medical treatment, it would be referred to the appropriate place. I happened to be in the Royal Central Gymnastic Institute when a sailor appeared for treatment, who evidently had what is so common in this country, but so rare in Sweden that it was not recognized, namely, a case of tertian malaria, with the characteristic chills and rise of temperature. This case was immediately referred to the medical clinic on my diagnosis; and, on the other hand, cases were daily appearing with cards from the medical clinic to the gymnastic clinic. From observation of work in this line in Stockholm I estimated that from 400 to 500 cases a day were thus treated in more or less public institutions.

Where the medical profession has been trained to an appreciation of scientific exercise, and where the masseur has a training in the proper application of exercise, the two work hand in hand with a most gratifying success. For the physician may direct a certain form of exercise that is indicated for the patient, and be sure that in dosage the masseur will be competent to execute his orders with exactness and a trained appreciation of what is to be done. The assistance given to the practitioner is akin to the assistance a trained surgical nurse gives in preparing for an operation and in the subsequent dressing of the wound—an assistance that makes modern surgery as efficient as it is.

May I suggest that in this country our needs lie in two directions?

First, instruction in the medical schools, that is now almost entirely omitted, that should put the students in possession of the theoretical basis of active and passive exercises, from a physiologic and from a therapeutic standpoint. Also, such practical instruction as would make the physician a competent judge of the quality of the work that should be expected of a masseur. A department for this form of instruction is certainly not unreasonable, for in the better class of medical schools courses in pharmacy are given in order to acquaint the student more thoroughly with the appearance and physical qualities of drugs in the various combinations in which they are ordinarily prescribed.

The second need is in the line of more thorough training of people who wish to practice kinesitherapy. May I suggest that the work done in training for this line of activity should cover at least two, and better three years, the theoretical instruction being parallel with the instruction of the first two years in the best medical schools, except that the emphasis should be laid on physiology and anatomy, with the time now devoted to chemistry turned toward theoretical and practical demonstrations and practice of the technic of medical gymnastics. I believe they should have some training in materia medica in order that they may understand the physiologic effects of the commonly used drugs; they should also be made familiar with hydrotherapy and other forms of mechanical treatment. The person who completes such a course should be given a degree or professional title, like "Medical Gymnast," and be legally registered for practice, in order that the people at large may know that the practitioner has received a stated form of training for his work and passed definite examinations to establish his ability to practice. This would give the medical practitioner a trained assistant, whose ability might not always be of the highest grade, because even the title of "M.D." conferred by our largest institutions does not always guarantee a competent practitioner; yet on the whole it will raise the standard of work and give an assurance to the people that the person employed is qualified for the work for which he is paid; and the incompetent will be weeded out by the laws of the survival of the fittest as they enter into competition with each other. With the status of the masseur thus determined, the fakirs who now parade under other names but "wear the livery of Heaven to serve the devil in" would be forced into some other line of activity.

In many of our larger cities it is possible to find men and women of rare ability who have been thoroughly trained for the work that they do and whose relations to the medical practitioner are most loyal and satisfactory. I happen to know of such people whose character and attainments are of the very highest order, and whose professional earnestness and honor may well be a model for any of us.

I am not arguing for massage as a panacea, or as the only therapeutic means of value. I simply claim for it such a rational basis for its practice as is furnished by the most thorough knowledge of physiology, and a knowledge of the psychoneural control of many of the pathologic and physiologic processes of our bodies. By this neglect we have put in the hands of illegitimate practitioners an instrument that they have wielded to the advantage of many patients and to the much greater advantage of their own pocket books.

The chemical elements and their combinations are not the only means of awakening or subduing physiologic action. In fact their influence has undoubtedly been overestimated by the practitioners of the past; and while we may take well-deserved credit to ourselves for the beneficent results obtained through drug medication during the hundreds of years in which it has occupied the chief attention of the profession, we must also bear the onus of the extensive drug addiction that is to-day one of the great curses of the human family.

DISCUSSION.

Dr. J. W. Foss, Phoenix, Ariz., said that his experience confirms the statements made by Dr. Seaver. The suggestions made by Dr. Seaver, if adopted and carried out, would assist the practitioner to obtain greater success in the treatment of disease. By the aid of massage results are achieved which can not be obtained by other means.

Dr. R. C. Newton, Montclair, N. J., considers that Dr. Seaver's paper opens up a large subject, much of which is little understood. Rubbing a patient vigorously during a bath is an essential part of the Brandt treatment of typhoid fever. If the patient is simply put in the bath and left there, the bath might do more harm than good. Owing to its beneficent effect on the circulation, rubbing might be made a part of the treatment in many other fevers besides typhoid. In old, helpless patients much good can be done by rubbing them thoroughly as well as by giving them baths. In cases of so-called sluggish fever with vascular congestion, and in neurasthenia and weak heart, this treatment should be carried out as a matter of routine. There is perhaps no more important phase of therapeutics to-day than massage; and there is no question that the average practitioner needs much enlightenment on its uses, limitations and dangers.

Dr. Heinrich Stern, New York City, in replying to a question, stated that the physiologic effects of massage are of quite a complex nature. They are for the greater part purely mechanical, but also thermal and electro-osmotic. Its total action is exerted on the circulation and the fluids of the deeper-seated tissues, modifying the processes of metabolism. Massage enhances the permeability of various organs, at least re-establishes normal semipermeability in those tissues which have lost their natural characteristics during certain inflammatory processes. By massage the exudate of the serous and synovial membranes, the consequence of acute articular rheumatism, is removed, the membranes resume their normal functions which to the greater extent are only those depending on their normal semipermeability. Every measure tending to re-establish the normal osmotic equilibrium must be considered an osmotherapeutic.

Dr. Jay W. Seaver stated that, owing to lack of time, he had to omit some matter in reading which would have covered the points suggested by Dr. Stern. It has been shown that there is a derivative action produced by these osmotic changes which have been set up. Massage of the kidney causes an increased flow of urine from it, as proved by physiologic experiment. This and other facts show that when we as practitioners neglect valuable means of treatment we leave a fertile field open for cultivation by irregular practitioners who are not slow to occupy it.

REPORT ON THE PROGRESS IN ACTINOTHERAPY DURING THE PAST YEAR.*

WILLIAM S. GOTTHEIL, M.D.
Dermatologist to the City Hospital and to Lebanon and Beth Israel Hospitals.
NEW YORK CITY.

My report will be comparatively brief, since the past year has not been marked by any very important changes or improvements in the actinotherapeutic method. The workers in the field are still few, and for obvious reasons. The apparatus required for its effective employment is, it must be confessed, large and expensive. It is essentially one for institution use; for the cost of installation, the room required, the length of time of treatment, and the restricted classes of patients for which it is useful, do not commend it to the general practitioner.

Nevertheless, in the cases for which it is suited it is pre-eminently useful; and this has been generally recognized in Europe, where all the larger cities now have special institutions for the Finsen light treatment. St. Petersburg, for instance, has no less than three,[1] and through the bounty of the queen a very perfectly equipped one has recently been opened in London. We are certainly behindhand in America. The light treatment is used by a few individuals, and some private institutions are equipped with facilities for its employment; but nothing has been done on a large and efficient scale for the sufferers for whom this method affords the best, and sometimes the only means of relief. I know of no institutions comparable to those on the continent, not to speak of the very large and excellent hospital at Copenhagen.

INDICATIONS FOR THE USE OF ACTINOTHERAPY.

The indications for the employment of actinotherapy have become more precise, though its field has been but little enlarged. The tubercular affections of the skin in all their varieties, lupus vulgaris, tuberculosis verrucosa, scrofuloderma, tubercular ulceration, postmortem tubercle, etc., together with some possibly tubercular affections such as lupus erythematosus, are the diseases in which it is pre-eminently useful. It would lead us entirely too far to review all the reports that have appeared on this subject during the year. A publication of Finsen's, however,[2] must convince the most skeptical of its efficacy. It consists of about twenty-five reproductions of "before and after" photographs of cases, showing results in most virulent, extensive and long-standing cases that can only be characterized as wonderful. The most terrible deformities are definitely replaced by smooth and innocuous scars; and milder cases show hardly any traces of their past disease at all. It is worthy of note here, though of course no one would for an instant doubt the entire reliability of the reproductions, that the patients pictured do not, as has been the case with some of the cures published here, wear exactly the same clothes and trinkets, and have exactly the same arrangement of the hair, etc., in the two photographs taken six months or a year or more apart.

CURES REPORTED.

Series of cures have also been reported by Gunni Busck,[3] Morris and Doré,[4] Kaiser,[5] von Petersen.[6] Huber,[6] François,[6] Leredde and Pautrier,[7] Chatin and Carle,[8] Montgomery,[9] Schmidt,[10] Dryer,[11] Jansen,[12] de Beumann and Degrais,[13] Rogers,[14] and many others. My own testimony can only be confirmatory of these results. Tuberculosis of the skin in all forms can be cured by this method.

Millioz[15] claims to have cured tuberculosis of the joints by actinotherapy. Leredde[16] has employed it with great success in obstinate acne. A few experimenters have used it in tuberculoses of the internal organs, rodent ulcer, epithelioma and cancer, alopecia areata, nevus, etc. We are still not in a position to make any positive statements of its efficacy in these complaints.

In this connection, a word concerning the frequency of lupus and other dermal tuberculoses in this country will not be out of place. The impression prevails that they are of extremely rare occurrence. I very greatly doubt its correctness. We see a number of cases in New York, and by no means exclusively in the foreign-born population. It was believed to be extremely rare in Denmark until Finsen began his work. Yet of the 1,200 or more cases that he treated almost all were natives of that small kingdom. The difficulty is that almost all the cases occur in the very poor, and can not be subjected to a long and expensive office treatment. I have seen perhaps 30 cases in the last two or three years; only ten or twelve of them could undertake treatment, and in some even of these it could not be kept up for the requisite length of time.

THE CHEMICAL RAYS.

In the early efforts at elaboration of the actinotherapeutic methods the pre-eminently chemical rays in the violet and ultraviolet end of the spectrum were regarded as the chief or indeed the only ones that it was desirable to employ. It was evident, of course, that the thermic rays of the red end had to be eliminated as much as possible; the patient's sensibilities soon settled that. The ordinary visual rays of the yellow region and its neighborhood were also looked on as useless; and hence obstacles to their passage, violet or purple glass screens or water-baths with similarly colored media were extensively employed. The method was even called the blue light treatment; some still use that term for it, and others believe that any blue or violet light or spark, no matter from what source of energy, will be efficacious. That position has been virtually abandoned during the past year. The best operators use all the rays of concentrated light, excluding only the red thermic rays so far as may be possible. It is true that the violet and ultraviolet rays are most active, both chemically and bactericidally; but those of the central spectral region are also effective, and there is great loss of power from their absence.

VARIOUS FORMS OF APPARATUS IN USE.

As regards the various forms of apparatus that can be employed, a word of warning is urgently needed. It is a common mistake to take superficial surface reaction as a measure of the efficiency of a machine, and some of the manufacturers do not hesitate to exploit this argument for their advantage. It was attempted with me in the cases of the German dermo-lamp and some of its native imitations. As a matter of fact it would rather be proper to say that surface reaction is in inverse proportion to surface effect. A lamp that causes reddening of the skin after an application of a few seconds, is one in which all the chemotactic effects of the rays are spent on the superficial epidermic layers. Finsen, Bie, and others have taken occasion in a number of communications to emphasize these facts, and to protest against the employment of entirely insufficient and inefficient light sources. There are lamps on the market, both here and abroad, that are entirely useless from a dermatotherapeutic point of view, not to speak of action on the deeper tissues. Some of these are composed of collections of ordinary incandescent lamps run on the ordinary light wiring. They are a delusion and a snare so far as the Finsen method is concerned; for, no matter what their candle-power, or in what numbers they may be combined, their amperage is too low, and they give thermic and visual, but not chemical and bactericidal effects. This can be readily proved by testing with ordinary sensitized paper; chemical action is slow, weak and inefficient, and the very slightest obstacle interferes with it altogether.

Similar if not quite so severe strictures must be made

on the smaller and cheaper arc lamps which are run on currents of from 5 to 10 amperes. There is not power enough in them to get deep effects. Arcs running on a 40-ampere current are as weak as can be used. I employ a 50-ampere arc; the regulation Finsen arcs need 60; and the originator of the method used a 100-ampere arc for his work.

With an efficient arc as the source of light, the surface reaction is usually very slight. There is a slight transitory erythema after each treatment, and a deep though not permanent pigmentation finally appears at the margin of the area that is subjected to it. But penetration occurs, and we can hope to affect not only the subcutaneous but also the deeper tissues. This point was settled by the experiments that I made some two years ago, and an account of which was published in the *Medical Record* at that time. Concentrated arc light, that had passed through the entire thickness of the human chest and abdomen, was successfully employed to make a print from a negative on a sensitive plate. The light had to pass through two layers of skin and subcutaneous tissue, fat, muscle, bone, and the red blood, before it could reach the plate; yet a distinctly marked chemical effect was obtained, and successful diapositives were made.

I have elsewhere described the apparatus that I employ, the actinolite, which is the only apparatus manufactured here that has sufficient power to be effective. A very important practical improvement has been made in it during the past year. The water bath required to cut off the heat rays is no longer a separate receptacle. The two condensing lenses are arranged to form the sides of the bath, the water being between them. Several important advantages are thus obtained. There is one piece less of accessory apparatus, and less weight. Then the entire optical part of the apparatus, the lens-waterbath, can be lifted out for changing the water and cleaning the lenses; it is all perfectly and readily accessible. Finally, and most important, all danger of cracking the lenses from their sudden heating up is entirely obviated by their being in contact with the water. It is decidedly discouraging to break lenses worth from $50 to $100 in one's work; and it is tedious to have to take ten minutes in running up the rheostat when one begins to work. I now go up to full power in 10 seconds or so without the slightest danger of damage. I have now used this modified lens-bath daily for five months, and am well satisfied with it.

The new iron carbons for the lamps that were proposed by Bang and others last year have not proved so effective as was hoped. Bogrow[17] claims that they burn irregularly, and are difficult to keep adjusted. I have found similar difficulties with the iron-manganese carbons that are on the market here; the white smoky vapor that they produce is objectionable. The idea underlying their employment, of course, is to obtain a more powerful blue-violet spectrum from the incandescence of these metals. As stated above, however, the tendency now is to employ almost the entire range of the spectrum; and there is no special reason for using a form of carbon otherwise disadvantageous for the purpose of obtaining a few more violet rays. I propose in the future to employ the ordinary arc carbons.

LIGHT PENETRATION OF THE SKIN.

Finally, there remains to be mentioned the efforts that have been made to favor light penetration of the skin by methods other than the inconvenient and often inapplicable compressors. Dreyr[18] found that the addition of a little erythrosin to nutrient media rendered the bacteria and infusoria in them sensitive to the yellow and green rays, just as it does the photographic plate. Thus, a layer of skin 1.25 mm. thick protected a non-sensitized prodigiosus culture, so that they lived under the light for 11 hours; when the medium was sensitized they were killed in 20 minutes by the same light. In lupus he got a much quicker and greater effect when he used a 1 to 1,000 sterile erythrosin-Grübler solution in physiologic (0.8 per cent.) salt solution. From 0.5 to 1 cubic centimeter was injected after Schleich's method to sensitize an area of from 4 to 6 square centimeters. Four to six hours later, the actinotherapy was applied; vigorous reaction was obtained in 15 minutes in well-vascularized tissue. I have had no personal experience with the procedure. It would probably be impracticable to give the injection several hours before each treatment in any but hospital cases; but if the erythrosin could be applied in some absorptive medium by the patient himself, it might be used.

144 West Forty-eighth Street.

THE DIVIDING LINE BETWEEN THE NEUROSES AND THE PSYCHOSES.*

RICHARD DEWEY, M.D.
WAUWATOSA, WIS.

The temptation to mark out new lines in the field of psychiatry is one that assails all who write on this many-sided subject, and every writer yields to it, the difference being mainly in the completeness of the surrender.

One must classify indeed to write at all, and classification is an alluring and agreeable exercise. Yet I shall indulge in it only to a very limited extent, even though there are few barriers as yet erected in the neuronic territory to keep us from wandering at will. Classifications have, furthermore, contributed much to neurologic and psychologic gaiety, which, in itself, is perhaps a good thing. With all possible respect, one may liken the classifications to a flock of geese, each one of which, however, is to its particular proprietor, a beautiful swan.

Beside the enjoyment to be gotten out of classifications, there is a more substantial good. Doubtless each new effort contains a germ of truth or a new ray of light or a suggestion of interest, and we need discussion and clarification of ideas, admitting that there is as yet no finality, and will not be until we can say more exactly what the brain conditions are which produce mental changes. The disposition, therefore, is natural to shuffle the pack and deal the cards anew, and play the hand as well as one can. The faces of the cards are ever the same, yet the permutations and combinations are infinite in variety. This game, however, is unlike games of chance. The honors are never "easy" and do not come by accident.

Recently, in a meeting of the Section of Psychology of the British Medical Association, Dr. Charles Mercier[1] presented a paper on the classification of insanities embodying his ingenious and familiar ideas as to forms and varieties. Dr. W. Lloyd Andriezen discussed the paper, or rather spoke after it had been read, but without referring to any of the points adduced, utilized the occasion to bring forward his own classification and explain its advantages.

More recently, in the Boston Society of Psychiatry and Neurology, Dr. Charles L. Dana[2] read a paper entitled "The Partial Passing of Neurasthenia," in which he proposed a reclassification of the insanities with inclusion among them of a large section of the hitherto so-called neurasthenias. Dr. Dana's lines of classification, like those of Andriezen, were drawn on an evolutionary basis, which, no doubt, is generally regarded as the safest and most practical foundation for present research. Dr. Dana states that there has been a "renaissance" in psychiatry, and that the good effect has been felt by the neurologist leading to a "more careful study of mental states," which has emphasized the fact that while insanity is "a morbid state, there is a large number of such states that are not insanities, though showing a kinship to them." He would, however, include the so-called neurasthenias which have mental weakness or disorder as their essential characteristic among the mental diseases.

Dr. Dana's proposal emphasizes the fact that insanity has never been satisfactorily defined. He thinks that one-half of the cases now called neurasthenia, including all the hysterias, would thus disappear from among the neuroses and reappear among the psychoses, but makes it clear that if there be a dividing line between neuroses and psychoses, insanity exists on both sides of this line, so far as the views now generally prevailing are concerned. It is also true that in adding certain cases of neurasthenia to the insanities he is adopting a view that has long been entertained by alienists.
